Two main methods of plasma insulin assay have been investigated for practical application The first of these is an in-vivo method using alloxan diabetic, hypophysectomised, adrenalectomised rats (Bornstein 1950) These rats are difficult to prepare, and the mortality rate during the preparation is high, in addition many variable factors enter into the final calculations, increasing the possibility of experimental error

The in-vitro method, using the rat diaphragm, is technically easier and more satisfactory Gemmill (1941) demonstrated the uptake of glucose, by the isolated rat diaphragm, from a buffer solution and the deposition of glycogen in the muscle The process is accelerated by the addition of small quantities of insulin to the buffer solution, and a quantitative relationship between the amount of insulin present and the uptake of glucose by the muscle was established by Stadie and Zapp (1947) and Krahl and Park (1948)

As a result of experiments on young healthy men, Vallance Owen and Hurlock (1954), using the rat diaphragm, obtained fasting plasma-insulin levels of 31-82 micro units per ml in healthy people

With these figures indicating the range of normality a diagnostic assay was made on the patient whose case report appears below

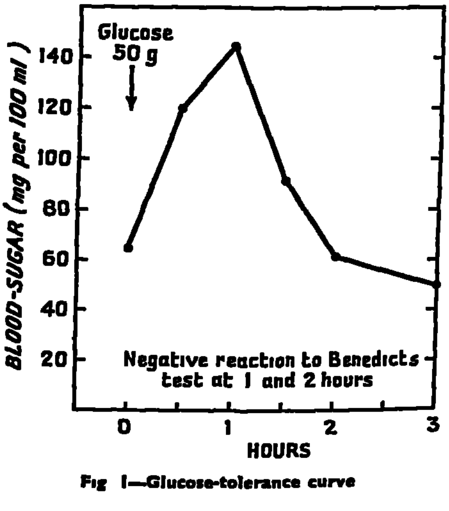

Fig 1—Glucose-tolerance curve

Case-report

A man, aged 33, was admitted semiconscious to St James' Hospital on April 3, 1955 His wife stated that he was subject to fits, the last one having occurred four hours previously more than 60 than in the younger patients Although breast cancer is more rapidly fatal if it begins at the age of more than 60, there is more chance of prolonging survival in this age group by hormone therapy when metastases are widespread

Assessment of improvement was made as objective as possible Temporary regression of metastases in glands, photographically recorded improvement in skin lesions and radiographic evidence of bone healing were accepted as beneficial effects of hormone therapy 5 cases were regarded as improved because pain of bone secondaries was diminished although no radiographic improvement was seen during long periods of survival in moderate health Only 4 of 35 patients with bone secondaries treated with androgen showed radiographic evidence of bone healing This figure of 11% compares unfavourably with 30% claimed by Hallberg et al (1953) who also claim improvement in general condition and palliation in 85% In the present series objective improvement was seen in 30% of those treated with androgen—a very similar figure to 27% found in a shorter observation period by Segaloff et al (1951) in 48 cases treated with *testosterone propionate 100 mg thrice weekly.*

Subjective improvement was noted in a few other patients in this series treated with androgens but it was doubtless partly due to the anabolic effect—increased appetite and temporary euphoria

For some old patients who present with fungating lesions too advanced for surgery or X-irradiation œstrogens are a useful means of palliation Healing of ulceration in some cases may last months

Huseby (1954), who treated with œstrogens 100 patients with advanced mammary cancer reported that those in whom the response was favourable had an average survival of 29 months from the start of therapy, and that 24 of these were more than 5 years past the menopause (natural or therapeutic) The response of those with bone lesions was poor Only 1 of his 5 patients who had not reached the menopause improved There was major regression of pulmonary metastases in 11. These figures are similar to my finding in 14 patients who improved with œstrogens Their average age was 63 (range 53–76) and average survival 32 months from the start of therapy

The considerable virilisation caused by big dosages of androgens is perhaps not so very important Shaving with an electric razor will maintain a presentable appearance Methyl androstenediol which is claimed to be less virilising has nothing to recommend it over testosterone Patients treated with 100 mg of methyl androstenediol daily for some months developed almost as much hirsutism as those given testosterone esters. moreover methyl androstenediol causes pain when it is given in crystalline suspension and in several cases it caused an abscess at the site of injection Segaloff et al (1952) observed similar results and achieved regression of the lesions in only 2 of 24 cases treated solely with methyl androstenediol

The choice of therapy was not dictated at first by a knowledge of œstrogen dependence of a particular cancer Usually old postmenopausal women with soft-tissue metastases were treated with œstrogens, and the younger patients or those with widespread bone metastases were given androgens Subsequent analysis of the 17 patients who responded to androgens, however, showed that 82% had had their first symptom of cancer before the menopause, whereas of the 14 who improved with œstrogens 93% had had their first symptom after the menopause This may possibly be a guide to selection for hormone therapy, and in the androgen-treated group with premenopausal onset this may indirectly indicate œstrogen dependence or conversely, the postmenopausal onset suggests that not even stroma-cell œstrogens were responsible stimulants to their cancer (Sommers et al 1953) In these old patients in whom pituitary activity is not inhibited by endogenous œstrogens, there may be excessive production of somatotrophin and prolactin as well as gonadotrophin, and the beneficial effect of œstrogen therapy may be due to inhibition of these hormones

It is quite clear that there is a type of patient with breast carcinoma which is temporarily responsive to treatment with androgens or by oöphorectomy or by adrenalectomy and that the essential common factor is œstrogen dependence (Pearson et al 1954) Unfortunately there is no way of detecting œstrogen dependence and only recently have chemical methods of estimating œstrogens in urine been elaborated but the method is laborious (Brown 1955) and is not yet readily adaptable to clinical use

In the present series the patients were so widely riddled with metastases that one could not hope for much benefit. hence an improvement-rate of about 30% for both œstrogens and androgens is possibly satisfactory

As Asher (1955) aptly remarked ' Prolongation of life is not the only aim of treatment. it should be a tolerable life It is better to be wholly alive for one month than half alive for two The latter part of his statement referred to cases after endocrine surgery, which like hormone therapy at present suffers from an inability to discriminate between cancer cases with and without hormone dependence

In the present series the side effects and possible upsets and the prolonged course of oft repeated intramuscular injections were a high price to pay by patients for no improvement perhaps it would have been better if they had been allowed to spend their remaining life under increasing doses of morphine So much however depends on each patient's temperament One can only remember the gratitude and faith of those who were fortunate in their response to treatment some of whom enjoyed many months' freedom from pain and freedom from odour, and lived reasonably normal lives Such results even though restricted to about a third of those treated, are worth while

Summary

106 women with stage IV mammary carcinoma were treated with either androgen or œstrogen and kept under observation until death

Improvement was observed in only 29% of cases Of the 17 women who improved with androgen 14 had had their first symptom before the menopause and of 14 patients who improved with œstrogen 13 had had their first symptom after the menopause

The average age of those patients who received benefit from œstrogen was 63 and from androgen 49 The prognosis was better for the older patients treated with œstrogen the average survival for these being 32 months compared with 17 25 months for those who improved with androgen

The possible significance of œstrogen dependence in the younger group and pituitary-hormone dependence in the older postmenopausal patients is discussed

My thanks are due to Sir Charles Dodds, who persuaded me to join in the British Empire Cancer Campaign œstrogen trial, the British Empire Cancer Campaign for a grant for three years for laboratory assistance, Prof Milnes Walker for permission to treat patients in the department of radiotherapy at the Bristol General Hospital the physicians and surgeons who allowed me to treat their patients, Miss G M. Jeffree, my technician, Dr C H. G Price and Dr. A L Taylor for advice and help and Miss J. E Nixon, of the records department of the department of radiotherapy, for much secretarial help The androgens were provided by Ciba Laboratories, Organon Laboratories Ltd, and British Drug Houses Ltd.

References overleaf

insulin assay is of most use in these cases, the other causes will usually be recognised during the course of clinical and laboratory investigations

Glucose metabolism in the body depends on the hormonal balance between the pancreas, pituitary, and adrenal glands, and an abnormal blood-sugar level only indicates hormonal imbalance and not dysfunction in one particular gland For this reason a low blood-sugar level may not reflect pancreatic hyperactivity

In some cases, as in the present one, because of compensatory mechanisms the blood sugar level may not drop below *50 mg per 100 ml*, and immediately one of the triad of criteria of Whipple and Frantz (1935) is not fulfilled, although a tumour is present

"Plasma-insulin" assay obviates the risk of these variable blood sugar levels and differentiates between organic hypoglycæmia (due to an islet cell tumour) and so called functional hypoglycæmia In the latter the fasting blood sugar is normal but becomes subnormal two to six hours after the ingestion of carbohydrate In contrast to this, organic hypoglycæmia always occurs after a period of fasting, and the fasting blood-sugar is persistently low

Summary

In a case of spontaneous hypoglycæmia due to an islet cell tumour of the pancreas, plasma insulin levels were assayed before and after operation

By means of plasma-insulin assay the diagnosis of islet cell tumour can be confirmed, and the causes of spontaneous hypoglycæmia differentiated

I am indebted to Dr Vallance Owen and his colleagues for the plasma insulin assays, Mr Norman Tanner, who operated, Dr G T Allen and Dr P W Kippax, who reported on the specimens, Miss E Mason, who prepared the graphs and photographed the specimen, Dr R J Harrison, without whose advice and encouragement this article would not have been written, and Dr M Bewlay, who originally diagnosed the case

ARTIFICIAL INSEMINATION AFTER INTRATHECAL INJECTION OF NEOSTIGMINE IN A PARAPLEGIC

Ralph Spira
M D Paris, L R C P E
CHIEF MEDICAL OFFICER, REHABILITATION CENTRE,
TEL HASHOMER GOVERNMENT HOSPITAL, TEL AVIV, ISRAEL

In 1949 Guttmann reported that intrathecal injection of neostigmine in male patients with traumatic paraplegia induced erection of the penis and ejaculation of spermatic fluid Neostigmine administered by other routes has not been shown to have this effect

Guttmann injected neostigmine intrathecally in order to test the spermatic fluid and to control the progress of hormone treatment in paraplegics, and in 5 cases he used this method to obtain semen for artificial insemination, which, however, did not result in pregnancy

The technique of the neostigmine test is simple 0 2 mg of neostigmine in 1 1000 aqueous solution is injected intrathecally at L4–L5 vertebral interspace, the injection is made slowly after mixing the contents of the syringe several times with the cerebrospinal fluid After the injection the patient lies supine or on his side without a pillow About an hour after the injection erection followed by several ejaculations of spermatic fluid takes place Specimens are sent for examination

The injected neostigmine acts presumably on the undamaged spinal centres in the lumbar cord, below the level of the lesion, which control erection and ejaculation In addition the neostigmine temporarily diminishes the reflex activity of the isolated spinal cord, this effect manifests itself by diminished spasticity of the paralysed limbs In some cases there are other side effects, such as a decrease in the systolic and diastolic blood pressure, headache, nausea, and general weakness, all these *effects disappear after two to three hours*

I have injected neostigmine intrathecally for testing purposes, and in one case for the purpose of fertilisation Pregnancy resulted

Case-report

A man, aged 25, in 1948 sustained a fracture dislocation of T6 vertebra, resulting in a complete spinal syndrome at T6 segment He remained spastic with pronounced flexion and adductor spasticity In the early stages of his disability he had repeated attacks of severe bilateral orchitis, which responded to treatment He had from time to time had spontaneous erections without ejaculation The urine, routinely examined, sometimes contained a few spermatozoa

Neostigmine Tests —The first neostigmine test, before the patient's marriage in October, 1952, revealed only 500,000 spermatozoa per ml, with no motility A further test, in April, 1954, showed an improved count of 20 million spermatozoa per ml, 15% of the spermatozoa were motile, and there was considerable microspermia

Treatment —Testosterone 25 mg daily for fourteen days and gonadotrophin (Winthrop) 1000 units daily for four weeks were administered in order to improve the count sufficiently for an attempt at artificial insemination

Attempted Fertilisation —The first attempt at fertilisation was made in June, 1954 At the patient's request artificial insemination was not undertaken After intrathecal neostigmine he was left with his wife, and the induced erection was used for coitus This attempt did not result in fertilisation A specimen of semen recovered from one of the ejaculations showed a count of 10 million spermatozoa per ml, of which 10% were motile The decrease in the count, compared with that before hormone treatment, was apparently due to a "rebound phenomenon," associated with the administration of both testosterone and gonadotrophin From then onwards he was given 1000 units of gonadotrophin alone daily for four weeks A second unsuccessful attempt at impregnation was made under similar conditions in August, 1954

Artificial Insemination —The third attempt was made in November, 1954 This time artificial insemination was undertaken by a gynæcologist with a specimen obtained after intrathecal injection of neostigmine No spermatic count was taken This also proved unsuccessful The fourth attempt was made on Dec 4, 1954 This resulted in pregnancy, and the patient's wife was delivered of a healthy daughter on Sept 3 1955 When in March, 1955, it became obvious that his wife was pregnant, the patient's spermatic count was checked it amounted to 200 million per ml, of which 50% were motile

Confirmation of Paternity —Blood tests gave the following results

Father	Group A Rh′+, RhO+, RH″–, HR′+
Mother	Group A RH′+
Infant	Group A RH′+

Conclusions

So far as I know this is the first reported case of successful impregnation by the spermatozoa of a paraplegic after intrathecal injection of neostigmine In the present case impregnation would otherwise have been impossible, as there was no chance of spontaneous ejaculation There are of course well authenticated instances of fatherhood in spinal paraplegics without neostigmine having been administered (Freeman, unpublished and our own cases), but these cases have been in paraplegics with preserved faculties of coitus and ejaculation

This method opens an important new field in the physical and psychological rehabilitation of paraplegics

I thank Dr J Gordon chief medical officer, ministry of defence, for permission to publish this article, Dr C Rosen

MEAN SERUM CHOLINESTERASE LEVELS IN FOUR GROUPS OF ADULTS

Group	*No of* subjects	Mean activity (*µl of* CO₂ per ml *serum* per min)	Standard *error of* mean	Range
Healthy adults	33	76	±2	53–102
Non-obese diabetics	25	81	±3	51–120
Obese diabetics	25	107	±7	43–175
Obese non diabetics	25	102	±5	60–131

diabetics, 15 (60%) gave values above this range, varying from 108 to 175 µl , 9 of them (36% of the whole group) gave values over 120 µl The mean value obtained in the 25 obese non diabetic patients, as in the obese diabetics, was significantly higher than that found in the healthy adults, *11 of them (44%) having values ranging from* 105 to 151 µl On the other hand, of the 25 non-obese diabetics 23 (92%) had levels within the normal range, and no levels were above 120 µl

Statistical analysis of these results shows that, although 2 of the non obese diabetics gave values above the highest found in the present normal series, there was no statistical difference between the levels in the non obese diabetics and those in the healthy adults On the other hand, the difference between the levels in the non-obese and the obese diabetics is highly significant, *as is also the difference* between those in the obese non-diabetics and the healthy adults

No *significant correlation* was *found between the* serum-cholinesterase levels in the diabetic group and the severity or degree of control of the diabetes

Discussion

Although the serum-cholinesterase level in children is significantly higher *than in adults* (McArdle 1940), Callaway et al (1951) reported that age does not influence the level in adults Many workers have also shown that the plasma-cholinesterase level does not significantly differ between the two sexes The patients studied in the present series were all over the age of 18, and the mean *serum cholinesterase* level of 76 µl of carbon dioxide per ml of serum *per minute found in our healthy adults* agrees with the average normal values of 78, 65, and 79 µl found by McArdle (1940), Kunkel and Ward (1947), and Hutchinson et al (1951) respectively The results we obtained in diabetics indicate that high serum-cholinesterase levels are found only in patients who are also overweight, and they suggest that the high levels are associated with the accompanying obesity, rather than with the diabetic state itself , this accords with the finding by Berry et al (1954) of a positive correlation between the amount of surface fat and the plasma-cholinesterase level

The influence of diet on plasma-cholinesterase activity in man was first studied by McCance et al (1948), who reported a reduction in the serum-cholinesterase level in undernourished Germans (see also Hutchinson et al 1951) *Waterlow (1950)* found very low *plasma* cholinesterase levels in 20 malnourished African infants In 2 of them he measured liver cholinesterase *activity in* aspiration-biopsy specimens In both the initial liver-cholinesterase level was low compared with that in 4 *controls*, but it was more than doubled after the infants *were fed for* four to five weeks on a *high-milk* diet Hutchinson et al also found that a rise in the plasma-*cholinesterase* level was brought about by improvement of the diet

There is now good evidence that the plasma cholinesterase is, in the main, derived from the liver McArdle (1940) demonstrated that the serum cholinesterase level is lowered in patients with liver disease and that improvement in liver function was accompanied by *a rise* in the serum cholinesterase level

Brauer and Root (1946) further showed that, in rats with liver injury induced by intraperitoneal injections of carbon tetrachloride, both the plasma and liver cholinesterase levels were reduced , *after ten days' injections, the reduction was* more pronounced in the liver

The cholinesterase activity of human plasma is predominantly due to " pseudocholinesterase " (Mendel et al 1943), an enzyme differing in many respects from the " true " cholinesterase present in nerve and muscle tissue, whose physiological function is *presumed to be* the inactivation of acetylcholine released at certain nerve endings The function of pseudocholinesterase is at present obscure, but the above observations raise the question as to whether in plasma, and therefore also in the liver, *pseudocholinesterase may* not be concerned with some aspect of fat metabolism, rather than with inactivating acetylcholine It is known that the pseudocholinesterase level in the plasma can be reduced almost *to zero without signs of acetylcholine accumulation* developing (Mazur and Bodansky 1946, Hawkins and Gunter 1946) It is *also* known that pseudocholinesterase hydrolyses various non-choline esters, and Adams and Whittaker (1949) showed that it is responsible for about 90% of the hydrolysis of tributyrin by human *plasma*

Further *evidence suggesting a connection* between pseudo cholinesterase and fat metabolism was afforded by Hawkins and Nishikawara (1951), who showed that in male rats the *ingestion of a hypolipotropic diet led to a considerable rise* in pseudocholinesterase activity in both the plasma and the liver , the subsequent addition of lipotropic agents, such as *choline or methionine, to the deficient diet restored the elevated* plasma pseudocholinesterase level *to normal* In the rat, the *plasma contains, in addition* to pseudocholinesterase, an active true cholinesterase and also an eserine resistant tributyrin-hydrolysing enzyme , *neither of these enzymes* is affected by *giving hypolipotropic diets It* is also of interest that Kunkel and Ward (1947) found that the plasma pseudocholinesterase level is higher than normal in patients with the nephrotic syndrome, the *average in the 10* patients studied being 110 µl of carbon dioxide per ml of serum per *minute*

On the other hand, denervation experiments and the use of selective inhibitors tend to show that in certain other tissues, pseudocholinesterase, like true cholinesterase, may play some part in cell excitation *Supporting* evidence for this has been obtained from experiments on the central artery of the rabbit's ear (Armin et al 1953), cat ileum (Koelle et al 1950), cat skin (Hellmann 1952), cat iris (Burn and Philpot 1953), dog heart (Burn and Walker 1954), and cat brain (Desmedt and La Grutta 1955)

It is possible therefore, that, owing *to the overlapping* substrate specificity shown by *many of the* esterases, the term " pseudocholinesterase " is being used to denote *different* enzymes with fundamentally *different physiological* properties, and that the pseudocholinesterase in human plasma and liver *may* be very different from that in the nervous system, the myocardium, the *blood*-vessels, or the intestinal wall

Summary

The serum-cholinesterase level was determined in 50 *adult patients* with diabetes mellitus (25 obese and 25 non-obese), 25 adult *obese* non-diabetics, and 33 healthy non obese adults

High serum cholinesterase levels were found only in those *diabetic* patients who were also overweight, suggesting that elevation of the serum-cholinesterase level is associated with the accompanying obesity, rather than with the diabetes itself

The possibility is discussed that this pseudocholinesterase, *present in human* plasma and liver, may be concerned with some aspect of *fat metabolism*

We wish to thank the Medical *Research Council* for a grant towards the expenses of this work Our thanks are also due

A RAPID METHOD OF ESTIMATING FIBRINOGEN

ACUTE hypofibrinogenæmia occurring in pregnancy or after surgery is an emergency which requires rapid diagnosis and treatment The bleeding which then takes place can be rapidly fatal and is arrested only by intravenous injection of purified human fibrinogen, massive blood transfusion alone gives uncertain results Purified fibrinogen is scarce, and for economy it is essential to know the plasma-fibrinogen level before and during treatment Many methods for the quantitative estimation of fibrinogen have been described, but none of these combines accuracy with the simplicity and speed needed for such emergencies The method described below is accurate, simple, and quick, the result is obtained within 25 minutes of receiving the blood

Method

The coagulation temperature of fibrinogen is about 55°C in neutral solutions[1] Other plasma-proteins are coagulated at temperatures exceeding 60°C It was found that the turbidity produced by heating saline dilutions of plasma at 56°C is directly proportional to the fibrinogen concentration and that it remains constant for many hours, even after twenty-four hours the original turbidity can be restored by shaking The result has been expressed in terms of the barium-sulphate standard used by Kunkel[2] for his zinc sulphate turbidity test, so that this method can be adopted in any laboratory without further estimation of fibrinogen by Kjeldahl analysis

Procedure

Plasma is obtained from blood to which has been added 2 mg per ml of either the oxalate mixture of Heller and Paul or 'Disodium Sequestrene' 0 2 ml of plasma is thoroughly mixed with 3 ml of 1% sodium chloride in each of two half-inch diameter test-tubes One of the tubes is placed in a water-bath at 56°C for 15 minutes The extinction reading of the heated mixture is measured against the unheated blank in the 1 cm cell of a spectrophotometer set at 650 mµ At this dilution 1 Kunkel unit is equivalent to 42 8 mg of fibrinogen per 100 ml in the plasma sample

Comments on the Method

Measurements at timed intervals have shown that a constant turbidity is always obtained after 15 minutes at 56°C

Different dilutions of plasma are required if the fibrinogen content is much higher or lower than normal Serial dilutions of plasma were heated at 56°C, and it was found that, when the turbidity exceeded 20 Kunkel units, its relation to the fibrinogen content was no longer linear A plasma-fibrinogen level above 850 mg per 100 ml produces a turbidity greater than 20 Kunkel units when diluted 1 in 16 and requires further dilution—e g, 1 in 31—to obtain accurate results Fibrinopenic plasma gives a faint turbidity at a dilution of 1 in 16, therefore a less dilute mixture is desirable—e g, 1 in 11, or 1 in 7 The result is calculated from the formula given below

A 'Unicam SP 350' spectrophotometer was used for these experiments, but any photo-electric colorimeter or spectrophotometer may be used It should be calibrated at 650 mµ (or with 'Ilford filter No 608') with the barium-sulphate standard used by Kunkel[2] 1 Kunkel unit is equivalent to 26 8 µg per ml of fibrinogen in the diluted plasma The concentration of fibrinogen in the undiluted plasma can therefore be calculated from the formula

$$F = 2\,68 \times \frac{(Vs + Vp)}{Vp} \times \frac{(Et \times 20)}{Ek}$$

where Et = extinction reading of test, Ek = extinction reading of barium sulphate standard, F = fibrinogen content of plasma in mg per 100 ml, Vp = volume of plasma in mixture, and Vs = volume of saline solution in mixture

To find whether substances other than fibrinogen are precipitated at 56°C, many samples of serum were diluted and heated at this temperature These were from healthy people as well as from patients whose serum contained abnormal proteins or abnormal quantities of protein In none was there any turbidity The presence of dextran did not interfere with the result Dilutions of lipæmic sera which are clarified by heating to 56°C resume their original turbidity on cooling to room temperature, interference from this source is negligible if lipæmic samples are cooled under the tap before the turbidity is measured

Calibration of the Method

The fibrinogen content of 25 samples of plasma was estimated by micro-Kjeldahl distillation, the fibrinogen content of these samples was 197–534 mg per 100 ml Each sample was also tested by turbidity after heating at dilutions of 11, 16, and 31 For each of the 75 results a constant (K) was calculated by dividing the extinction reading by the concentration of fibrinogen in the diluted plasma From the mean value of K, which in these experiments was 597 × 10^{-3}, the conversion factor required to relate turbidity to fibrinogen content was calculated The standard deviation of K was 22 9 × 10^{-5} and the coefficient of variation 3 84% The greatest deviation from the mean for any result was 8%

I should like to thank Dr George Discombe for his advice and encouragement

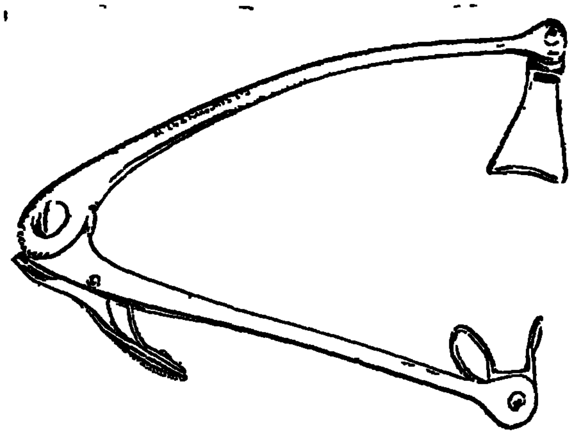
SELF-RETAINING RETRACTOR FOR VARICOSE-VEIN SURGERY

RETRACTION in the depths of a groin incision for juxtafemoral ligation has always been difficult The area is small, yet it is packed with thin-walled vessels which, if torn, can give rise to embarrassing moments The instrument shown in the accompanying figure has been designed to give an unimpeded field during the operation It renders tiring, and therefore unstable, hand retraction unnecessary in almost every case The shafts are curved in order to fit snugly to the upper thigh, while the wire-loop blades, which are gentle to the tissues, are pivoted at their point of suspension This ensures a consistently stable grip as the retractor opens along its very wide arc



I am grateful to Mr W J Cooper, of Messrs Allen & Hanburys, for his help

London, W 1

STANLEY RIVLIN
M.R.C.S

Necropsy Findings

The significant findings other than those in the heart were small stature, slight œdema of the lung, ante mortem thrombus filling the lumen of the splenic artery throughout its course, old infarctions of the spleen, thrombosis of the superior mesenteric artery with acute infarction of the lower half of the jejunum ileum, cæcum, and part of the ascending colon, accompanied by early peritonitis

The *heart* weighed 130 g All chambers were dilated and there was definite hypertrophy of the left ventricle The striking feature was the diffuse whitening of the endocardium and inner third of the myocardium of the left ventricle (fig 1) This was seen mainly on the anterior and lateral walls in the apical half of the ventricle, but it extended upwards on the posterior wall behind the mitral cusp The interventricular septum, except towards the apex, was unaffected There was no mural thrombus The aortic valve, the mitral cusps, and their chordæ tendineæ were normal, but the papillary muscles, both anterior and posterior, were fibrosed The endocardium lining the left auricle was distinctly thickened The foramen ovale was completely sealed off On the right side of the heart the endocardium and valves were normal but the right ventricle showed slight hypertrophy The coronary arteries showed no abnormality The pericardium and aorta were normal

Microscopy

Numerous sections of the heart showed focal fibrosis of the myocardium of the left ventricle The inner third was extensively involved, but the outer two thirds showed only slight damage Elastic tissue stains revealed fibroelastic thickening of the endocardium in the scarred area of the left ventricle (fig 2) In several places it was impossible to differentiate the endocardium clearly, owing to the fibroelastic change affecting both the endocardium and the subjacent myocardium The thickening, in general, was of mild degree The endocardium over the interventricular septum and in the right ventricle was normal In addition to the focal fibrous scars in the myocardium, there were numerous congested capillaries, occasional small areas of round cell infiltration, mainly lymphocytic, and also several foci of acute cellular infiltration including eosinophil polymorphonuclear leucocytes (fig 3) The myocardium in general was hypertrophied but there was some atrophy of the fibres immediately surrounding the scarred areas A few small foci of necrosis of the myocardium were present There was no evidence of rheumatic fever and in particular there were no Aschoff nodes The acute lesions of periarteritis nodosa were not seen in the coronary arteries or arterioles In a very occasional small artery in the subendocardial fibrous scars, however, a fairly marked fibroelastic thickening of the subintimal tissues was observed (fig 4) The pericardium showed a slight perivascular round cell infiltration

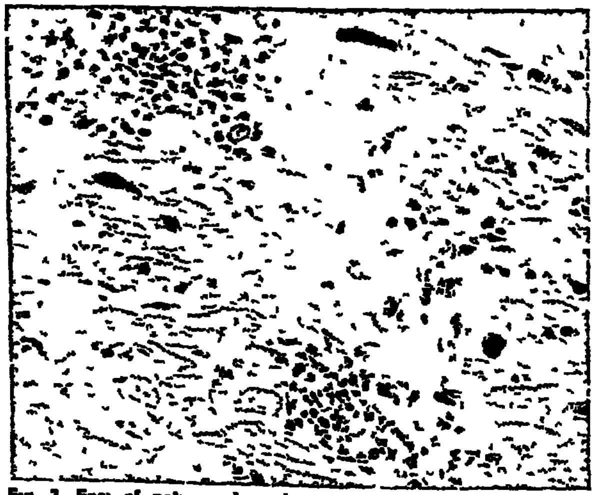


Fig 3—Foci of polymorphonuclear leucocytic infiltration of the myocardium (× 250)

The typical lesions of acute periarteritis nodosa were found in the superior mesenteric artery at the site of the thrombus formation Similar acute lesions were present in the vasa vasorum of the aorta, and in the vessels of the pancreas (fig 5) and testes Lesions in the healing phase with granulation tissue formation were seen in the wall of the splenic artery There was no evidence of periarteritis nodosa in the kidneys or in the liver The cellular infiltrate in relation to the acute vascular lesions was similar to that in the heart—i e, lymphocytes, plasma cells, and polymorphonuclear leucocytes, including eosinophils There were no other significant histological findings

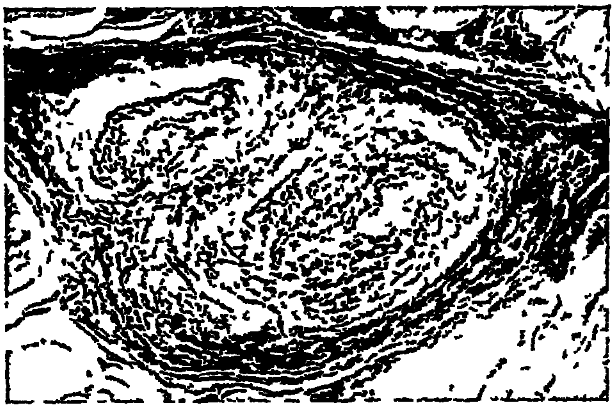

Fig 4—Two small subendocardial arteries showing fibroelastic thickening of the wall (× 140)

Comment

The sudden death was considered to be of cardiac origin and despite the age of the patient a tentative diagnosis of congenital fibroelastosis of the heart was made The clinical history of stunted growth since the age of 3 supported a congenital cardiac lesion The terminal illness with mid abdominal pain was explained by the superior mesenteric artery thrombosis with acute intestinal infarction The pre terminal illness with pain in the left abdomen was attributed to arterial thrombosis and infarction of the spleen These infarcts were several weeks old At the time of the necropsy the cause of the thrombosis in the superior mesenteric and splenic arteries was difficult to account for in the absence of any evident source of emboli Subsequent histological examination of these vessels disclosed the typical features of acute periarteritis nodosa The administration of sulphonamides, certainly on one occasion and possibly more than one, is of interest in view of these findings (Rich 1942)

Discussion

In congenital fibroelastosis of the endocardium, there is a typical macroscopic picture The endocardium is pearly white throughout one or both ventricles, usually the left, and this appearance was the striking post-mortem feature in this case But there are several findings not in accord with congenital fibroelastosis The

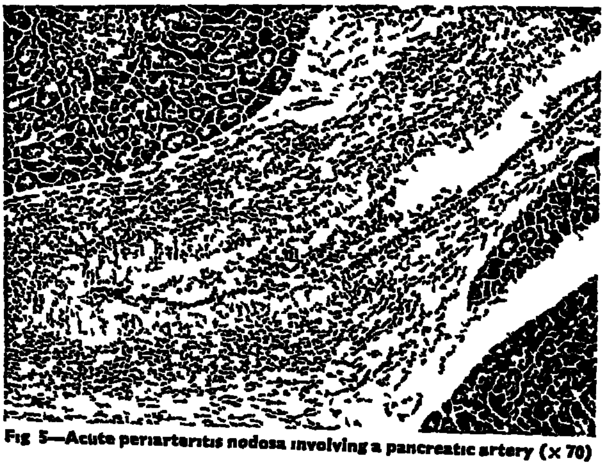

Fig 5—Acute periarteritis nodosa involving a pancreatic artery (× 70)

interested in the history of the theories by which men have endeavoured to explain disease or to heal their companions

Research Films in Biology, Anthropology, Psychology and Medicine

ANTHONY R MICHAELIS, PH D, technical director, Scientific, Industrial & Medical Photographic Laboratories Ltd, London New York Academic Press London Academic Books 1955 Pp 490 £4

BY describing in detail the film techniques available and by quoting many experiments in which they have been applied, Dr Michaelis hopes to encourage research workers to consider the use of film as a tool in their own work

He gives advice on cameras and camera stands for various tasks, types of illumination, the preparation of a film treatment and shooting script, and the use of time markers for obtaining quantitative results, of time lapse and high speed cinematography, of cinemicrography, and of X ray cinematography He even mentions the application of television as an image converter in certain circumstances

The section on the medical sciences occupies about a third of the text It is surprising to read, however, that in *1920* " not a single British surgical film could be named " in view of the fact that several surgeons, notably Alexander Don and Cecil Wakeley, had filmed operations before that date By 1929 films on such subjects as tuberculosis, venereal diseases, physiology, cytology, and health education were also available This section describes the techniques and equipment suitable for medical work, and their various applications in the investigation of locomotion, digestion, respiration, the genito urinary system, the circulation, the sense organs, neurology, pathology, and aviation medicine

There is perhaps too much detail in the book Descriptions of experiments are often accompanied by details of the scientific results derived from them, data that are surely readily available to the research workers for whom the book is intended And is Dr Michaelis right when he says that, in films other than those for personal analysis, no shot should exceed thirty seconds ? In the cinema and in television, Hitchcock and O'Donovan have shown that interest can be maintained in one shot for much longer, and the television interlude film of the potter's wheel is a well known proof to the contrary

If there is little in the book that is actually new, Dr Michaelis has collated information from most parts of the world where the cine camera is used for research, and his compilation of 1500 authors and references makes the volume the most valuable reference book now available in this field

Obstetrical Anesthesia

Its Principles and Practice B B HERSHENSON, M D, director of anesthesia, Boston Lying in Hospital Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1955 Pp 403 69*s*

THE administration of anæsthesia for obstetrics has in the past been largely left in the hands of obstetric residents or the more junior residents in anæsthesia This is an unsatisfactory state of affairs, and Dr Hershenson rightly places more faith in the competence and experience of a trained anæsthetist than in any special drug or method of anæsthesia Though he recognises that there is a real need for better drugs, he is forthright in his condemnation of the exaggerated emphasis often placed on a single agent as the safest or best method of anæsthesia in obstetrics

Dr Hershenson aims to help doctors in their selection of a technique for a particular case, and he presents a fairly full and well referenced account of the subject The accent is on general analgesia and anæsthesia but local methods are included The physiology of pain in labour, the pharmacology and selection of drugs used in obstetrics, diseases complicating pregnancy and labour, and asphyxia neonatorum are discussed in detail

The author is an anæsthetist, and his book will therefore be all the more welcome to those actively engaged in administering anæsthetics, since the literature of this subject has been written largely by obstetricians But *it is* a difficult book to read , there is much needless repetition and a great deal of elementary fact which one would like to assume every anæsthetist knows before he assumes responsibility for an obstetric patient It is also a pity that no recognition is given to the considerable amount of knowledge accumulated on this side of the Atlantic about the value and use of trichlorethylene as an analgesic in labour

Galen on Anatomical Procedures

Translated with introduction and notes by Prof CHARLES SINGER, F R S London Oxford University Press 1956 Pp 314 37*s* 6*d*

UNTIL recent years the works of the greatest and most prolific medical writer of antiquity were closed books to the modern reader Professor Singer has now added another to the few works of Galen which have been translated from the Greek into English

Galen's work entitled *De Anatomicis Administrationibus* is the text of lectures on anatomy delivered in Rome about A D 177 It thus preserves the very words of an ancient teacher The Greek text was translated into Latin in 1531, and in this form the work had a profound influence on Vesalius and *other great Renaissance anatomists Though Galen had* some knowledge of human anatomy, especially of the bones, most of his dissection was done on the rhesus monkey and the Barbary ape, in which many parts are greatly different from their counterparts in man Professor Singer has not only provided a scholarly translation of Galen's text, but he has also identified wherever possible the structures mentioned, and has given them their modern anatomical names

The book, which is illustrated, is a basis for the study of the sources available for the foundation of modern anatomy It has been published for the Wellcome Historical Medical Museum

---

Surgery of the Ambulatory Patient (3rd ed Philadelphia J B Lippincott London Pitman Medical Publishing 1955 Pp 866 96*s*)—This book from the University of Pennsylvania is divided into five sections Hrant H Stone describes anæsthesia, with particular attention to local and regional infiltration E J Pulaski deals with antibiotics and sepsis, and gives a refreshingly common sense exposition of the relations between organism, antibiotic, and patient H M Burros discusses urological conditions, and *Louis* Kaplan fractures and dislocations The main author, *L K* Ferguson, coordinates and completes the work with descriptions of techniques and equipment, soft tissue trauma, tumours, and a variety of lesions arranged according to the regions in which they arise It is an impressive parade of the types of case treated in the outpatient departments of the Pennsylvania University hospitals

The emphasis is on conditions which *the author* and his contributors have treated as ambulatory, but they allow themselves to discuss those which can *sometimes* be treated in the ambulant, and also similar conditions, to be distinguished from them, which require bed rest and admission to hospital More and more conditions are now being treated with the patient out of bed, so that there may soon be no limits to a book with this title The surgical reader will draw his own line between what he treats in outpatients and what he admits to hospital, and in this country he will probably include such conditions as flexor tendon suture, thyroglossal cyst, and supraspinatus bursa in those he prefers to keep under his own observation The advantages of early ambulation have to be balanced against the fact that rest is essential to tissue healing as it is to the resolution of inflammation

Individual surgeons will disagree with some of the details in this book, but, read with discrimination, it will be very useful in those hospitals where outpatient surgery is highly developed and under experienced supervision It includes a number of conditions, some of them not uncommon, such as mucous cyst of the nail fold, which have not, so far as we know, been described elsewhere in surgical literature Illustrations are copious clear, and often beautiful Advice on treatment is detailed and practical The catalogue of pathological conditions is exhaustive Lippincott's continue their policy of printing each page in two columns, and have produced the whole work accurately, generously, and attractively Not only those concerned with outpatient and accident surgery, but all general and orthopædic surgeons, will find something of interest and value in it

TABLE I—PATIENTS WITH DISORDERS GIVING RISE TO VOMITING IN PREGNANCY REQUIRING ADMISSION TO HOSPITAL, 1938–53

Disorder	No of cases	Disorder	No of cases
Pyelitis and urinary tract infections	72	Breech presentation	2
Pre eclampsia	7	Subarachnoid hæmorrhage	1
Diaphragmatic hiatus hernia	7	Hypertensive encephalopathy	1
Peptic ulcer	5	Cerebral thrombosis	1
Gastritis	7	Otitis media	1
Gastro enteritis	1	Influenza	1
Appendicitis	2	Pneumonia	2
Cholecystitis	2	Bronchitis	2
Pylorospasm	1		
Intestinal obstruction	3	Total	130
Infective hepatitis	2		
Constipation	2		
Accidental antepartum hæmorrhage	5		
Degenerating fibroid	3		

Of the 453 patients with hyperemesis, 305 lived in Aberdeen, they were studied separately because it was possible to calculate the incidence of the condition in that city The figures, of course, relate only to cases sufficiently severe to warrant admission to hospital, although many relatively mild cases were admitted, many more of similar severity may have been treated successfully at home, especially in the earlier years

All maternal deaths from hyperemesis in North east Scotland between 1931 and 1953 were also studied

Results

INCIDENCE

Table II shows the average number of patients with hyperemesis admitted per year and the percentage of cases in which pregnancy was terminated

These figures suggest that the condition became less common and less severe between 1940 and 1948, and this is confirmed by the data for Aberdeen in table III In Aberdeen the rate of admissions fell sharply from 10 per 1000 births in 1938 to less than 3 per 1000 in 1940, and it remained low until 1949, when the pre war level was almost regained, since then the rate has fluctuated between 6 and 10 per 1000 births

Pregnancy was terminated in 7 cases (13 7%) in 1938–39, but in the five year period 1940–45 only 3 pregnancies were terminated (3 8%) Since 1949 the proportion of pregnancies terminated has risen again, but it is still a little lower than the pre war rate Over the whole period, the rate of admissions due to hyperemesis in booked cases was 7 7 per 1000 births in primigravidæ, and 9 9 in multigravidæ

TABLE II—PATIENTS ADMITTED TO HOSPITAL WITH HYPEREMESIS, BY YEARS

Years	Patients admitted with hyperemesis	
	Av no per year	Pregnancies terminated (%)
1938–39	33	12
1940–45	19	6
1946–48	25	8
1949–53	39	14

Age and parity did not appear to be important factors, but the condition was commonest in third to sixth pregnancies

RESPONSE TO TREATMENT

The results are summarised in table IV

Booked Cases—In 67% of primigravidæ and in 60% of multigravidæ, simple measures led to rapid recovery, the remainder required more active treatment, including fluid replacement per rectum or intravenously 2 of the 99 primigravidæ aborted spontaneously, and in 1 the pregnancy was terminated because of the persistence of severe vomiting Of the 144 multigravidæ 1 aborted and in 4 pregnancy was terminated

Emergency Cases—Only 43% of primigravidæ and 34% of multigravidæ responded to simple measures, as in the booked cases, the multigravidæ were more ill and difficult to cure than the primigravidæ

7 of the primigravidæ and 14 of the multigravidæ aborted spontaneously Termination of pregnancy was necessary in 10% of the primigravidæ, and in 20% of the multigravidæ

As table III shows, 11 out of 6221 pregnancies in Aberdeen in 1952–53 were terminated because of hyperemesis, 9 of these were in multiparæ

MATERNAL DEATHS

Of the 453 women admitted to the Aberdeen Maternity Hospital because of hyperemesis in 1938–53, 5 died, but only 2 of the deaths were attributed to hyperemesis, the other 3 being due to difficult labour, pulmonary tuberculosis, and eclampsia

TABLE III—DATA ON ABERDEEN PATIENTS ADMITTED TO HOSPITAL WITH HYPEREMESIS GRAVIDARUM, 1938–53

Year	Total no of deliveries in Aberdeen	Patients admitted with hyperemesis								
		Primigravidæ			Multigravidæ			Total	Rate per 1000 births	Percentage of pregnancies terminated

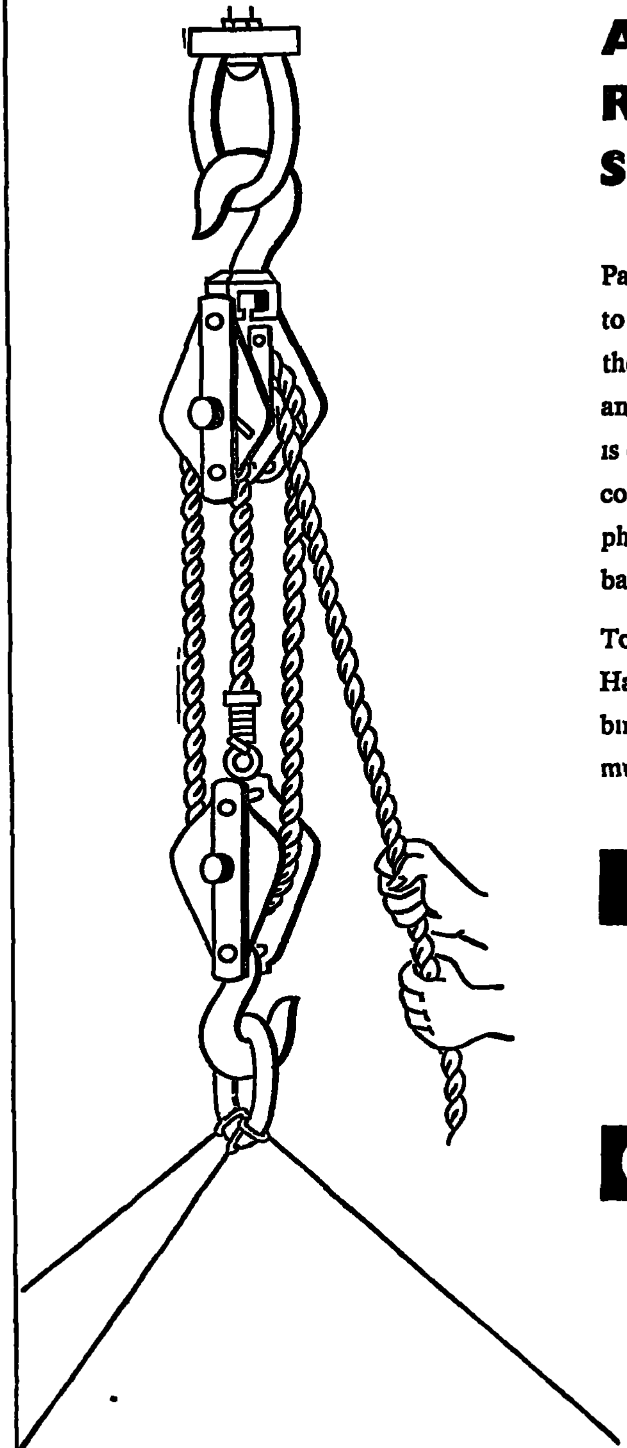
Multigravidæ	150	52 (34 6%)	46	14	34	—	5	64



Avoiding Resistant Strains...

Particular emphasis has been given to the use of combined chemotherapy in the treatment of infections, and it has been realised that there is considerable merit in the judicious combination of antibiotics and sulphonamides in the prevention of bacterial resistance

To aid the Practitioner, Allen & Hanburys have introduced two combinations of drugs known to exhibit mutual reinforcement

SULPENIN

FOR COMBINED ORAL PENICILLIN AND SULPHONAMIDE THERAPY

and

GUANIMYCIN

FOR COMBINED ORAL STREPTOMYCIN AND SULPHAGUANIDINE THERAPY

a chronic infective granuloma, but on careful inspection a thin bluish line or area can often be seen at the periphery, either at the tip of the finger or at the lateral edge of the nail. This characteristic pigmentation is said to be pathognomonic of malignant melanoma (Pack 1952).

Case-records

The first 3 cases were seen at a clinic for infections of the hand.

Case 1.—A housewife, aged 60, first attended the hand clinic in June, 1955. She had suffered from acrosclerosis for many years, and she had had many infections around the nails. About a year ago she had noticed that the right thumb was sore around the tip of the nail, which bled and discharged some pus. This sequence had been repeated at intervals up to about six weeks previously. On this occasion the condition had not subsided, and the thumb had started to swell, bleed freely, and smell unpleasantly.

On examination in the hand clinic, the right thumb distal to the interphalangeal joint was almost replaced by necrotic granulation tissue, most noticeably over the site of the nail bed. Seropurulent fluid oozed from the granulations, which were covered with crusts. The other fingers showed trophic changes at their tips and the nails were stunted and blackened. There were some soft glands in the axilla. Carcinoma of the thumb was provisionally diagnosed and a biopsy specimen was taken. This was reported as showing hyperkeratinisation due to non-specific inflammation with no evidence of malignancy. A further more generous biopsy specimen, however, confirmed the clinical diagnosis of malignant disease, and was reported as a multicentric squamous cell carcinoma grade I–II. The thumb was amputated through the carpometacarpal joint as this was the most distal area free from growth on frozen section. Postoperatively the enlargement of the axillary glands rapidly subsided.

Case 2.—A housewife, aged 76, was seen in the hand clinic in 1948 with a history of a penetrating injury to the dorsum of the web of the first left space one year before; this had never completely healed. A few weeks before it had become painful and she had treated it herself with poultices.

On examination, there was a hard plaque on the dorsum of the first web on the left hand. It was ulcerated with a rolled edge and there was a scab overlying the ulcer; the surrounding tissues were inflamed. Biopsy showed a squamous-cell carcinoma and the lesion was widely excised. When last seen early this year, the patient was well with no sign of recurrence. When referred to the clinic this was an obvious tumour but its early evolution was like that of an infected wound and its chronicity would have suggested a retained foreign body.

Both these cases are typical examples of squamous carcinoma of the fingers. During most stages of the type exemplified by case 1 the lesion may be mistaken for a chronic infection with massive granulomatous changes, and it is important to realise that biopsy may not at first show the true nature of the lesion, partly because of changes due to the overlying chronic infection.

Case 3.—This patient, aged 30, nine months previously had sustained a minor injury to the interphalangeal joint of his right thumb. About a month later he had noticed a small dark blue line at the base of the thumb nail. The line had slowly extended to the distal end of the nail, and the nail had begun to thicken and split until a V-shaped cleft had formed in the nail through which "flesh" began to protrude. The thumb had become painful for the first time. Three months previously he had been referred to another hospital where chronic infection of the nail bed had been diagnosed and the nail removed.

On examination in the hand clinic the nail and nail bed of the right thumb were almost replaced by "granulation tissue" covered with pus and dried blood with the remains of deformed nail at the side of the mass (see figure). On close inspection there was a faint bluish discoloration at the distal end of the mass. Radiographic examination showed rarefaction of the distal phalanx but no signs of bone erosion, and biopsy confirmed the diagnosis of malignant melanoma. The thumb was disarticulated through the metacarpophalangeal joint. Gland biopsy showed no evidence of malignant deposits.

The next 2 cases were seen in other departments, and in both the initial diagnosis seems to have been chronic infection.

Case 4.—A motor mechanic, aged 53, attended with a history that about five months previously he had sustained an abrasion to his left forefinger which had failed to heal despite local applications.

On examination, there was an ulcer measuring 1 × 1/2 in on the radial side of the left index finger, involving the proximal phalanx. It had a raised edge with red granulations overlying a hard base. There was some slough overlying the granulations; it was mobile on the underlying tissues and painless. Biopsy showed a grade I–II squamous cell carcinoma. The index finger was amputated together with the head of the metacarpal.

Case 5.—This patient was initially treated elsewhere, but was referred to the department of radiotherapy at this hospital. He was a man, aged 62, who had been found to have "eczematous ulceration around the right thumb nail with blackish pigmented patches in the skin around." This had been treated with sulphonamides, penicillin, and immobilisation but it had failed to heal; and three months later the terminal phalanx and the head of the proximal phalanx had been removed; the wound had healed well. Nine months afterwards two small firm subcutaneous nodules had appeared in the skin of the forearm, and biopsy of this lesion had shown a malignant melanoma. Metastases developed rapidly in his axilla, and he died shortly afterwards with multiple secondary deposits.

Discussion

My purpose is to draw attention to primary malignant disease of the fingers presenting as a septic lesion.

The precise incidence of these tumours is difficult to assess. Mason (1937) estimated that 10% of all skin cancers affected the hand, but Clarke (1944) indicated that only 4% did so. Clarke suggested that 5% of all cancers of the upper extremities were on the fingers. Bickel et al. (1943), in a review of 155 melanomas of the extremities, found that 6.5% arose from the nail beds of the fingers; and Pack et al. (1952) found that 1.3% of his series of 1222 melanomas of all sites arose in this situation.

It is important that these tumours should be diagnosed as soon as possible, since the prognosis, particularly of malignant melanoma, depends directly on the extent of spread of the growth before treatment is begun. Driver and MacVicker (1943), discussing subungual melanoma, estimated that the five-year survival rate was only 2% if lymph nodes were involved at the time of treatment, whereas nearly half the patients with no lymphatic metastases survived longer. The prognosis in squamous cell carcinoma of the fingers is excellent if the lesion is treated by excision before metastases occur.

It is clear from published reports that, as in the cases reported here, neoplasms of the fingers are still commonly diagnosed and treated as chronic septic lesions for long periods before their true nature is recognised. It cannot be too strongly emphasised that if a chronic lesion of a

Hormones and Breast Cancer

ALTHOUGH the endocrine control of mammary cancer was attempted, with initial success, sixty years ago, this method of treatment has yet to be widely used Increasingly radical surgery and more intense radiation have been urgently pursued for decades, with little improvement in survival rates and often only questionable benefit to the patient Yet these measures are still the only relief offered to the great majority of women with breast cancer

Increasing knowledge of the factors affecting the growth of mammary tumours, and the evolution of endocrinology, have gone hand in hand, so that today the clinician has a large volume of experimental fact on which he can draw It has been shown that many breast tumours depend for their maintenance and continued growth on those hormonal factors which control the growth of normal breast epithelium The maturation and rupture of the ovarian follicle, with its waxing and waning secretion of the steroid hormones œstrogen and progesterone, follows a similar rhythmic rise and fall in the secretion of the pituitary gonadotrophins Thus, removal of the ovaries destroys the synergistic action of the pituitary and ovarian hormones responsible for the stimulation of breast growth and consequently causes regression of mammary tumours which are dependent on these mechanisms As the original work of Woolley [1] demonstrated, the adrenal cortex can secrete steroid ovarian hormones after ovariectomy and can thus make up for their deficiency in the stimulation of breast growth It was this work which prompted the courageous and effective technique, introduced by Huggins and Bergenstal,[2] of total adrenalectomy with or following ovariectomy, this operation once more removed the stimulus to malignant breast growth and produced rapid though temporary regression of symptoms in about half the patients with advanced metastases This treatment was successfully adopted in this country, notably by Cade [3] and Pyrah and Smiddy [4] But the operative mortality is appreciable, and by no means all patients are relieved of symptoms for long enough to justify the operation It remains to decide whether it should be reserved for patients in an advanced stage of the disease Despite the removal in this way of the only glands known to produce steroid hormones, œstrogens can still be excreted in the urine,[5] and this activity sometimes persists even after hypophysectomy There is as yet no adequate evidence to show whether or not adrenal rests, normally encountered on occasion along the line of the urogenital tract, are responsible for this activity, but failing such an explanation it seems that an additional source of steroid hormones must be sought

Another approach to abolition of circulating steroid hormones is hypophysectomy, which will deprive the target organs (the ovaries and adrenals) of the essential trophins secreted by the pituitary [6] This operation has the virtue of removing at the same time pituitary secretions such as mammatrophin (prolactin) and somatotrophin (growth hormone), which are important factors in breast development and secretion [7] According to Russell's [8] recent report, division of the pituitary stalk—a less severe operation than complete hypophysectomy—produces almost total loss of pituitary secretion by cutting off the blood supply and causing selective necrosis of the anterior pituitary This operation might well be substituted for the more severe one Another alternative is irradiation of the pituitary Forrest et al [9] implanted radon seeds into the pituitary fossa by means of a cannula passed through the nostril and sphenoidal sinus, but damage *to the optic tract was a serious complication in* 4 out of their 33 cases Other techniques of irradiation are being investigated which may reduce the risks of blindness In his communication on p 671 Mr Davies describes a method of injecting radioactive fluid into the pituitary fossa But irradiation does not with certainty destroy all the endocrine cells, and methods which achieve this aim will be more effective

Other hormonal factors are certainly of fundamental importance in the growth of breast cancer and it is possible that what are now regarded as autonomous tumours may in fact be dependent on secretions as yet unidentified One known hormone stimulating breast growth, however, is mammatrophin or prolactin Much less is known about it than about steroid hormones, but it is encouraging to know that a method has been developed for the estimation of this substance in urine,[5] and that it is being applied to the investigation of the hormonal status of cancer patients So much concerning these mechanisms is still unknown that we may be guilty of neglecting what we do know Certainly this seems *to be* the case so far as the relation of the thyroid gland to breast growth is concerned It has been suggested by Loeser [10 11] for many years that hypothyroidism is conducive to and aggravates breast cancer, and there *is some statistical evidence* to support this Experimentally, it is known that thyroid deficiency sometimes permits a more florid growth of the breast,[12] and there is fragmentary evidence [13] that pituitary adenomas consequent on thyroid deficiency can cause increased stimulation of breast growth It seems that the simple trial of thyroid administration to women with breast tumours would be easy, cheap, not obnoxious to the patient, and possibly beneficial

While the endocrinological approach offers hope that the fundamental mechanisms of mammary carcinogenesis may finally be unravelled, *it is* obvious from clinical experience and from the detailed observations of Foulds [14] that "progression" to an autonomous state takes place in breast cancer To interfere with hormonal mechanisms in the ways we are *doing today seems to halt tumour* growth and spread for a time only If treatment was advised before the patient's condition had seriously deteriorated and before the tumour had "progressed" to a considerable degree of autonomy, then the delay to further spread might at least be longer Before autonomy is completely established, however, the lot of the patient can be improved, and, as Dr Foss shows in his article

After adrenalectomy the average free acid curve remained near the lower limit of normal throughout the test The mean highest concentration after giving gruel was 25 units, which is significantly lower than that before operation (t = 2 32, D F = 13, P = <0 05) In the 4 cases in which preoperative and postoperative tests were made there was a considerable reduction in the concentration of acid after adrenalectomy The acidity of the resting juice was not altered significantly

Correlation between Gastric and Adrenocortical Secretions

Preliminary investigation showed that the urinary excretion of reducing corticoids was often increased in hyperchlorhydric patients (table II) For this reason a controlled investigation of the excretion of 17-hydroxycorticoids (which was thought to be a more specific measure of adrenocortical function) in relation to gastric secretion was undertaken The highest concentration of acid obtained after giving gruel was plotted against the twenty four hour excretion of 17-hydroxycorticoids (fig 2) Though no significant correlation was found between the two variables, most of the patients who had high 17 hydroxycorticoid excretion (including several without Cushing's syndrome) also had a high concentration of gastric acid On the other hand, a high acid concentration was often associated with normal or zero excretion of 17-hydroxycorticoids

Discussion

It seems clear that the gastric hypersecretion in Cushing's syndrome is caused by an excessive production of steroids by the adrenal cortex, for it is abolished by adrenalectomy, and similar hypersecretion is produced by administering corticotrophin or cortisone Although fatal bleeding from an acute gastric ulcer (Swan and Stephenson 1935) and from an unknown source (Knowlton 1953) has been reported, duodenal ulceration does not appear to have been observed in Cushing's syndrome, and it was not present in our cases This is surprising in view of the gastric hypersecretion and the frequency with which ulceration follows the therapeutic use of pituitary and adrenal hormones

The high level of excretion of reducing corticoid and 17-hydroxycorticoid excretion in some hyperchlorhydric patients suggests that the level of adrenocortical activity may be one factor influencing gastric secretion, even in the absence of overt disease of endocrine glands There

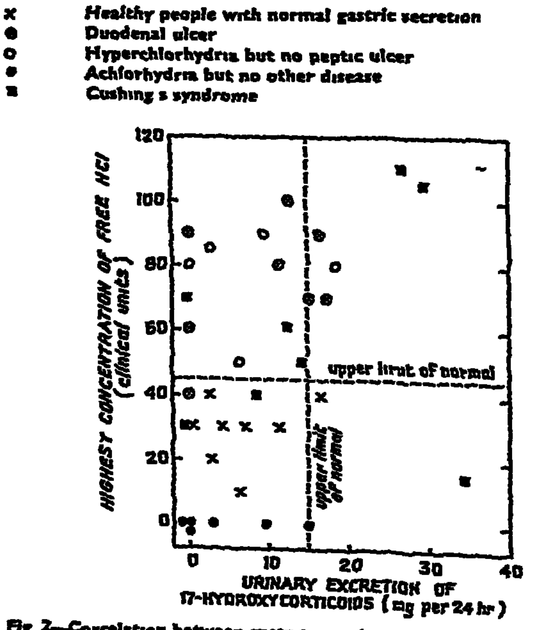

Fig 2—Correlation between gastric secretion and urinary excretion of 17 hydroxycorticoids

Though there is no correlation in general, most of those who had high 17-hydroxycorticoid excretion were hyperchlorhydric home nurses The very mention of these subjects makes it obvious that modern public-health practice cannot be successfully carried out in isolation it requires serious cooperation, not only between the branches of our profession but with a host of outside agencies as well The society's council includes a number of doctors who are not themselves in the public-health service, and its minutes show the great importance it attaches to representation on other bodies, lay and medical, and to joint meetings to discuss matters of common interest Similarly, many of the fellows themselves are making every effort to increase collaboration with their colleagues in the hospitals and in general practice The barriers, indeed, are breaking down at last, and this is one of the most hopeful aspects of post-war public health Let us trust that the years of disappointment are over, and that the Society will prove as adventurous at the beginning of its second century as it was at the beginning of its first

Annotations

SMOKING

ON Monday the Minister of Health was questioned in the House of Commons about the association between tobacco smoking and lung cancer The tenor of his replies (see p 696) was profoundly unsatisfactory He might have used the occasion to state the danger categorically and to undertake to bring this to the notice of the public by other means Instead he refused to initiate a publicity campaign and suggested that "the extent of the problem should be neither minimised nor exaggerated" *Within an hour the tobacco companies* had issued a smoke screen thick enough to obscure even a much plainer statement

If any other poison sold for public consumption were believed to be causing some thousands of deaths each year, its sale would be suppressed One reason why this step has not been taken in the case of tobacco is that any Government initiating such a measure would fall on the morrow as a nation we are tobacco addicted A second reason is that if the Treasury were denied the sum of £707 million a year now being yielded by the tobacco duty our fiscal policy would have to be radically re-shaped There is at present no chance—or, as the smokers among us would put it, no risk—that the sale of tobacco will be controlled

But this does not signify that we should accept the status quo In London nearly all those engaged in investigating the long-term effects of tobacco on health or specialising in the treatment of lung cancer gave up smoking some time ago We must not rest content until the whole community has understood the facts that have led this small group to change their habit Occasional statements in Parliament do not reach, or are not long remembered by, most people In 1954 the then Minister of Health issued a warning[1] which was hardly less explicit than that uttered this week Yet since then we have all often heard well educated people ask whether there "is anything in this tobacco scare" Their ignorance may be due partly to reluctance to learn, but partly without doubt it is due to the mortal unwillingness to accept anything which has not been said again and again

A decision to control the sale of tobacco would be administrative—in other words, political But a decision to impress the hazards on the public may properly be regarded as medical Such a campaign would yield no rapid results heavy smoking bears none of the stigma of heavy drinking, and an exchange of cigarettes is as *much part of the established social* order as an exchange of handclasps But a useful start has already been made For instance, in a recent B B C television programme a doctor set out the facts with admirable objectivity Beyond such individual efforts, the Central Council for Health Education might suitably issue pamphlets for distribution by general practitioners and the British Medical Association might again use the occasion of its annual representative meeting—always closely watched by the lay press—to rehearse the facts If such approaches prove ineffective doctors might band themselves together to bring home the risks to their patients This would be a fine exercise in preventive medicine—and incidentally in public spirit Few patients with bronchial carcinoma could then say they had not been told how this might have been averted

ILEOSTOMY

BETWEEN 1928 and 1952, 871 patients were treated for ulcerative colitis at the Lahey Clinic, 413 (47%) being submitted to surgery, during this period the mortality for the ileostomy fell from 18 to 5% Dr Neil Swinton gave these figures in a discussion by the proctology section of the Royal Society of Medicine on May 2 He dealt more fully with an analysis, by Colcock and Mathiesen, of their more recent cases between 1946 and 1954, 307 patients were submitted to ileostomy and colectomy, including operative and late deaths the mortality was 11% (34)—a figure which closely matched that given by Mr B N Brooke of 12% (15 deaths in 126 patients) Dr Swinton and Mr Brooke agreed that intestinal obstruction was a common sequel, this complication developed after discharge from hospital in 38 of 307 Lahey Clinic patients and in 9 of Mr Brooke's 126 patients

The ileal stoma calls for considerable care at the initial operation, and the technique of its construction is evidently becoming standardised In all centres the importance of fixation of the mesentery in order to avoid ileostomy prolapse or recession is appreciated At the Lahey Clinic, as elsewhere, a separate stab wound is now found to be more satisfactory than the main incision for accommodating the stoma, eversion of the mucosa *and direct suture to skin* is also becoming widely practised Complications such as fistula, prolapse, and recession, which render the stoma inefficient, call for operative revision, a further operation for excision of the whole or part of the bowel provided an opportunity for such revision in 9, and a separate operation was required in 4, of 106 cases in which Mr Brooke did the original ileostomy

The maintenance of electrolyte balance is of vital importance in reducing mortality *after ileostomy* Sodium is lost in direct proportion to the volume output, which may be as much as 3 litres in twenty-four hours shortly after operation, decreasing to 500 ml later, Brooke has found its concentration to be roughly 300 m eq per litre falling to 150 m eq per litre from the *long* established stoma Accordingly sodium requirements can be estimated from the daily volume excreted through the ileostomy

When the stoma is efficient, so *that an* adherent bag may be applied to it, patients express satisfaction with an ileostomy, even five years or more after its institution, and they remain at full and arduous work Nevertheless some maintain that an ileostomy is unnecessary Mr Stanley Aylett has undertaken ileorectal anastomosis in 38 patients, of whom 1 died, he has found that the state of the rectum improves after anastomosis, though healing, judged histologically, is not perfect This finding is supported by the *experiences of* Mr Lawrence Abel and Mr A Dickson Wright A sharp division of opinion

COMMENT

We suggest that in this patient the association between he spinal anæsthetic and the subsequent paralysis is rrefutable. A latent period of seven days before the nset of symptoms is not uncommon, and it distinguishes his type of injury from that following direct damage to he spinal cord. The progression of the disease is due to radual constriction of the cord by the extension of ibrous adhesions, and consequent impairment of the lood supply. An erroneous tentative diagnosis of pinal tumour, followed by laminectomy which establishes the correct diagnosis is a common sequence in cases of adhesive arachnoiditis.

Discussion

Adhesive arachnoiditis is not confined to patients who have had spinal anæsthesia.

As long ago as 1909 Sir Victor Horsley reported a series of 21 patients in whom the gradual onset of weakness in one leg was ultimately followed by paraplegia. Adhesive arachnoiditis was diagnosed usually at laminectomy, because the clinical features were indistinguishable from those of spinal-cord tumour. Characteristically there were dense adhesions obliterating the subarachnoid space in the mid dorsal region and extending caudally. The spinal cord looked shrunken, and in many cases it was compressed by cystic accumulations of C.S.F. In addition, there was often evidence of ischæmic changes in the cord substance.

In 1936 Elkington published a review of 41 cases with similar symptoms and signs. He admitted that the cause of the adhesive arachnoiditis was obscure but suggested that trauma, infection, or syphilis could be responsible. In 18 patients, however, he was unable to show any cause. Elkington emphasised that the essential change was the formation of adhesions and cysts in the subarachnoid space, and he drew attention to the poor prognosis in patients with secondary ischæmic changes in the spinal cord.

Adhesive Arachnoiditis Following Infection

More recently Turner (1948) has shown that diffuse adhesive arachnoiditis may complicate cerebrospinal meningitis either during the acute phase or in the convalescent period. Of the 13 cases described, bacteriological evidence of meningococcal infection was obtained in 9, but in the remainder the diagnosis was based on clinical evidence.

The single case reported by Barker and Ford (1937) is interesting in that the arachnoiditis complicated acute benign lymphocytic meningitis. Improvement followed laminectomy, but after an attack of influenza the patient again became paraplegic.

Attention was first drawn to the relation between virus infections and adhesive arachnoiditis by Horsley (1909), who described paraplegia following an attack of herpes. Many years later Brook et al. (1936) reported 3 cases of paraparesis after spinal anæsthesia and suggested then that the paraparesis was caused by a virus infection superimposed on the effects of spinal anæsthesia. The suggestion that a subclinical virus infection might precipitate adhesive arachnoiditis after spinal anæsthesia was again made by Terp (1950) when describing 5 cases; in 4 the anæsthetic had been a 1/1500 "light" solution of cinchocaine hydrochloride and in the 5th a 1/200 solution of 'heavy' cinchocaine hydrochloride. Thorough investigation failed to establish the cause of the arachnoiditis, but Terp pointed out that, although his technique had been the same for many years, all the cases occurred within a period of six months. Such a grouping certainly suggests an infection with a long incubation period, and in the absence of positive evidence a virus infection would appear most likely.

Adhesive Arachnoiditis Following Spinal Anæsthesia

After the administration, in the same operating-list, of a 1/1500 "light" solution of cinchocaine hydrochloride to 2 patients who later became paralysed, judgment was given in the High Court that this complication resulted from contamination of the anæsthetic by phenol (*Times* 1953). It was postulated that contamination was caused by the permeation of phenol through minute cracks in the anæsthetic ampoules. This judgment was far from generally accepted by anæsthetists; a subclinical virus infection seems as likely a cause of the complication as phenol contamination. It is, of course, possible that the damage was caused by the anæsthetic alone—an explanation for which there is considerable clinical and experimental evidence.

Davis et al. (1931) gave clinical doses of cinchocaine and procaine intrathecally to dogs, in which unequivocal pathological changes in the subarachnoid space developed; the most constant change was a meningeal reaction, which was found in every animal. The inflammatory response was accompanied by thickening of the arachnoid membrane, which contained collections of proliferated arachnoidal cells.

Further investigation by Lundy et al. (1933) established that procaine has a direct toxic effect on the spinal cord of cats and that the concentration of the drug is as important as the total quantity administered.

Lundy's work was confirmed by MacDonald and Watkins (1937), who, also working with cats, obtained conclusive proof that the incidence of paralysis after spinal anæsthesia by procaine was related to the concentration of procaine introduced into the theca. They pointed out that in the cat the bulk of spinal nervous tissue was large in relation to the space within the bony canal and that therefore the volume of fluid available for diluting the anæsthetic was small. They suggested that in man paralysis was usually avoided because of the rapid dilution of the anæsthetic by C.S.F.

"*Light*" *cinchocaine anæsthesia.*—Clinically, since the publication of Hewer's account (1933) of adhesive arachnoiditis after the use of "light" cinchocaine, many similar cases have been reported. In particular Thorsen (1947) investigated the complications of spinal anæsthesia in a series of 2493 cases. 1749 of the patients were given procaine, and in none of these did adhesive arachnoiditis develop; but among the 744 patients to whom "light" cinchocaine was administered arachnoiditis developed in no less than 6. The likelihood of "light" cinchocaine anæsthesia being followed by arachnoiditis is also shown by Terp's (1950) report, already mentioned.

The most likely explanation for the increased risk of injury from "light" cinchocaine is probably related to the volume used. When 10–20 ml. of anæsthetic solution is injected into the spinal theca, there is considerable risk of displacement of C.S.F., so that the membranes and cord, particularly in the immediate vicinity of the injection, are bathed in a solution which remains relatively undiluted.

Continuous spinal anæsthesia.—A further group of patients in whom adhesive arachnoiditis is particularly liable to develop are those exposed to continuous spinal anæsthesia. This involves continuous or repeated injections of small quantities of the anæsthetic, so that a limited area of the spinal cord and meninges tends to be in prolonged contact with the potentially noxious solution.

Kennedy et al. (1950) reported 12 cases of severe spinal-cord paralysis caused by spinal anæsthesia, including 5 cases of adhesive arachnoiditis following continuous spinal anæsthesia. A year later Woods and Franklin (1951) reported progressive spastic paraplegia in a patient who had had continuous spinal anæsthesia, and who died from pulmonary embolism four days after laminectomy.

At necropsy adhesive arachnoiditis was found; the pathological changes were confined to that portion of the cord and meninges which had been in contact with the anæsthetic. It was concluded that the cause of the spastic paraplegia apparatus Dr A Lacassagne points to some of the events that took so startling a turn in 1945 when "radiobiology ceased to be a discipline interesting only a small number of experimenters and medical specialists", and finally Dr James T Case, whose radiological experience goes back to 1903, looks briefly at some of the more prominent developments in diagnosis and therapy

From year to year these exciting happenings have been recorded and discussed in the pages of the *British Journal of Radiology*, which has deservedly won a high place in the world's scientific literature We wish it, and its editors and contributors, many more successful jubilees

COLONIAL-SERVICE CANDIDATES FOR THE F R C S

TOWARDS the end of last year Lord Malvern, F R C S, Prime Minister of the Federation of Rhodesia and Nyasaland, discussed with Sir Harry Platt, P R C S, the position of candidates from the Colonial Medical Service for the final examination for the F R C S Lord Malvern pointed out that the new regulations require a candidate to complete two years' appointments in recognised hospitals, including six months' service as casualty officer These regulations virtually preclude any doctor in the Colonial Medical Service from taking the fellowship unless he happens to have worked in recognised hospitals before joining the service

Subsequently the council of the college agreed that candidates from the Colonial Medical Services who can show that their experience has been at least equivalent to that obtained in two years at recognised hospitals shall be regarded as special cases In a letter to Lord Malvern, the President suggested that candidates who wish to be considered in this way should provide a brief description of the number and types of surgical patients dealt with by them, together with special references to operative experience and opportunities for close liaison with the hospital pathological department, and that each application be supported by the medical director of the territory Such candidates will be eligible to apply for examination after two years, but, said the President, in many cases no doubt they will need longer surgical experience

The discussions and correspondence are to be set out more fully in the Central African Journal of Medicine

SICKNESS AFTER ANÆSTHESIA

SICKNESS after a general anæsthetic is still common enough to leave quite a lot of patients with unpleasant memories of their operation Knapp and Beecher[1] have described some interesting investigations into this problem, and they have studied the value of certain anti-emetic drugs in a series of patients over 15 years of age who underwent practically every type of operation

They first differentiated between nausea, retching, and vomiting Nausea they defined as a subjective sensation of the desire to vomit but without any attempt at expulsive movements It is often accompanied by such objective symptoms as the secretion of saliva, sweating, an increase in the pulse rate, and variation in the rate, depth, and regularity of respiration, so that some attempt can be made to measure its severity Retching and vomiting, both active expulsive mechanisms, are differentiated by the results vomiting always produces some gastric contents, retching produces nothing, and they can be graded according to the number of times they take place and the duration of the episode

In Knapp and Beecher's series the sequence of anæsthesia was invariably nitrous oxide, oxygen, and ether, and it was chosen because it seemed likely to lead to more post anæsthetic sickness of all types than any other combination of agents, and it would therefore provide a reasonable trial for the three anti emetics These were dimenhydrinate ('Dramamine'), chlorpromazine ('Largactil'), and pentobarbitone sodium ('Nembutal') A controlled series of patients was investigated with these agents and with a placebo The problem of the placebo reactor was eliminated by giving each drug intramuscularly to the unconscious patient shortly before the end of the operation, moreover, the observations and their object were not made known to the patients All patients were studied closely and continuously for the first four hours after operation, and all were interviewed at the end of twenty four hours A large proportion were also observed frequently throughout the whole of this period

Knapp and Beecher showed that the incidence of sickness of all types after their chosen anæsthetic sequence was 82% In the placebo group they found that there was no difference in the incidence between the sexes during the first four hours after operation After this initial period, when the greater part of the ether had been exhaled and the patient was returning, or had returned, to consciousness, women had significantly more symptoms than men Age did not affect the issue except that those over 40 seemed to be most helped by an anti-emetic A further interesting result of the placebo studies refuted the widely held view that intraperitoneal operations—and the consequent visceral palpation—increase the incidence and severity of post-operative vomiting There was no evidence from these figures that intraperitoneal operations were more likely to produce complications of this sort than non abdominal operations

Chlorpromazine proved to be an effective anti emetic During the first four hours after operation 50 mg produced a significant reduction in nausea, retching, and vomiting, and this reduction continued for twenty four hours In fact, the 82% incidence fell to 59% This result was matched during the first four hours only by 150 mg of pentobarbitone Dimenhydrinate, in a dose of 100 mg, did not reduce the frequency of these symptoms at any time

There are other important effects, however, besides anti emesis The average awakening time of the patient was prolonged by all three drugs, chlorpromazine extending it by almost an hour But whereas patients were peaceful and sleepy when they awoke after chlorpromazine, they were much confused after pentobarbitone Moreover, all drugs in the doses given caused significant hypotension, chlorpromazine being the worst offender Hypotension appeared about forty-five minutes after giving chlorpromazine and usually persisted for two to four hours, though occasionally it lasted much longer

In establishing the effectiveness of chlorpromazine as an anti-emetic in these circumstances, Knapp and Beecher have given a timely warning that success can be achieved only at a cost In attempts to reduce such a common and unpleasant, rather than dangerous, complication of anæsthesia, the risk of less obvious but potentially more disastrous effects must be borne in mind

---

Surgeon Vice-Admiral Sir SHELDON DUDLEY, K C B, F R C P, F R S, formerly medical director general of the Navy, died on May 6 at the age of 71

We also regret to announce the death on May 7 of Major-General Sir CUTHBERT SPRAWSON, C I E, F R C P, a former director-general of the Indian Medical Service

Prof KNUD FABER of Copenhagen, internationally known for fifty years for his work in gastro enterology died on May 2 at the age of 93

THE INDEX and title-page to Vol II, 1955, which was completed with THE LANCET of Dec 31, is published with our present issue A copy will be sent gratis to subscribers on receipt of a postcard addressed to the Manager of THE LANCET, 7, Adam Street, Adelphi, W C 2 Subscribers who have not already indicated their desire to receive indexes regularly as published should do so now

[1] Knapp, M B Beecher H K *J Amer med Ass* 1956, 160 376

On examination the signs were typical of a hypoglycæmic attack and after the intravenous administration of 50% glucose the patient rapidly became normal physically and mentally.

He later stated that in the past two years he had had intermittent blackouts, which were increasing in frequency. The episodes usually took place before the midday or the evening meal and he related them to being tired or without food for some hours. The premonitory symptoms always included hunger, dizziness, and diplopia. If he felt an attack to be imminent sudden exercise would precipitate it but he found that it could be averted by taking glucose tablets or food. There was nothing relevant in the past or family history.

Investigations

An islet cell tumour of the pancreas was tentatively diagnosed and the patient was admitted for further investigations. *A glucose tolerance test* gave the results shown in fig 1. It was only necessary to continue the test for three hours to demonstrate the hypoglycæmia but usually the recommended duration of the test is six hours. The low fasting blood sugar level, the rapid fall from the peak following the ingestion of 50 g of glucose, and the final low value at the end of three hours suggested that glucose was rapidly removed from the circulation. *Liver-function tests* were normal.

Plasma insulin assay.—the patient was starved on two separate occasions: the first time to produce an attack, to observe any clinical changes immediately before the attack, and to ascertain the period of starvation required for this purpose; and the second time to obtain blood immediately preceding the attack for the plasma insulin assay. On the first occasion the patient was starved for nineteen hours. Towards the end of this time he became restless and was behaving like a mischievous child. Suddenly he became violent, shouting and screaming, and it required three men to restrain him. The clinical signs were again typical of a hypoglycæmic attack which responded immediately to intravenous glucose. The blood-sugar level was 53 mg per 100 ml while the attack was taking place. The second time the test was made the blood-sugar level was estimated at intervals (fig 2). When the patient showed signs of an impending attack blood was taken for the plasma insulin assay. An impending fit was diagnosed by comparison with the previous test in which the duration of starvation and the premonitory symptoms and signs had been noted. The plasma insulin assay, made by Dr J Vallance Owen and his colleagues at the Hammersmith Hospital, showed that there were 300 micro units per ml. compared with the normal value of 31–82 micro units per ml. On this result an islet-cell tumour of the pancreas was firmly diagnosed.

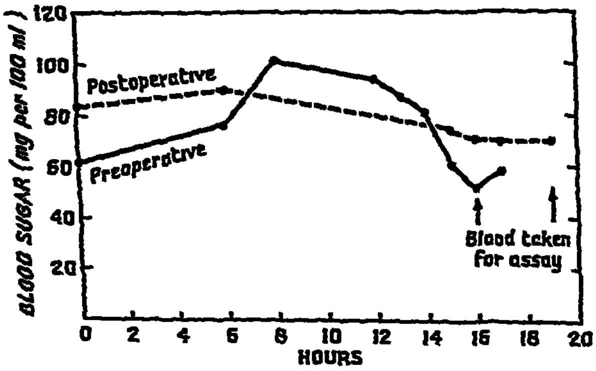

Fig 2—Plasma insulin assay

Operation

The pancreas was explored by Mr Norman Tanner on April 21, 1955. A pink tumour 2 cm in diameter was found near the surface of the pancreas and 5 cm from the tail. It was attached on its deep surface to the underlying pancreatic tissue but was easily enucleated. The remainder of the pancreas and other likely sites of ectopic pancreatic tissue were palpated but no further tumours were found; the liver and other abdominal viscera appeared normal on palpation.

Histological Report (Dr G T Allen)

A section (fig 3) showed an encapsulated tumour with a collagenous matrix in which lay scattered irregular masses of islet tissue and ducts. The more compact areas of islet tissue were recognisable as such but many areas were in the form of strands of irregular islands. Specific stains for granules failed. In view of the encapsulation of the tumour and in spite of the irregularities of the islet tissue, this was reported as a benign tumour. Another section (fig 4) showed easily recognisable islet tissue near the capsule. Some of the histological features of this tumour suggested a mixed tumour of a fibro adenomatous type rather than a pure islet cell tumour more commonly seen in the substance of the gland. All the sections presented the difficulty of deciding the benign or malignant nature histologically, of some of these tumours.

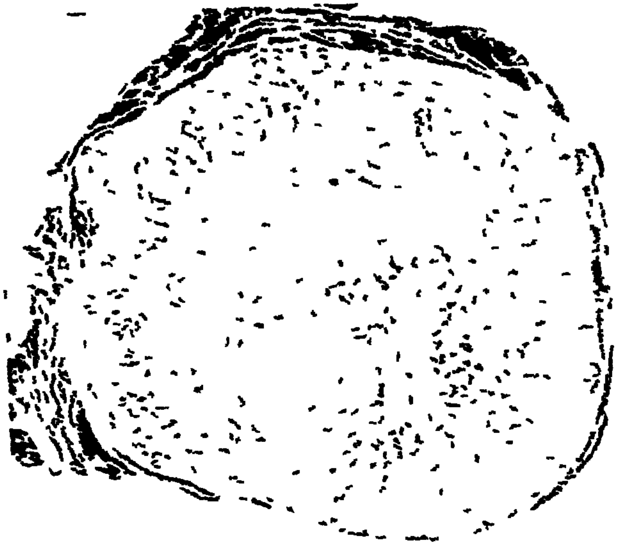

Fig 3—Section of islet-cell tumour

Postoperative Course

Next day the fasting blood sugar level was 136 mg per 100 ml, and on two further occasions the levels were 116 mg and 104 mg per 100 ml. *The starvation test* and plasma insulin assay were repeated but no symptoms or signs of hypoglycæmia appeared in nineteen hours. The results of blood sugar estimations throughout the test are shown in fig 2. On comparing the preoperative and postoperative results it will be seen that the blood sugar level remained more constant after removal of the tumour. The plasma-insulin level at the end of nineteen hours was 50 micro units per ml.

Discussion

These cases nearly always present as attacks of spontaneous hypoglycæmia the causes of which are numerous. Those of clinical significance in adults are functional hypoglycæmia, islet-cell tumours of the pancreas, disease of the liver, and endocrine disorders of the pituitary, thyroid, and adrenal glands.

The first two conditions are the most important and although clinically they are distinguishable, plasma-

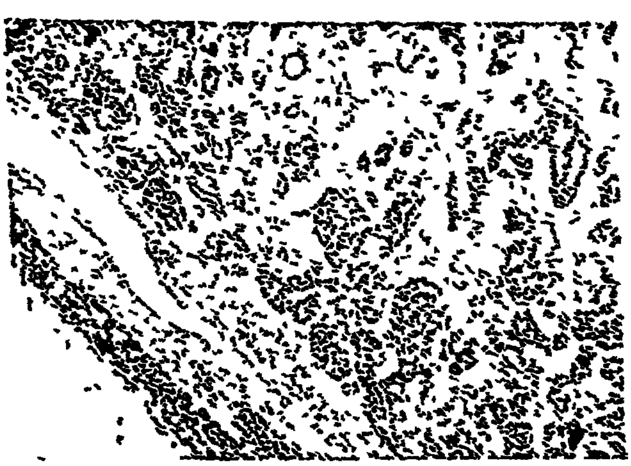

Fig 4—Section showing islet tissue near capsule

we might not even agree on what constitutes good midwifery In midwifery, as so often in medicine, we are faced with a dilemma—are we going to trust the natural processes most of the time, or are we going to try to improve on them? If we follow the first course, we shall leave much midwifery in the hands of midwives if the latter, then we shall get more medical interference, higher episiotomy and forceps rates in primiparæ, and perhaps rather more cæsarean sections

To allow or insist that the woman largely works out her own salvation may be a reasonable attitude, but as a consultant I cannot get out of my mind the innumerable labour difficulties—some trifling, some serious—that crop up from time to time quite unexpectedly Indeed, it may be true that normal midwifery only exists in retrospect, and that a normal case can be diagnosed as such only after the various stages of labour have been completed and the patient has completely recovered Perhaps the young lady was right when, to the question "with whom would you like to be wrecked on a desert island" she replied "an obstetrician" She may have been voicing the opinion of the public, who are making a great demand on hospital confinement and specialist care, because "they know it is safer"[5]

The proportion of live births in England and Wales which took place in institutions, rose from 15% in 1927 to 65% in 1953, though the rise by 11% between 1946 and 1953 was due to a fall in the number of births rather than an increase in the number of institutional beds

Home Confinement

Regional Variations

There are wide regional variations in the proportion of home and hospital births In Southport 90% of births take place in hospital, in London the figure is said to be approaching 80%, in some places it is as low as 30% It would thus appear that with 60% we in Sheffield hold an intermediate position Parallel with this rise in institutional births there was the striking fall in maternal mortality, largely due to other factors, but possibly in part at least related

Essential Requirements

Home confinement can without doubt be very safe, but it presupposes that those in charge of the patient know enough about midwifery to recognise and treat danger in good time We can diagnose only those conditions whose names are in our minds, so we must first be familiar with the possible sources of danger The high head at term may just be a manifestation of parity, but it may also be a sign of placenta prævia—long before there has been any hæmorrhage—or a pelvic tumour, or a brow presentation, or a hydrocephalic head, or a full-term ectopic pregnancy, or some combination of these abnormalities, just to mention a few One must have the right thoughts

> Some years ago a senior resident in a maternity hospital was asked on the telephone to take in a midwifery case He was rather short of beds and thought he ought to ask the general practitioner some questions He learned that the patient was in mountainous labour, but some of the other replies were so equivocal that finally, in desperation, he asked just what was presenting, was it a vertex? "Oh, no," came the reply, "nothing abnormal like that"

But even with the right thoughts, a correct diagnosis is still unlikely to be made without the appropriate clinical examination We who work in hospital still have to admit far too many patients who have not had what I would call proper care

Abnormal midwifery is difficult, even for those with much experience therefore all who want to practise it should have enough experience to become reasonably competent, and should be willing to learn But who has this experience, and how is it to be maintained? For the trend towards institutional births has redu the number of home confinements with the result th general practitioners and midwives are now compet for fewer and fewer cases Besides this being a po it source of friction, it seriously restricts the opportun a practitioner gets of keeping in touch with the subject and tends to make him a less and less suitable person f doing any midwifery at all

Dr S Wand[6] reports that he has recently "led a dep tion to a Committee of one of the Regional Hospital Boa in an area where the amount of hospital midwifery was 83 and the local doctors were complaining that they were n getting enough obstetrical experience" In Sheffield we ar not as bad as this Taking 1953 as a representative yea of the 175 doctors on the obstetric list 136 provided a com plete maternity service for one or more patients, and 3 (25%) of these did so for twenty one or more cases Th experience of 63 doctors not on the obstetric list is that l provided full obstetric service for one or more patient, *but of these only one did so for ten or more cases*

Review of a Sample of Sheffield Births

Early last year I decided to try to find out just wh was happening in Sheffield, and to this end I reviewed the records of every twelfth birth notified in 1953 (th equivalent of one month's cases)

About 30 cases were delivered privately at home o in nursing-homes, and I have no record of a further 2 Of the remaining 600, 310 (51%) were booked for hos pital, the rest being equally divided between those booking a doctor in the first instance, and those bookin the maternity services of the local authority

Welfare Cases

From this sample, we know that of the 161 women booked for home confinement by the maternity service of the local authority, 73 wanted a hospital bed, and from this we may estimate that during the whole year about 850 of this group would have preferred to be delivered in hospital Some of them would not take "no" for an answer, and were eventually admitted

We may look more closely at this sample Their parity and age distribution are given in table I

TABLE I—PARITY AND AGE DISTRIBUTION OF 161 WELFARE CASES IN THE 1953 SHEFFIELD SAMPLE

Parity					
No of patients	35	53	35	21	17
No of pregnancies	1	2	3	4	5 or more
Age					
No of patients	8	93	34	21	4
Age	10–19	20–29	30–34	35–39	40–

There was no age record in 1 case

In regard to their past obstetric history, there were 1 who had had one or more abortions previously, 8 who had had an abnormal pregnancy or labour, and 10 who had had a previous stillbirth or neonatal death O paper, at least, it looks as though some of these women would have been better booked for hospital confinement, and I believe that, except for the few who did not take the clinic doctor's advice and insisted on staying at home, such an arrangement would have been made if a bed had been available

The reasons why some were finally delivered in hosp varied 24 developed some pregnancy or labour complicatio 2 got in because their husbands objected to the arrangements, 1 moved to a house where there was a case of op pulmonary tuberculosis, 1 chose a private nursing home 2 eventually were persuaded to come in because of grand-multiparity and previous stillbirth, and 1 successfully solicited the support of her Member of Parliament

The question may therefore be asked "Are these arrangements satisfactory?" Certainly 73 women in this sample were dissatisfied and some exerted great

Preliminary Communications

ABLATION OF THE PITUITARY GLAND FOR SECONDARY CANCER

In 1955 Rothenberg et al[1] described the treatment of certain forms of secondary cancer by destroying the pituitary gland by injecting radioactive substances Technically this procedure is not difficult, but, since many of the patients are in poor general condition and there may be secondary deposits in the skull and/or the scalp, it is essential that the operation should be as simple and safe as possible

The risk of introducing infection by intranasal injection and the added accuracy obtainable by exposure of the pituitary gland encouraged us to persevere with the ntracranial approach

It is necessary to ensure that the volume of fluid injected is small but contains optimal radioactivity Too little radioactivity would be ineffective in destroying the gland, too much would damage the neighbouring vital parts of the brain, and too large a volume of fluid might burst through the diaphragma sellæ and spill over on to the surrounding structures A needle is used with a bore just large enough for the radioactive substance to flow through easily

A sucker attachment is essential to prevent any contamination of the surrounding brain by any radioactive material that might escape from the sella or from the needle after injection

---

[1] Rothenberg, S F Jaffe, H L, Putnam T J Simkin B *Arch Neurol Psychiat, Chicago* 1955 73 193

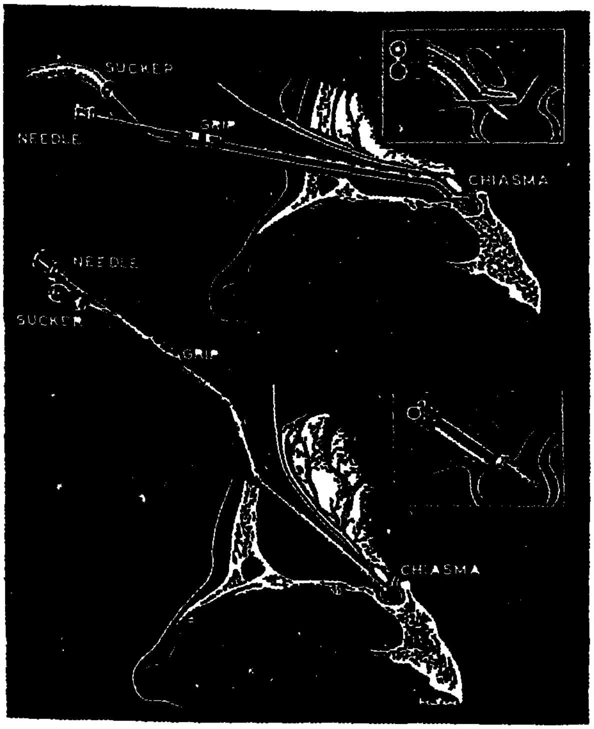

Fig 1—Injection of radioactive fluid into pituitary gland *upper register*, usual approach from just above right orbital margin, *lower register*, ordinary transfrontal approach

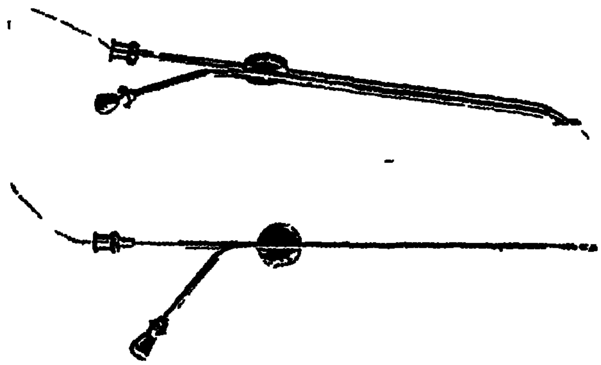

Fig 2—Needle for usual approach from just above right orbital margin

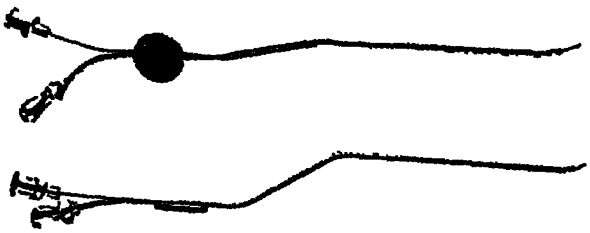

Fig 3—Needle for ordinary transfrontal approach

The usual approach is shown in the upper part of fig 1 Through a small skin flap a trephine hole is made just above the right orbital margin and overlapping the midline by about 0 5 cm The dura is opened, and the frontal lobe is raised and retracted laterally The combined needle sucker (fig 2) is inserted gently along the floor of the anterior fossa until the needle aperture is over the fossa, the end slipping under the chiasma The sucker tubing is attached, the needle pushed home, and the radioactive fluid injected After a minute or so the needle is withdrawn The sucker is left in situ for a few more minutes

When the frontal sinuses are very large, or when there is any abnormality in the region of the pituitary fossa, the ordinary transfrontal approach to the pituitary gland is used, as shown in the lower part of fig 1 After the bone flap has been raised, the frontal lobe is raised extradurally as far as the sphenoidal ridge and thereafter intradurally The optic nerves and chiasma are exposed, and the needle with sucker attached (fig 3) is inserted through the diaphragma sellæ into the pituitary gland The injection is made into the four quadrants of the gland without completely withdrawing the needle The sucker prevents contamination After a few minutes the needle is withdrawn and a lintine patty is placed over the hole in the diaphragma sellæ for a few minutes, after which it is withdrawn and tested with a geiger counter Leakage is minimal by this technique

The needles are of stainless steel The needle for the usual approach (fig 2) is 15 cm long and projects 0 75 cm beyond the sucker, which is of gauge 15 S W G The needle tube is of gauge 23 S W G When the ordinary transfrontal approach is used the needle (fig 3) is 18 65 cm long, the sucker-needle guide tube is of gauge 13 S W G, and the outside diameter of the needle 15 S W G

My thanks are due to Prof B W Windeyer, Dr J D N Nabarro, Miss M D Snelling, and the late Miss Diana Beck for permission to operate on their cases, to Dr A M Jelliffe, who is collaborating with me in this work, Mr R A Millard and his colleagues of the instrument department of the Middlesex Hospital, for the needles, Miss E Hewland, medical artist of the hospital, for the drawings, and Mr M Turney for the photographs

Midwives' Board It would make it possible to train an aristocracy of general practitioners, such as Mr Arnold Walker, chairman of the C M B, has advocated [9]

Dabbling in midwifery must be discouraged, in much the same way as dabbling in surgery is discouraged, and in fact this is the implication of the general-practitioner obstetric list I would like to push out of domiciliary midwifery those who are afraid of it, for they have no courage, and those who are not afraid of it, for they have no imagination, those who say there is nothing to it, and are prepared to go and do a case now and then, just to keep their hand in, for they have no understanding, and those who have no interest—for they have no soul

A prerequisite of a good maternity service is the proper training and selection of doctors, and this training and selection must be in the hands of those with experience of the frightful effects of bad midwifery

Of course every general practitioner, unless he has had a six-month training in hospital, must make a start somewhere, and I believe that once he is on the Medical Register he should continue to have the right to practise midwifery This right, however, should be subject to the proviso that he should not be allowed to attend the delivery in the home where conditions may try even the most experienced man Let our beginner make his beginning in some institution where he will be under the eye and control of more experienced colleagues, and let him graduate to home confinement when he has proved his worth Similar rules might very well apply to the midwives In the maternity home too, the doctors and midwives can pool their experience and knowledge, and both be the wiser for it

Education in Midwifery

Whether or not my view is accepted, and we are to move towards more institutional beds and an aristocracy of general practitioners, matters of medical education arise with which I am very intimately concerned

Every doctor runs the risk of meeting the unexpected, and we must therefore give the student a good grounding in the anatomy, physiology, and pathology of parturition We must also teach him how to deal with emergencies—but in no way encourage him to think that without post graduate training he will be competent to practise midwifery except in an emergency Teaching in regard to home confinement is now very limited in Sheffield, because for many years the district of our teaching hospital has been so small This may not be altogether a bad thing, and I have not thought fit to try to change matters The pattern of obstetric care is changing more attention is being paid to the education of the expectant mother in motherhood and mothercraft, and—because there are fewer of the abnormalities, such as contracted pelvis and puerperal sepsis, which used to occupy so much of our time—intrapartum care is becoming simpler So far as the general practitioner is concerned there are only a few operative procedures which he should nowadays practise *outside fully* equipped homes or hospitals The episiotomy and its repair, and the repair of perineal tears, low forceps under local anæsthesia, the use of ergometrine for abnormalities of the third stage, are the main treatments required I myself see no reason why students need go into the patient's home to learn these intrapartum techniques

Joint Advisory Committee

I have mentioned some long term objectives The short term policy should be the formation of a local advisory committee for midwifery, where the difficulties and problems that confront us can be ventilated from time to time indeed, it may be argued that this is a pressing matter, for at the moment I know of no way by which representatives of the local authority, the general practitioners, and the board of governors, the regional hospital boards, and the midwives, can be brought together to discuss matters of common interest and responsibility The difficulty of course is to know who is to set up this committee Frankly, I do not think it matters which authority does it, so *long as it is done*

It is to be hoped that the committee to inquire into the maternity services recently set up by the Ministry of Health will give this and related matters full consideration

Conclusion

A review of the present position in regard to home confinement in Sheffield suggests that extra beds should be made available for those women who desire institutional care and for those unsuitable for home delivery There are, according to my estimate, about 1000 of them, and if they were all delivered in hospital instead of at home as at present then the proportion of hospital confinements in Sheffield would be about 70%—a figure which happens to correspond with that advised by the Royal College of Obstetricians and Gynæcologists in it Report on a National Maternity Service (May 1944) A *close study of a random sample* of those women delivered in Sheffield in 1953 suggests that those seeking hospital beds attend earlier for their antenatal care than those making other arrangements The present divided responsibility for maternal care is underlined, and a plea is put forward for the formation of local advisory committees

I wish to thank our medical officer of health, Dr L Roberts, and his staff for facilities put at my disposal, Dr A K Black, senior assistant maternity and child welfare officer, who very willingly spent many hours going over case records with me, and Mr J H Cargill, clerk of the executive council for Sheffield, for information I also acknowledge help from Mr T E Durrant, my technician at the time, for work in connection with filling in, punching, and counting the punch cards used in this survey

SENIOR MEDICAL OFFICER

MATERNAL AND CHILD WELFARE SERVICE, BRISTOL

WOMAN in her labour ought to be confined in the best possible place and under the best possible conditions At present there are two opinions as to where these are to be found On the one hand there are those who think that all confinements should take place in a hospital or institution, on the grounds that, even with the most careful antenatal care, unforeseen complications may arise affecting either the mother or baby On the other hand there are those who claim that for the normal confinement the home and family setting is best for mother and baby and that institutional confinement tends to convert a natural process into a surgical operation The trend throughout Britain is towards hospital delivery, and in Bristol during the past year only a quarter of all deliveries took place at home

The scheme we put forward is one which we consider combines the best features of hospital and home care Moreover, it ensures that those concerned with the welfare of the mother—i e, the family doctor, midwife and, when necessary, the obstetric consultant—will supervise her during her labour Throughout her pregnancy the mother will have been under the care of her own doctor and will have been seen regularly at his own surgery or

Surgery of Peptic Ulcer

OPENING a discussion in the section of surgery on March 13, Mr H. T. Cox said that dissatisfaction with partial gastrectomy—a well-established procedure with a low mortality-rate—mainly centres around its side-effects. Numerous procedures have been devised to reduce or eliminate these, but, if the various gastric operations are not to rotate in popularity, their results must be compared by means of a simple clinical yardstick. In 100 cases of duodenal ulcer treated by gastro-enterostomy plus vagotomy, he found the side-effects markedly less than in 100 cases treated by partial gastrectomy.

Mr IAN M. ORR (Preston) said that in the stimulation of gastric acid secretion two factors play a part—namely, nervous stimuli via the vagus, and hormonal stimulation due to the activity of cells in the pyloric half of the stomach, in the lesser curvature, and in the duodenum and upper jejunum. Hypersecretion does not occur in every peptic-ulcer patient, and in cases of duodenal ulcer the flow of nerve-secreted acid may be normal or low. The general level of the unstimulated night secretion curves was high in more than half of a duodenal-ulcer group, but even among normal people a few have exceptionally high nerve-secreted acid. This suggests that vagotomy is indicated in only a proportion of duodenal-ulcer cases and might do harm if practised indiscriminately; and, as night acid readings may be high in people without ulcers, high readings are not necessarily an indication of the activity of the ulcer. Surgical treatment must take into account not only the hormone-secreting activity and the nervous secretory activity of the patient, but the age, sex, and physical fitness, and the type of ulcer—duodenal, gastric, or anastomotic.

In a series of 734 operations for peptic ulcer, patients with gastric ulcer had Billroth-I gastrectomies, while those with duodenal ulcer had two-thirds gastrectomies of the anterior Finsterer-Lake type, plus vagotomy if the night secretion was unduly high. A small group, mainly elderly women, had *gastro-enterostomies with or without vagotomy*. In the gastrectomy group 2 patients had a two-stage resection because of gross œdema and inflammation of the duodenal ulcer. The mortality-rate for the series was 1·1%, and a follow-up of 210 patients over five years showed that 5 developed anastomotic ulcers after gastrectomy, without vagotomy, for duodenal ulcer. Of those treated by gastrectomy plus vagotomy none have so far developed anastomotic ulcers. In the late results no striking difference is apparent between the various groups, apart from the incidence of stomal ulcer in 2·4% of patients having gastrectomy without vagotomy.

Reviews of Books

Cancer Cells

E. V. COWDRY, director, Wernse Cancer Research Laboratory, Washington University, St Louis. Philadelphia and London: W. B. Saunders. 1955. Pp. 677. 112*s*.

THE author is an individualist, already well known from his *Textbook of Histology* and his *Problems of Ageing*. It is therefore not surprising that in covering a very wide field he lays more emphasis on certain subjects in which he excels. In fact, he says himself that "no single individual can take the place of all the specialists now investigating cancer."

None the less a well considered plan has been followed, "each chapter constituting more or less of a unit, carrying the account a step farther and supplying a basis for what comes next. . . . The order of presentation was changed again and again as the writing progressed in efforts to gain some measure of continuity." For convenience, a clear summary of the contents is given at the end of each chapter.

The first chapter explains the distinction between malignant and benign tumours. The next three chapters describe the properties of malignant cells, including abnormalities of function, multiplication, and spread, and changes in the cytoplasm and nucleus. Then follows a description of the agents capable of bringing about malignant transformations, the theories concerning their actions, and the susceptibility of normal cells to these carcinogens. The latent period and the factors modifying the production of cancers are next discussed. The last 100 pages deal with general data on diagnosis, prevention, and treatment, and with the history and achievement of modern cancer research. The bibliography includes about 3000 references, compiled with great care.

Those concerned with cancer research are all too familiar with the man who "has an idea" about the cause or cure of cancer. No better book could be placed in his hands, for it is an accurate and up-to-date summary of a great deal of the effort which has been made during the past fifty or sixty years in trying to identify the cause and the cure for cancer. Those who seek information on how the malignant cell differs from the normal will find a reasoned account of the present state of knowledge in this field. Those already tackling this problem may find the section devoted to their special field rather superficial, but this is inevitable in a general book on cancer. For those who gibe at the slow progress which has been made in clinical and experimental studies of cancer and who complain that more time is devoted to mice than to men, the reading of this book will be a salutary experience.

Mind and Body

Psychosomatic Pathology. PEDRO L. ENTRALGO, professor of medical history and rector of Madrid University. London: Harvill. 1955. Pp. 150. 12*s*. 6*d*.

THIS erudite but extremely interesting and readable book is both a critique and a historical survey of what is now known as psychosomatic medicine. The main theses which Professor Entralgo puts forward, with skill and persuasiveness, are:

(1) The term "psychosomatic pathology" *has two complementary meanings*. One is literal and superficial: the study of human disease from the point of view of the two aspects which it presents, the psychological and the somatic. The other is derivative and comprehensive: "the scientific consideration of human disease in conformity with the personal conditions of man's psychophysical reality."

(2) Understood in this derivative and inclusive sense, psychosomatic pathology is a relatively new development. Medicine has always been, in one guise or another, "psychosomatic", but the same cannot be said of pathology.

(3) Primitive Christianity first suggested the possibility of a true psychosomatic pathology. "Sin" was distinct from "disease," and this view opened the way to a theoretical and practical consideration of the possible relationships between "moral disorder" and "physical disorder."

(4) "Western" pathology, from the School of Salerno to Freud, has not succeeded in becoming fully psychosomatic. It has been hampered in this respect by its fundamental "naturalism," a continuation of the Hellenic, and by too exclusive an adherence to the "visive" concept of knowledge.

(5) Twentieth-century psychosomatic pathology has regained—in a different form—certain of the possibilities that primitive Christianity offered to the knowledge and practice of the physician, and has revealed the simple underlying reason for the "personalism" of the ancient Semite.

Beginning with the concept of disease in primitive times, Professor Entralgo sketches the beliefs held by two important cultures, the Assyro-Babylonian, in which the sick man was regarded as having sinned, and the Hellenic, in which the disease is considered more as a departure from man's "nature." This led to the naturalism and physiological bias of Greek medicine, which in turn through the teachings of Galen influenced Christian medicine towards physiology. The concept of disease in "occidental" medicine is then discussed, and in his concluding chapter "Towards an anthropological medicine," Professor Entralgo examines the ideas about neurosis before the time of Freud, the work of Freud, and the creation of what he terms "anthropological" medicine, which includes psycho-analysis and psychosomatic medicine in its scope and practice.

The breadth and clarity of Professor Entralgo's survey will stimulate any physician or psychiatrist who is of general practitioners particularly experienced in the work Unfortunately this has not always worked out in practice, and for the most part it is open to any general practitioner to undertake midwifery if he so chooses We should like to see this work restricted to keenly interested practitioner-obstetricians who, though probably with smaller lists, would continue in general work so as to remain in touch with the whole field of general practice Family doctors not doing maternity work should refer their cases to these colleagues A group practice would almost always include at least one practitioner-obstetrician Future entrants to the "obstetric list" would gain their experience and qualify for admission to the list by association with practitioner-obstetricians

Where local-authority medical officers continue in the service they should be given the opportunity to conduct their midwifery practice on the same terms as general practitioners—i e, he, or she, must be able to visit the expectant mother at home where necessary and attend the confinement in this labour-ward unit

In any maternity scheme the needs of the mother and baby are paramount For some years now it has been our experience that mothers approach their confinement with much less fear than formerly This is due, we feel, to over-all antenatal supervision as well as instruction in relaxation We make a point of telling the mother, by discussion, film strips, and diagrams, as much as we think she ought to know about the course of labour and assure her that we will be with her when she needs us All the same there remain the hazards of any normal delivery, and many mothers are aware of these It may be said that "the only normal delivery is the absolutely normal one which has just been completed"

We feel that our scheme would have a wide appeal, for the mother would know that she could be delivered in a place where all the resources of a maternity hospital were readily available should things go wrong, and yet be able to return home immediately for her subsequent care

We should like to record our appreciation to Dr R C Wofinden, medical officer of health, Bristol, for his advice and constructive criticism in the preparation of this article

HOSPITAL FARMS

In his reports[1] on the National Health Service accounts for 1954–55, the *Comptroller and Auditor-General, Sir Frank Tribe*, again refers to hospital farms and market gardens An expert committee reviewed the farming activities of 190 hospitals with 40,000 acres of farmland and nearly 4000 acres of market gardens They found that, in a number of instances, farming had been developed for its own sake, "and the maintenance of pedigree herds and dairy farming had become a major preoccupation with some hospital authorities" In the light of the committee's report, the Ministry of Health advised hospitals that they had no authority to run farms except in so far as they were an essential part of hospital management, and they asked hospitals *to review their farms* By Oct 31, 1955, 207 farms had been surveyed by regional boards Decisions had been reached about the future of 126, and it had been decided that farming should cease at 47 hospitals and be *reduced at a further 38, involving* the disposal of 17,598 acres of land

Trading accounts for hospital farms and gardens in England and Wales in 1954–55 showed an excess of income over *expenditure of £60,000* Farms showed a surplus of £140,000 and market gardens a deficiency of £80 000 (these figures do not include small market gardens) In Scotland farms recorded a net profit of over *£56,000* but *market* gardens showed a loss of just under £10 000

In England Now

A Running Commentary by Peripatetic Correspondents

ART critics have come under the brush at Burlington House this year Sir Alfred Munnings leads the way Besides the usual reliable nags from his stable, he has entered a likely outsider—his witty but good-natured satire on modern art, *Does the Subject Matter?* Of his circle of critics, I got the feeling that Munnings was backing the dog Mr A R Thomson urbanely offers us *The Selection Committee 1955* in an entertaining and elegant crescent before a red curtain But with Mr Richard Eurich the gloves are off and his version of *The Critics* is as harsh as it is accomplished

There is no formal royal portrait of the year, and the place of honour is given to a large study of *The Duke of Wellington* in ducal robes People seemed to be turning with relief from its uncertain grandeurs to the smaller portraits, such as Sir Gerald Kelly's blue and grey picture of *Sir Geoffrey Jefferson, M S, F R S*, who sits at ease looking out sleepily yet shrewdly from beneath heavy lids Though Mr A R Middleton Todd has painted *Lord Adrian, O M, F R S*, in academic robes he too sits at ease before a not too tidy bookcase, looking over his well-known half spectacles In Mr Frederick Elwell's picture, *Mrs Rosemary Adams, F R C S* sits in a draped dress of rich red before a small open desk. Mr Eric Kennington's effective pastel of *Sir Russell Brain, P R C P*, hangs in the select small south room Among the sculpture there is the now almost inevitable head of *The Late Sir Alexander Fleming, F R S*—this time a less familiar one of him in his early 50s—and a bronze of *Dr Roger Bannister*, by Josephina de Vasconcellos Mr Allan G Wyon's silver medallion will later be a suitable prize for meritorious anatomy students at Leeds

Sir Winston Churchill, who has been an honorary R A longer than he has been an honorary F R C S, has two pictures hung, including a dark but attractive interior of *Sir John Lavery's Studio* After-dinner speakers will turn with a shudder from Mr Ruskin Spear's *Unaccustomed as I am* But surely no medical dinner was ever half as horrible as this macabre postprandial occasion

* * *

Now that automation is so much used in anæsthesia, I am occasionally able to contemplate phenomena not directly concerned with the unconscious patient in front of me

I have two long orthopædic sessions each week and here some curious problems have so far eluded solution

A popular method of securing a bloodless field in limbs is to apply an Esmarch's bandage and then to inflate a modified sphygmomanometer cuff, after which the rubber bandage is removed On the pressure gauge of the instrument are two red lines at 250 and 500 mm Hg respectively marked 'arm' and 'leg" Now why use a pressure considerably higher than the systolic blood pressure and why use twice this pressure on the leg? I have posed these queries to two orthopædic surgeons, a physicist, and a hydraulic engineer, and they all gave different answers

I pass over briefly the peculiarities of orthopods as to the time for which tourniquets or their equivalents can be applied One is insistent that I remind him when twenty minutes have elapsed in the case of an arm while his opposite number seems quite annoyed if I venture to remark that an hour has gone by

Even more remarkable is the attitude towards asepsis In the private wing of a London teaching hospital, if a general surgeon drops an instrument it is boiled for ten minutes by the clock and handed back If, however, an orthopædic surgeon does the same thing in the same theatre, twenty minutes elapse At an equally famous London teaching hospital, they boil dropped instruments for two minutes "just to make sure" as their professor of bacteriology has shown that thirty seconds is ample provided that the water in the steriliser does not go off the boil when the instrument is dropped in

It is all very puzzling and I think that in future I must keep my mind on really simple matters of anæsthesia, such as the mode of action of chlorpromazine

Denmark reports only half the mortality (taking the male rate in middle age as *the most reliable indicator*) of Finland, or Canada, or New Zealand [4] At probably a somewhat lower, though still high, level of fat consumption, the Stockholm rate is only half that of Edinburgh, or Aberdeen, or Newcastle, or Cardiff

Our own experience of fat-rationing, starting from 1940 is also adduced in support, but, again, the available data do not fit There was a decline of mortality at the beginning of the war, but the climbing pre-war trend was resumed in 1943,[5] although fat restriction was continued for several years longer and reached its greatest severity (such as it was) in 1947 *If margarine and kindred products are the villains, the story might hang together a bit better*, because, of course substantially more margarine was eaten from early in the war [6,7] In that case, why the decline of mortality in 1940–42 ? The record is anything but straight, and it is good to know that we are soon to have first approximations at least to the facts about E F A consumption in this country during recent years, and not only courageous extrapolations from a few of the figures

The war-time experience of Norway is probably the *most quoted evidence*, *and once again the statistics are* rather different from the common impression of them The actual decline in cardiovascular mortality in Norway is difficult to estimate, and it was salutary to find when I visited there last autumn how much less excited the Norwegian experts were about it than others The fall among men seems indeed to have started *before* food shortages were at all serious [8–10], it was seen in several cause groups, and it affected young persons—i e, non-coronary cases—more than the middle-aged Moreover, it occurred in a period when not only was there restriction of total calories and drastic reduction of fats, but also several *other factors* which *are probably related to the* frequency of ischæmic heart disease were all being influenced in a favourable direction smoking, habitual physical activity, diabetes, *and possibly blood pressure* levels and body weight Those interested might refer to Professor Strom's fascinating account [10] of Norway's war-time increase in infectious diseases, and the decline in dental caries, childhood enlargements of tonsils and adenoids, maternal mortality, stillbirths, infant mortality, various cancers, suicide, and schizophrenia and other psychiatric disorders [11] There almost certainly was some fall in coronary heart disease during the Occupation a reasonable estimate might put it in the order of 20–25% (How unexpected if the substantial increase in the eating of fish and fish products was in some measure responsible But to claim this, or the interference with hydrogenation, as *the* cause in what was so obviously a multifactorial situation, is surely to court the errors of the over simple *tale about fats*) As interesting as this decline is the fact that pre war Norway, although enjoying a high-fat diet, seems to have had rather *low* mortality from coronary heart disease, and after war-time food restrictions were lifted there has again been *a return to relatively low* rates, low at any rate for a " Western " country—little more than half those of Scotland or a third of New Zealand's

I am not suggesting that national death-rates certified to coronary heart-disease should be used in considerations of the ætiology of this condition or, indeed, that they have any value, *and I am well aware that* diverse juggling with the data can yield diverse results I am only making the point that if the data are used at all it should be with greater circumspection In this respect it may be fair to place on record that it was not the vital statisticians, epidemiologists, or social medicine workers in general who first engaged in these exercises, and their hesitation was only partly due to their well known indolence With much experience *of the snares of time* series and international comparison in well tilled fields like infant mortality and tuberculosis their reluctance *was perhaps understandable*

The other principal source of information about the experience of different countries, and at different times is the ad-hoc field survey These, however, are only at their beginnings The difficulties of standardising techniques, population samples, &c, are enormous, for the peoples that need to be studied often differ in such a great many respects Keys himself [12] is pioneering a truly mid century approach to these matters

The second observation I should like to make is that it would help to clarify ideas, and to make communication easier, if there was less premature simplification of the complex of problems into the measurement of serum cholesterol, or β-lipoproteins, and if the term " atherosclerosis " were not used indiscriminately to include anything from experimental fatty lesions in the aorta of rabbits to the whole of the natural history of ischæmic heart-disease in man This widespread contemporary woolliness has had unfortunate results It is a reasonable proposition that several causes and several mechanisms are involved in the human disease, and it is conceivable that some of them are not related in simple fashion to serum-cholesterol, &c But it is a *fallacy to suppose* that this automatically renders them unimportant *The* U K pathological survey which we are now analysing seems to suggest that, in terms of morbid anatomy alone, different factors may operate at different stages in the long journey from flecking of the coronary arteries to the fatal heart disease—age at one stage, " social class " at another, physical activity of work at yet a third, and so on However that may be, the notion of " multiple causes " is crucial for preventive medicine if only because it would be more sensible to propose to the people *that they should modify* their diet *and* other ways of living (should such a programme appear hopeful) than to clamour for a revolution in diet alone Moreover, it may be easier to control the modern " epidemic " of coronary thrombosis than the more ancient coronary atheroma

The main consequence of the prevalent misconception has been the relative neglect of clotting and thrombosis in modern research There are the strongest indications that thrombosis in human coronary arteries should be a major focus of investigation the historical evidence which suggests that coronary atheroma has not increased in recent years, though thrombosis and infarction have the observation which can be made by any pathologist who views his material in epidemiological terms that only a minority of *men* with much or severe coronary atheroma suffer infarction, at any rate in middle age (and also that some with little atheroma can have serious obstruction and ischæmic heart disease), the *precipitate nature of such decline as did in fact* occur in war time Norway, and the striking fall in thrombosis—embolism observed in their hospitals during those years [14], Duguid and related work, and the difficulty of inducing thrombosis and infarction on the experimental atheroma of

LONDON SATURDAY, MAY 12 1956

The Maternity Services

We welcome the announcement that, following a recommendation in the Guillebaud report, a committee has been set up to inquire into the maternity services.[1] The lack of unity in maternity work under the National Health Service has been much criticised, for it has led to duplication and confusion. It is not uncommon to hear of patients attending in the same week a hospital antenatal clinic, a local-authority clinic, and her own doctor. More serious are misunderstandings whereby patients receive little or no antenatal care because each authority thinks that this being provided by another. In some areas coördination has been achieved by advisory obstetric committees which include representatives of the various bodies concerned. The Royal College of Obstetricians and Gynæcologists[2] has recommended unified control at national, regional, and area levels, and on a later page of this issue Professor **Scott Russell** emphasises the urgency of the need for coördination.

Further problems will be before the new committee. Of these perhaps the most important are the place of the confinement and the personnel who should man the obstetric services. The picture of the family doctor and trusted friend bringing the son and heir into the world in the patient's own home is attractive but hardly realistic today. The factors that have caused the trend towards confinement in hospital are well known, and it seems likely that both the wishes of the community and the greater safety for the mother in hospital will cause this trend to continue. But the hospital is not necessarily the safest place for the newborn: the risk of cross-infection by resistant strains of staphylococci is a factor strongly in favour of the type of scheme suggested in this issue by Dr **Sluglett** and Dr **Walker**. They propose that normal cases be delivered by the family doctor and domiciliary midwife in a simple labour-room attached to a maternity hospital and not in the patient's own home. The patient and her baby would be taken home by the midwife within a few hours after delivery. Such a scheme might be extended to include the earlier discharge from hospital of those at present booked for institutional confinement. It has been suggested that if all patients fit for discharge went home on the seventh day, existing maternity beds would suffice for the delivery in hospital of all women who need or desire this. On the other hand, during these seven days babies would run the risk of infection, and it might prove wiser to discharge such patients twenty-four hours after delivery, once careful observation had shown that the condition of mother and baby was satisfactory, before transfer to a lying-in ward. When from time to time the bed state necessitates early discharge from hospital the mothers and babies come to no harm, but inevitably the domiciliary midwife resents having to visit patients whom she has not delivered. It seems that a prerequisite for routine early discharge from hospital would be unification of the midwives' services, so that patients would not be passed from the care of one organisation to that of another. Such unification is in fact recommended for wider reasons in the report of the Royal College of Obstetricians and Gynæcologists.

The place of the general practitioner in the maternity services was discussed at a conference held last November by the College of General Practitioners,[3] at which arguments were voiced in favour of increasing the maternity beds at the disposal of general practitioners. This is certainly desirable, provided it is recognised that if every practitioner does only his own numerical share of obstetrics he will not have enough continuing experience to remain efficient. (In one large executive-council area more than half the doctors who had expressed their willingness to conduct obstetric cases were found to have dealt with 5 cases or fewer in a year.) Professor **Russell** elaborates this theme and declares that "dabbling in midwifery must be discouraged in much the same way as dabbling in surgery is discouraged. The majority of women will be safely delivered of live infants whatever the standard of work, and the very normality of the reproductive function may blind us to imperfections in care. The practitioner dealing with only a few cases each year may well think that he is rendering an efficient service if only one baby is lost every two years, but this may represent a stillbirth-rate of 5% compared with a possible 1–2%." There are very strong arguments for limiting obstetric practice to a smaller number of general practitioners who have a special interest in the subject and who by training and continued experience can maintain efficiency and merit the name general-practitioner obstetrician.

In replanning the maternity service the importance of the contribution by local-authority clinics should not be overlooked. The staffs of clinics are at present handicapped by lack of direct knowledge of the outcome in cases that come under their care antenatally, and Dr **Sluglett** and Dr **Walker** suggest that these doctors should have the opportunity of attending confinements. There is evidence that in some areas the clinics are being used less than formerly, and where this is so steps should be taken to ensure that the help they offer—notably blood tests, dietary supplements, and education—is not overlooked.

However the service is reorganised, the midwife, the general-practitioner obstetrician, the local authority with all its ancillary services, and the specialist and hospital services will each have a part to play. Once coordination has been improved, there will be room for experiments in the distribution of work between these groups, including experiments with discharge home after different periods.

There can be no doubt that food is far and away the greatest single controllable factor affecting health and disease, but existing knowledge can influence the picture only if effectively applied to the community by means of health education

You point out that research into the origins of degenerative diseases in man is beset with difficulties Not the least of these are encountered in the planning, conduct, and interpretation of controlled human feeding experiments A consequence of this is that even potent nutritional factors affecting human health may continue for a very long time to elude demonstration under conditions which will satisfy the statisticians Moreover, such experiments as have been attempted have often of necessity been carried out under abnormal conditions and for too short a time Results have been inconclusive or even contradictory so that the health educator finds it difficult to be decisive enough to be effective

The most striking improvements in the national health during recent years have been in the younger age groups of the community Whilst in no way minimising the achievements of curative medicine, the fact remains that the children of today are better specimens largely because of the adoption by the community of healthier ways of living encouraged by health education and assisted by improving social conditions

I personally have not the slightest doubt that far and away the biggest factor has been the acceptance by the community of the so called "balanced diet," reinforced by the school meal

Careful inquiry in the home as to what constitutes this "balanced diet" all too often causes me grave concern, but the fact remains that even the orthodox 20th century teachings on fats, carbohydrates, proteins, vitamins, and minerals &c, has achieved a notable improvement on the fodder meted out to the average family fifty, thirty, and even twenty years ago As a direct consequence, and associated with measures to improve the cleanliness of food and milk supplies, we now raise children who mostly survive the perils of infancy, who grow and gain weight at reasonable rates, and who are free from obvious crippling deformities

This is very solid achievement, but a closer look at some of these children will remove any cause for complacency How rare is the bright eyed child, mentally alert, firm of flesh and limb, of good posture, who causes little anxiety to the parents in the matter of general health How very common is the dull and listless child with rotting teeth, deformed dental arches, bulging tonsils, pale and limpid flesh, indifferent posture, constipated, and drifting throughout the winter and most of the summer from episode to episode of sepsis, pyrexia of unknown origin, and general malaise All too often indeed has one encountered this picture even in doctors' families As regards the health of the adult population it may be arguable that that too has shown comparable improvement Nevertheless the appalling volume of digestive, rheumatic, respiratory, circulatory, and mental disorders, reflected in sickness absenteeism, consumption of drugs, and demands on hospital facilities are little short of a national scandal and must surely be a challenge to preventive medicine

Not the least significance of this recent work on the relation of the fats to morbidity is the revelation of further vital substances in common foodstuffs capable of exercising profound physiological influences on the body With scarcely a week passing without that number being added to and the demonstration of deficiency syndromes associated therewith, one cannot but be astounded at the arrogance of those who blandly assure us of the adequacy of denatured diets reinforced piece meal by what they regard as the essential vitamins, &c All the more relevant, therefore, are Sinclair's observations concerning the hazards arising from the national consumption of cereals of low extraction rates and the more timely your own reiterated warning in this respect regarding our daily bread

It seems likely that we shall remain largely at a standstill if we await a strong lead from the laboratory or the field Where can we turn for a clue to the way ahead?

I *contend*, Sir, that we can no longer afford to ignore the fruits of the experience of McCarrison,[1] Picton,[2] Weston Price,[3] Wrench,[4] and many others inspired by them, who have proved for themselves that positive health is attainable by giving due attention to wholeness, freshness, and quality of food, including due regard to the soil in which it is grown

The proof of the pudding is in the eating, and any family who, for instance, will take the trouble to bake their own bread from compost grown, stoneground, wholemeal flour who will eschew, so far as is practicable refined sugars, manufactured sweetmeats, and processed foods and who will include in their dietary significant daily quantities of raw, fresh fruit and vegetables, will reap unmistakable dividends of health even after relatively short periods I single out bread (and would include, of course, other cereal foods, such as cakes and pastries) because I believe in the quantities in which it is normally consumed it is capable of exercising the greatest influence on the family health

The first reaction of the busy housewife may well be to hold up her hands in horror at the thought of the added chore of home breadmaking The ladies assure me, however, that the process can soon be reduced to a fine art Moreover, even the sceptical, having sampled it, seem prepared to make the effort on the commendation of its flavour, texture, and aroma Their testimony to its health giving properties comes later I am informed that at least a hundred housewives in this town alone regularly bake wholemeal bread for the family There is also considerable experience of this sort emerging from residential nurseries and institutions where enlightened dietaries are in force

In view of the urgency of the situation, it would be an encouragement if others with similar family or institutional experiences were to reaffirm them at the present time

Finally, it is to be noted that Dr Sinclair justly *dissociates himself from long-haired naturalism* The fact that, even in his learned treatise, he feels the need to do so suggests to me that as a profession, in consequence perhaps of the extravagent claims and vicious attacks of the naturopaths, we have come to regard the concept of fresh, whole, unadulterated, and naturally grown food as the province of the crank, whereas in truth the only really healthy communities which have ever been demonstrated anywhere in the world were found to be subsisting on just such a diet

RESERPINE IN SEVERE HYPERTENSION

SIR,—Professor Platt and Dr Sears report (April 14) that in three of their female patients lactation developed as a side effect of the administration of reserpine I was much interested in this as my wife has recently observed an apparently adverse effect of reserpine on lactation

A few weeks before term slight hypertension and fluid retention developed 'Serpasil' was prescribed No further rise in blood-pressure occurred, but water retention increased greatly and was only partly controlled by acetazolamide For the first few days after delivery she took no serpasil and diuresis was profuse Lactation started normally and she had a plentiful supply of milk About a week after delivery, serpasil was again prescribed since the blood pressure was still slightly elevated Within a few days, water retention set in and at about the same time the milk began to go back At the end of a week, she had difficulty in satisfying the baby giving him both breasts, whereas formerly she had had more than sufficient milk in one breast She decided to stop taking serpasil Approximately twelve hours later normal diuresis set in again and the breasts became heavily engorged The next day there was again more than sufficient milk and there has been no further trouble

Presumably a good many lactating women have taken reserpine, and it would be interesting to know whether any other similar observations have been made

us week the administration of exogenous hormones in do something to alleviate symptoms in advanced ises He emphasises the need to give hormone herapy in general a more rational basis and he nphasises the difference in response to hormone herapy before and after the menopause Of 17 patients ho responded to androgens 14 had had their first ymptom before the menopause whereas of 14 who nproved with œstrogens, 13 had had their first ymptom after the menopause and there were other ifferences in the behaviour of the two types of cancer **Ellis**[15] and his colleagues also concluded that estrogens were more effective in postmenopausal vomen Foss's view that present techniques are nadequate to detect hormone dependence may be too loomy What is lacking is not the methods but rrangements whereby individual attention can be iven to each patient with breast cancer The recent efinements in the technique of urinary œstrogen etermination, such as those recorded by **Brown**[16] have given these estimations a validity not previously known, and their extended application to problems of this kind, although tedious, is sorely needed

Salute to Adventurers

After the Metropolis Management Act was passed in 1855, forty-seven medical officers of health were appointed to the London districts (they were almost the only ones in the country) and in April, 1856, eight of them met at the house of Dr **Pavy** in Finsbury Square At a further meeting on May 13 the Metropolitan Association of Medical Officers of Health came into being this became the Society of Medical Officers of Health in 1873, and next week it celebrates its centenary

The M O H s of those early days were embarking on a new venture they had scant support from the vestries (who were often openly hostile), they had no textbooks to consult, and they were faced with "those difficulties and perplexities which must inevitably arise from so novel a departure in municipal administration"[17] It was for these reasons, and "to promote efficiency in the discharge of their duties and to aid the progress of sanitary science" that they felt the need for an association Their choice of Sir **John Simon** as the first president must have been automatic After 7 years as the first M O H for the City, he had in 1855 become the first central medical officer of the Board of Health, but the minutes of the association's first meeting show that he was chosen solely for his own qualities "and not in any way because of the office he held under the government" Among his many distinguished successors were Sir **George Buchanan** (1875–77) and Sir **Shirley Murphy** who, as president in the jubilee year (1906), described the society's first fifty years in an address which, with the other contributions to the jubilee number of *Public Health*,[18] gives us a mass of information, not only about its activities but also about the progress of public health in this eventful period Since its jubilee the society's presidents have included Sir **Francis Fremantle**, Sir **William Savage**, Sir **Alexander Macgregor**, Prof R H **Parry** and Sir **Allen Daley** Now in the centenary year this office is fittingly held by Dr **Charles White** who until his retirement a few weeks ago was like the first president M O H for the City of London, but is perhaps even better known both at home and abroad for his previous work in the adjacent post

At first the society concerned itself mainly with sanitary reform and the control of infectious diseases, and it soon began a liaison with Government departments which has steadily improved and which has often influenced legislation An outstanding achievement as long ago as 1877 was the inauguration of a weekly return of infectious diseases among recipients of relief but this was discontinued after a year, despite repeated appeals to the Government, and thirty years were to elapse before the first notification Act was passed in 1889 As time went on more and more attention was paid to personal health and discussions took place on domestic and school hygiene and physical culture, the teaching of hygiene in schools and the control of tuberculosis The early years of this century saw legislation on midwives, maternity and child welfare, school health, and tuberculosis, and after the first world war special groups of the society were formed for the benefit of the assistant medical officers doing this work A fever group was also established a dental officers group came into being, and what is now the Services group, with a membership of 300 past and present officers of the Armed Forces, was started in 1920 Describing, in the centenary number of *Public Health*,[19] the changes that have taken place in the membership and activities of the society, Dr **Stanley Walton** points out that medical officers of health are now in the minority the fellows include university teachers, officers in central government departments, chest physicians, medical journalists, factory doctors, and consultants in infectious disease Partly for this reason many feel that a second change of title would now be appropriate, and it is interesting to see that as long ago as 1905 the alternative name of "United Public Health Society" was suggested—one that would not be out of place today

The society's work was much affected by the National Health Service Act, but its history is full of examples of its ability to adapt itself to such changes It can congratulate itself, among other things, on having continued, after the Act was passed, the activities of its tuberculosis group and on retaining many chest physicians and sanatorium doctors as fellows, for this has done much to counteract the division of responsibility in tuberculosis control which the Act created The fever group has played a similar part But the Act gave the public-health service more than it took away for instance its section 28, dealing with care and aftercare and the prevention of disease, affords (*subject to Ministerial sanction*) almost unlimited scope for excursions into new preventive territory These opportunities have not been overlooked by the society, and its deliberations during the past decade show that attention is now being paid, for example, to mental ill health, the problem family, the care of the elderly, and the expanding work of health visitors, social workers, and

America, have obtained good results by orbital irradiation to a dose of about 900r, this evidently does not work in every case Hermann[2] in Edinburgh has reported 12 cases in which pituitary irradiation brought about most satisfactory results, and in 4 cases improvement was dramatic The dosage she gave varied between 3000r in ten days ,and 5000r over two months Many cases were reviewed four years after treatment, when results remained satisfactory, and there was no mention of any undesirable sequelæ

The value of radiotherapy in this condition should be recognised, and there may be a tendency to exaggerate the dangers of irradiation in the neighbourhood of the pituitary With modern technique, dose calculation is accurate , and, provided excessive dosage is avoided, no ill effects are likely In some cases where pituitary cachexia or interference with hypothalamic structures has followed irradiation of a pituitary tumour, the damage may wrongly have been attributed to the treatment, when actually the tumour was responsible Insertion of radon seeds into the pituitary can cause serious damage, not only to the functional activity of the gland, but to the neighbouring visual tracts , but this should not happen with properly administered external irradiation

D K SAMBROOK

REVISION OF THE CURRICULUM

SIR,—Dr Ellis's plea last week to free the medical curriculum from the restrictions imposed by the G M C recommendations and let it loose for experiment by the various medical schools may be ideal in conception but would, I feel, be chaotic in practice

The result might well be training schemes throughout the country ranging from four to eight years, each reflecting the dominant influence of the particular school or university, and varying in content from my utilitarian ideas to the quite serious suggestion that courses in Latin and Greek should be compulsory for medical students In addition, with the dwindling number of medical students and consequent competition, there would be the temptation to indulge in the " Come to X School " campaigns with attractive slogans such as " Graduate at Y—No Anatomy Required "

I have no doubt that the medical curriculum is, from time to time, considered by the College of General Practitioners, but I have yet to hear of any medical school with G P s on the faculty or committee dealing with medical courses

If the Royal College of Physicians instigated a survey of opinion on the medical curriculum from the medical graduates of this country, I think they might well be surprised at the support for the utilitarian approach

FLUIDS FOR INTRAVENOUS INFUSION

SIR,—Dr Barnard, in his letter of April 28, rightly stresses the need to scrutinise each bottle of infusion fluid when it is opened Pressures above or below atmospheric do not, however, of necessity indicate a fault

Consider, for example, the standard M R C container This holds 540 ml of solution and 70 ml of gas When it is filled and autoclaved the seal being tightly screwed down the gas pressure inside rises and falls to normal again on cooling If the seal is loosely inserted, so that the rubber may move slightly, gas is displaced during heating , but directly the pressure drops, the seal clamps down again In this event there exists a partial vacuum in the bottle, which, tapped smartly with the hand, produces the characteristic rattle known as the ' water hammer " effect

Increased internal pressure may be due to (*a*) slight pressurising of the filling room, to maintain an air flow away from the aseptic area, or (*b*) the difference in temperature during filling and during opening A range of only 10°C, which is moderate, would account for the 10 cm water pressure observed It may happen, too, that at filling the liquid itself is chilled

The fundamental criteria are the sterility and freedom from pyrogens of the solution These are not synonymous, and demand separate tests before the sample is released for use My own handling of several hundreds of thousands of intravenous infusion solutions has convinced me that contamination by micro organisms is exceedingly rare—they are found in one bottle in perhaps fifty thousand Almost invariably the organism is a mould, and it accompanies hair cracks of the base or gross pitting or cracking of the neck of the bottle, presumably as a result of rough handling Bottles which are faulty before sterilising nearly always explode during that process

It is a wise precaution always to scrutinise the sample against a good light, just before administration of the fluid If there is any obvious damage to glass or rubber, or if the solution shows any suspended solid, it should be put aside for further investigation

Southmead Hospital,
Bristol

PETER COOPER

RESERPINE IN ANXIETY STATES

SIR,—Reading the conclusion by Dr Hare and his colleagues (April 28) that there was no general tendency to alleviation of anxiety symptoms in 32 patients who were given reserpine prompts me to comment on the application of the term " tranquilliser " to this drug and cruder preparations from *Rauwolfia serpentina*

The effects of these drugs include depression, usually with extreme agitation and anxiety, insomnia, nightmares, and lethargy—all by now well recognised and frequently reported Now the term " tranquil " usually implies a peaceful, contented state of mind Only " lethargy," the commonest effect (occurring in 16 out of 40 cases of mine), could possibly be mistaken for this but the description given by patients has not led me to believe that such a frame of mind has developed It is described in such words as " I've had all the stuffing knocked out of me," " I've no energy at all," " a nauseating weakness " Tiredness or sleepiness are other terms used To describe such an effect, the word " depressor " would be more accurate , it would also include the quietening effect on noisy psychotics and the mood depressing function which has occurred in varying degree in 14 out of 40 patients

My other objection to ,the term " tranquilliser " is based on the fact that of 12 patients who had obvious mild anxiety symptoms when treatment with reserpine or ' Rauwiloid ' was started, only 2 improved in any degree at all, and 1 of these later developed troublesome dreaming " all night long " 3 became more anxious and agitated and developed marked or severe agitated depression One man who said he was always apprehensive, stated that he was rather more so when on rauwiloid This may not have been due to the drug, but it did not " tranquillise " him This lack of " tranquillising " effect has been remarked on by Joiner and Kauntze[1] among others

The term " depressor " would not of course cover the production of agitation or nightmares and insomnia I would be interested to have a psychiatrist's opinion as to whether the agitation is an effect of the drug or a reaction to depression The insomnia may well be a result of diurnal lethargy and drowsiness, but it is uncertain whether nightmares can be explained in this way

is therefore arisen Those who do ileostomy and excision as a routine admit limited indications for resection and anastomosis (in children, the mentally deranged, and patients with circumscribed involvement of the bowel), but experience has taught them that retention of the rectum, whether anastomosed or isolated, can lead to severe exacerbation of the disease and its remote complications, such as arthritis Indeed perforation and exsanguinating hæmorrhage have been known to arise in the rectum alone The Gordon Hospital group have not, however, experienced any such difficulties, they contend that a low anastomosis with excision of the last inch of colon is the secret of success Time will tell

RECORDS IN GENERAL PRACTICE

THE latest publication[1] in the General Register Office series, Studies on Medical and Population Subjects, carries forward the account of the study[2] of general-practitioner records begun by Dr W P D Logan in April, 1951 Before this date attempts had been made by a few general practitioners to observe and record morbidity in their practices, but this study, in which 8 practices in different parts of the country were covered, represented the first coordinated effort of its kind The inquiry was extended to 2 more general practices, and the latest report includes returns from 13 family doctors, with lists totalling some 37,000, who have recorded each item of service given to their patients

The results are doubly interesting—both as an example of the use of a new research method in a new research field, and for the information gained on the distribution of morbidity in the community The item of service rendered by the practitioner, as reflected in the consultation rate, has been accepted as a valid and useful measure, when considered in relation to the total number of patients at risk While it is easy enough to record that a consultation has taken place, it is less easy to be certain that the cause of the consultation has been correctly assessed From the published tables it is clear that the number of medical certificates of all kinds issued in the practices concerned is high, and it may be inferred that many of the attendances and consultations recorded arose from the administrative need of the patient to obtain a certificate of his disability rather than from the disability itself

The conditions from which the patients were suffering have been classified according to the International Classification, and allowance must be made for the difficulties which were, no doubt, experienced by the Registrar-General's staff in fitting the practitioners' definitions into this pattern Accurate clinical definitions are seldom possible in general practice, and the analysis may be weakened rather than strengthened by attempts at too strict a classification In bronchitis, for example, it is clear that the practitioners who took part had their own ideas about the difference between "acute bronchitis," "chronic bronchitis," and "bronchitis" unqualified It remains to be seen how far agreement can be reached about definitions of disease as first seen in the practitioner's consulting room, and those concerned with statistical evaluation in this research field have to give close attention to this point

The broad morbidity picture recorded in the second and third years of the survey confirms the earlier pattern,[2] and it is now possible to rank the causes of illness and disability in order of frequency of occurrence This study cannot, however, show with accuracy how far the incidence and prevalence of particular conditions are influenced by geographical situation, or, except within broad limits, by type of practice It is to be hoped that the larger investigation which is being conducted by the College of General Practitioners and the General Register Office as a combined operation will provide more precise and useful information Much remains to be learnt about the conduct of morbidity surveys, both large and small, and about specific as well as general aspects of morbidity This work must certainly go on, for an accurate assessment of the community's state of health at any given time can be a valuable starting point not only for further research but for administrative decision and action

B M A AND G M C

THE qualifications and opinions of its direct representatives on the General Medical Council ought to be a matter of some interest to the profession but only by the enterprise of two independent candidates Dr Whiteside and Dr Dillon, was the recent election saved from being a formality Their letter on p 687 will, we hope, lead the British Medical Association to reconsider its procedure over these elections Of course, the association may, as before, see no reason for change it may say, reasonably enough, that like any other medical group it is entitled to propose its own candidates and try to persuade people to vote for them, using its machinery for the purpose But it should understand that this reply will not in fact satisfy those doctors (both outside and inside the association) to whom it has long seemed that election to the General Medical Council takes place by automation from B M A House The fact that the representatives chosen have always given long and useful service to the profession is irrelevant in relation to the real issue—namely, whether damage is being done by depriving a democratic process of its meaning Nobody could expect the B M A to resign its right to nominate candidates, but perhaps thought could be given to some such suggestion as we made six years ago, when we said[1]

> "As things stand, an independent candidate would have to have quite exceptional claims before he could succeed against the B M A 's official nominees, and we suggest that the elections would be given more reality and usefulness if the B M A , *instead of asking voters to keep rigidly to an official list, were to present them with a choice of a dozen or more candidates all of whom would be acceptable to the association If this incidentally improved the chances of an occasional outsider, so much the better* both for the G M C and the B M A , for unreal elections are seldom quite healthy "

A RADIOLOGICAL JUBILEE

ON Jan 6, 1896, the first news reached this country that Professor Rontgen of Würzburg had discovered a remarkable and so far unrecognised form of energy Little more than three months later there appeared the first journal to be devoted entirely to the new science of radiology it was called the *Archives of Clinical Skiagraphy* and it was edited by Sydney Rowland, a young graduate of Downing College, Cambridge From this vigorous ancestor, the *British Journal of Radiology* can claim descent, and this month it celebrates its diamond jubilee In its May issue, senior members of the British Institute of Radiology survey the achievements of these sixty years Prof Gilbert Stead a distinguished teacher of radiological physics, traces the astonishing progress that has brought us face to face with the awesome discoveries of nuclear physics with their enormous potency for good or evil Dr Russell Reynolds, who has studied X rays since Rontgen's day, discusses some of the notable advances in technique which have made diagnostic radiology an increasingly powerful aid to the clinician, and Dr N S Finzi writes, from his long experience, of change and expansion in the methods of radiotherapy Mr Cuthbert Andrews manufactured X-ray tubes for nearly forty years and he has interesting things to say about changing fashions in

FOOTBALLER'S ANKLE

SIR,—We have read with much interest Mr McDougall's article[1] Most osteo articular lesions in athletes give rise to no symptoms, as Mr McDougall points out, but they are clearly demonstrated by radiographic examination, which shows areas of calcification in the articular ligaments or at the insertion of tendons In boxers, for instance, La Cava[2] has found areas of calcification on the dorsal aspect of the hands at the tendinous insertion of the radialis muscle

The lesion of the astragalotibial joint in soccer and rugger players, wrestlers, and skiers has been well known for more than twenty five years[3,4] According to Biolato and Foà,[5] in trained subjects there is notable increase in elasticity of articular ligaments and therefore a wider range of excursion of the joint itself In the ankle joint there is enlargement of the tibiofibular mortise so that the astragalus takes part in dorsal and plantar flexion, abduction, and adduction of the foot This abnormal mobility is the cause, according to Allaria,[6] of the arthrosis of the tibiofibular syndesmosis found in skiers

Such conditions may be due partly to repeated slight trauma to the articular surface[7], but they are largely due to repeated severe stretching of ligaments and tendons This is in agreement with the concept of "chronic entesitis," recently described by La Cava at the Argentine Congress of Sporting Medicine

PARAMETRIOGRAPHY

SIR,—Hysterosalpingography, pelvigraphy, and gynæcography are approved methods for the X-ray examination of the female genital organs Arteriography can give some information about adnexal tumours, but we lack a good objective method for studying the extension of a parametrium tumour or an infiltration of the parametrium Gynæcological palpation gives information on the size of the tumour, but it is often impossible to decide whether the tumour belongs to the parametrium or not In order to overcome these difficulties the following method has been worked out

The patient is placed in the lithotomy position Two long, slightly curved injection needles are inserted 2–3 cm into the tissue about 5 mm lateral to the cervix on each side parallel to the long axis of the uterus The usual intra uterine cannula is inserted into the external os and fixed, and a third needle or thin cannula is introduced into Douglas's pouch The patient is then placed in the supine position on the trochoscope table During fluoroscopy 30 ml of a solution consisting of equal parts of 0 25% lidocaine solution and 35% iodopyracet ('Umbradil') plus 500,000 I U penicillin are injected into each parametrium Then the first postero anterior film is taken After that 10–20 ml of 'Endografin' (Schering) or similar viscous water soluble contrast medium is injected through the uterine cannula during fluoroscopy Films are taken in posterior anterior, lateral, and oblique projections If a tumour found on *gynæcological palpation is not seen* in the parametrium, the patient is placed in the prone position The foot end of the table is elevated about 15° 600–1000 ml of carbon dioxide is instilled into Douglas's pouch during fluoroscopy, and new films are taken

This method has been practised since July, 1955, in patients with acute adnexitis, in order to follow the development of the inflammation, in some cases of sterility and in cases where the findings on gynæcological examination have been inconclusive In all, 40 women, including outpatients, have been examined, and so far no complications have occurred On the contrary, in cases of acute adnexitis injection of penicillin into the parametrium seems to be of value, and is now used in therapy

The results have been very promising In several cases a correct diagnosis of endometriosis was established where "adnexitis" had previously been diagnosed, and in others the presence of extra uterine pregnancy or ovarian tumour, diagnosed by this method, was invariably confirmed at subsequent laparotomy

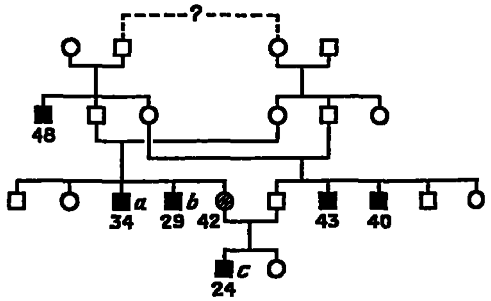
PEPTIC ULCERATION IN A FAMILY

SIR,—The accompanying figure, showing the pedigree of an intermarrying Tripolitanian Jewish family, may be of interest in view of the stress now laid on the psycho somatic ætiology of duodenal ulcer 7 members of the family had peptic ulcer, of these I know personally (*a*), (*b*), and (*c*), and in the remainder the diagnosis was confirmed radiographically Wright et al[1] recently described a family in which 9 out of 13 living siblings, have duodenal ulcers



Family with 7 cases of peptic ulcer (black = duodenal ulcer, hatched = gastric ulcer) Figures indicate age at onset

KETONURIA—A FALLACY IN ROTHERA'S TEST

SIR,—The standard textbooks on sideroom work and urine-testing state that there are no fallacies in Rothera's test for ketones There would appear to be one fallacy which may occasionally cause confusion

A male diabetic, aged 56, was admitted to hospital for review and stabilisation Mild ketosis and glycosuria were present on admission The glycosuria rapidly disappeared on adjusting the insulin dosage, but, despite the absence of other clinical or biochemical evidence of ketosis, routine urine tests by the nursing staff repeatedly showed "acetone present" The ferric chloride test was negative, and on checking the nitroprusside test the addition of ammonium hydroxide led to an immediate colour reaction, but the colour was not the typical purple normally seen in ketonuria Investigation revealed that the patient was receiving an aperient containing a small amount of phenolphthalein, and this drug, excreted in the urine, was producing the colour change in the presence of free alkali

This fallacy in Rothera's test is not generally recognised and might, if overlooked, lead to insulin overdosage It was found that urine containing phenolphthalein did not produce a colour change on 'Acetest' tablets, and the Ames Company Ltd, which manufactures these tablets, has kindly confirmed this by more accurate investigations The use of the tablet method of testing for ketones will, therefore, avoid this fallacy, which should perhaps be recognised in the teaching of medical and nursing students

I am indebted to Dr J A W McCluskie for permission to publish this case

HOME CONFINEMENT *

C S RUSSELL

MA Oxfd, MD Edin, FRCSE, FRCOG

PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY IN THE UNIVERSITY OF SHEFFIELD

Professor Claye, of Leeds, has recently said that domiciliary delivery deserves to be as dead as the odo and already it is in that desirable condition two of the more civilised countries in the world "[1] e was speaking of Australia and New Zealand He went n to say that "alone among the more populous countries the English speaking group Great Britain remains ld fashioned" Against this opinion may be set the ct that in Holland an efficient home service has been ported by Professor ten Berge[2], and Dr L Roberts, ur medical officer of health in Sheffield, has expressed he opinion that the home should be the best place for woman to have her baby[3]

The General Practice Review Committee of the ritish Medical Association were firmly of the opinion hat midwifery, and not only home confinement, is an ntegral part of general practice, and that every possible ncouragement should be given to general practitioners to ndertake it About half the practitioners answering questionary said that they liked midwifery, and ished to increase their experience, a third undertook ases only when specially asked to do so, and the emainder wished to discontinue it[4]

Maternity Medical Services in the Home

he General Practitioner

Under the present arrangements an expectant mother nay, if she wishes, make arrangements for a doctor to rovide her with maternity medical services These ervices include

(*a*) Antenatal care throughout pregnancy (including an nitial antenatal examination and one at the thirty sixth veek of pregnancy)

(*b*) Attendance at any emergency in connection with the regnancy if the doctor is summoned on the patient's behalf

(*c*) Attendance at the confinement if the doctor thinks it necessary or is called in by the midwife

(*d*) Medical supervision of the mother and child during he puerperium

(*e*) Postnatal care of the mother, including a pelvic xamination at or about the sixth week after confinement Why the postnatal pelvic examination is named, rather than an antenatal pelvic examination, is not clear to me I should have thought the latter was much more important]

The family doctor may provide maternity medical ervices for a patient who is on his medical list, and he is paid a special fee for these services There are, however, certain doctors whose obstetric experience has been approved by the local professional committee The names of these doctors are shown separately or are specially mentioned in the executive council's list They are entitled to a higher fee, if in an emergency they are called in by midwives to patients for whom they have not previously arranged to provide maternity medical services, they are entitled to a fee from the local health authority If the family doctor does not wish to undertake the maternity care of one of his ordinary patients, he will advise her to consult one of his colleagues on the obstetric list

The mother receives the services free of charge, and the doctor is paid a comprehensive fee by the executive council

The Local Health Authorities

Besides the services given by general practitioners, the local health authorities have a duty to provide ante natal and postnatal clinics for the regular supervision and care of expectant and nursing mothers Routine medical examinations and special investigations are undertaken by these clinics, welfare foods and simple medicaments are supplied, detailed advice on mothercraft is given, and where practicable, priority dental care is provided The clinics are in fact centres for all the educational and social work that is so desirable for pregnant and nursing women They are held at the maternity and child-welfare centres, where the authority's midwives and health visitors normally work

Under the 1936 Midwives Act the authorities also have to secure that there are enough midwives in their area If the mother chooses to have a midwife rather than a doctor, to attend her, the midwife will call in medical aid only if this is required The cost of this is met by the local health authority The authorities also have the power, though not the duty, to provide domestic help in households where this is needed

The Midwife

A word must be said at this stage about the midwife In the past she was often decried, sometimes with much justification, and even today some people think of her as a modern Sarah Gamp The Working Party on Midwives remarked that "with past intolerance equally distributed (between doctors and midwives) the way should be smoother today for that integration of midwifery and medicine which we regard as essential to the most profitable employment of both" But encroachment of the doctors they said, is not in itself sufficient to account for the failure of midwifery as a profession for women Another reason is that, while the public has gradually become nurse-conscious, it has not, at the same time, become midwife conscious Victorian prudery which shrouded everything connected with childbirth in an almost impenetrable mist, is not yet dead

In 1948 a municipal midwife, because of shortage of accommodation, was quartered in a small private hotel She was requested not to use the general lounge because her presence might embarrass the other guests

My view is that the woman who is in attendance at labour must be someone of education, who is properly trained, and who has a pride in her work But how can she have the sense of a job well done unless she is encouraged to take responsibility both during labour and in the antenatal and postpartum period? This encouragement must come from medical men and women, for nobody else is likely to give it to her I am sure that unless we adopt a proper attitude to the best of our midwives, we shall be laying up for ourselves and for our children a store of trouble Midwifery recruitment will fall, and a profession which is not yet all that respectable will fall on evil days

It is quite clear to me that neither the doctor nor the midwife must monopolise the patient but that they must work together as a team, and I accept the Royal College of Midwives' view that "the function of the midwife should be substantially the same whether she is engaged in institutional or domiciliary practice"

The Divided Responsibility

The responsibility for maternity care is divided between those employed by executive councils, local authorities, boards of governors, and regional hospital boards, so we cannot easily agree as to what are the best arrangements for each patient This need not surprise us for reason to be proud of estimates for the present financial year True, another £12 million was provided for hospital boards, an increase of about 4%, but a little over £7 million of that would go to meet wage-claims and rising food costs Precious little improvement of the service would be available out of the extra money

Training of Mental-health Workers

Raising this subject in the House of Commons on April 30, Mr KENNETH ROBINSON said that ideally the future of the mental-health services lay not so much in having more and more beds as in emptying the mental hospitals and in preventing people from having to be admitted to them This could only be achieved by extending and improving outpatient facilities and community and domiciliary services The local health authorities were responsible for these latter services, and their instruments in carrying out these duties were the mental-welfare officers and the psychiatric social workers He thought it odd that though both carried out highly responsible duties the P S W s were highly trained and the officers not trained at all

In 1951 the Mackintosh Committee recommended that there should be a substantial increase in the number of P S W s and pointed out that the mental-health service demanded a large number of trained mental-welfare officers These officers were responsible for prevention and aftercare among mental patients and perhaps their most important work was done in their capacity as duly authorised officers The duly authorised officer often initiated the whole procedure of certification, and he might indeed be the first contact between the members of the public and the mental-health service He could, and often did, override the opinions of general practitioners on patients suffering from mental disorder One would imagine that these officers would undergo a rigorous and extensive course of training and obtain some kind of national qualification, but nothing of the kind happened The Minister of Health in reply to a question had admitted that there was no national scheme of training, though some local authorities arranged courses The Minister had added that the position was being studied by a working party But immediately after the issue of the Mackintosh report, Mr Robinson recalled, an ad-hoc committee was formed, with representatives from the universities, the Royal Medico-Psychological Association, the National Association for Mental Health, and the Society of Mental Welfare Officers They had submitted proposals about training to the Minister in 1952 After 18 months the Minister wrote saying that the question could not be considered until the Working Party on Health Visitors, under Sir Wilson Jameson, had reported The mental officers themselves appreciated that their increasing responsibility demanded a high standard of competence, national training, and qualification, especially for new entrants into the service

Some months after the receipt of the Minister's letter the various bodies worked out an actual syllabus for a year's course The National Association for Mental Health agreed to organise a scheme and a further approach was made to the Minister with the same negative result Now, when the Jameson Working Party was almost ready to report, the bodies concerned were asked to await the findings of yet another committee, the Younghusband Committee on social workers, which meant a further delay of anything up to two years

Turning to the psychiatric social workers, Mr Robinson said that for them there was an established training of a high quality, but there were not enough training facilities and not nearly a large enough output In its recent report the Committee on Maladjusted Children estimated that for a satisfactory child-guidance service alone four times as many P S W s were needed—420 instead of the present 109 , hospital authorities also needed more, for vacancies existed in every mental hospital There was thus an acute shortage of these workers and the training was stiff In his view the salary range of £495–750 p a was not sufficient incentive for the right kind of people

Miss PATRICIA HORNSBY-SMITH, parliamentary secretary to the Ministry of Health, said there were 1100 mental-welfare officers in the local health authority services Many had considerable experience from the days when the local authorities ran their own mental hospitals, and it should not be suggested that they were not doing their job satisfactorily The advice of those who had had long experience was available to new comers Many local authorities were providing training courses, some at universities and some within their own organisation, including secondment to a mental hospital She realised, however, that more courses were needed and she appreciated that the professional associations representing welfare officers felt strongly that there should be a properly recognised training

The Mackintosh Committee were set up before the new pattern in the mental health service evolved By their terms of reference they necessarily considered mental health workers in isolation But barriers between the mental and the physical health services were breaking down and we no longer regarded mental-health work in a vacuum It might well be that from the reviews of the Working Parties on Health Visitors and Social Workers there would emerge a new concept of social welfare workers and the kind of training suitable for them

Another report which the Government could not ignore in plans for mental-health work was that of the Royal Commission on the Law Relating to Mental Illness and Mental Deficiency (now sitting)

She sympathised with welfare officers who had waited so long and patiently, but while it was essential that they should be properly fitted to discharge their functions she did not agree that social work for the mentally ill could never be combined with work for those who were in difficulties in other ways Sometimes it might be an advantage in obtaining the cooperation of a family if the trained worker came to them as a welfare visitor and not exclusively as a mental-welfare worker There was also an advantage in the hospital P S W having a wider sphere of activity, since he was the link between the patient and his home and friends and the medical and nursing staff of the hospital or clinic These workers took a two-year social science course at a university, followed by a year's practical experience, and then a university mental-health course The Minister assisted with grants for the university mental-health course Since 1949–50 the grant had been £8000 and the average yearly intake of students for these courses was about 50 She did not deny that there was a shortage of these workers, but estimates of the number needed varied from 870 to 1500 According to the Association of Psychiatric Social Workers the number of qualified workers was 447, but that did not include many local-authority workers who, though they had not taken the recent specialised training, were qualified by long experience Similarly hospital returns showed that they had 311 whole-time workers of whom only 182 were included in the association's estimate The Government did not believe that greater numbers of students would automatically be forthcoming if more courses were provided or if the scale of the Government contribution were increased

QUESTION TIME

Smoking and Lung Cancer

Mr J K VAUGHAN MORGAN asked the Minister of Health whether he was now in a position to make a public statement as to the effect of smoking in producing carcinoma of the lung —Mr R H TURTON replied Since my predecessor made a statement in February, 1954, investigations into the possible connection of smoking and cancer of the lung have been proceeding in this and other countries Two known cancer producing agents have been identified in tobacco smoke, but whether they have a direct rôle in producing lung cancer, and if so what, has not been proved The extent of the problem should be neither minimised nor exaggerated The number of deaths from cancer of the lung has risen from 2286 in 1931 to 17,271 last year To place the figures in perspective—in 1954, out of every 1000 deaths of men aged between 45 and 74, 77 were from bronchitis, 112 were from strokes and apoplexies, and 234 were from cancer, of which 85 were cancer of the lung Deaths of women from cancer of the lung are still not very significant and represent a small fraction of the total

The chairman of a committee of the Medical Research Council which has been investigating the subject considers that the fact that a causal agent has not yet been recognised should not be allowed to obscure the fact that there is, statistically, an incontrovertible association between cigarette smoking and the incidence of lung cancer The statistical

TABLE II—AGE DISTRIBUTION OF 160 WELFARE CASES AND 103 DOCTORS' CASES IN THE 1953 SHEFFIELD SAMPLE

	Age groups	
	Under 20	Over 20
No of welfare cases	8	152
No of doctors cases	1	102

pressure to get a hospital bed. We who have the responsibility for deciding who should occupy the beds under our care may find ourselves in an uncomfortable situation. On the one hand, we have those who are trying to get another case into hospital, and, on the other, those in hospital management and nursing who have to provide all the non-medical services, and who often want to keep the case out.

Doctors' Cases

The age and parity distribution of those booking family doctor first, but who do not normally have antenatal care at the welfare clinics, is not remarkable, except when their ages are compared with those attending the welfare clinic first (table II). Those under 20 years of age usually went to the clinic first.

Whereas before 1948 comparatively few women booked doctors as well as midwives, under the National Health Service the services of both are available without charge, and over half the women now confined at home book a doctor. He accepts responsibility for the case and may, at his discretion, attend the confinement or leave it to the midwife.

More and more general practitioners are also providing antenatal care for their booked patients, and local health authorities are encouraging midwives to work in association with the doctors. "There is thus at present a transitional stage in which medical antenatal care for domiciliary cases is changing hands"[7]—and, if general practitioners and midwives give a better service under the new conditions, this change is all for the good.

Personal preferences of the patients also play a part. As the wife of a traffic manager said, "Everybody doesn't like to meet what you have to meet at antenatal clinics"—though it is only fair to add that she was equally critical of her own doctor's supervision.

A history of previous abortion, difficulty with pregnancy or labour, or stillbirth or neonatal death, is less frequently encountered in the group booking the family doctors than that which attends the maternity service of the local health authority. Social class probably still largely determines whether the patient goes first to a family doctor or to a welfare clinic, and as social class and reproductive performance are closely linked, there is nothing surprising about this difference. There is, however, one other conclusion that can be drawn from this comparison. The domiciliary midwives in Sheffield, working on their own, have a more difficult type of case to look after than those who only assist the family doctors. Whether we should praise them for their enthusiasm or criticise the arrangement is debatable.

Are More Hospital Beds Required?

The Ministry of Health advises that "unquestionably most multiparæ who have had four or more children would be within the group having medical reasons for admission"[8]. If we accept this view, and if we add all patients over the age of forty, all who have had a previous abortion, previous pregnancy or labour difficulty, stillbirth, or neonatal death, we find that 41 of our 161 welfare patients (and 17 patients booked with general practitioners) should not have been booked for home confinement. To these we may add 26 primigravidæ and 32 parous women, who wanted a hospital bed, then we may deduct those whose booking arrangements were subsequently changed, and reach the grand total of 95 cases, the equivalent of just over 1100 cases a year.

This figure does not take into account primigravidæ who have booked a doctor but would have preferred a hospital bed if it had been available, or parous women who have given up trying to get a bed, nor does it take into account the relatively short stay in hospital (not more than ten days) that is all that can be offered to patients who are taken in. This last point is a matter about which some senior hospital midwives hold strong views, maintaining that if only we kept our patients for the full fourteen days, very much would be gained, especially in respect of breast-feeding. For myself, I am not convinced that an extra few days in hospital would make so much difference. What concerns me more is that the rapid turnover in institutions makes it very difficult to keep the risk of cross infection negligible.

In round figures it may be said that at least 1000 extra deliveries might well take place in institutions, which—surprisingly enough—would bring the proportion of institutional deliveries for Sheffield up to only 70%.

Selection of Cases by the Hospitals

Could the hospitals improve their ways of selecting cases, and could they find beds for these hundreds of women who perhaps ought to come in? No doubt some better selection is possible, but it is extremely unlikely that any substantial adjustments can be made.

I do not altogether hold with the policy of first come, first served, but there is much to be said in its favour. At least it encourages early antenatal care, which allows us to examine patients when their natural state of health is not materially altered by the pregnancy, and to deal with any gross abnormality, such as an ovarian tumour, expeditiously and with the least risk.

My figures show that in the teaching hospitals patients attend early—a practice which must, by modern standards, be encouraged. In the non teaching hospitals a substantial proportion of cases are booked because of adverse home conditions. If they keep out patients who should come in for more obstetrical reasons, it is just one of the deficiencies of the service. Examining such data as I have, I cannot see how beds can be found for any but a handful of the many hundred cases who really should come in.

Possible Improvements

In my view, all is not well with our maternity services, but to find ways to improve matters is not so easy.

More Maternity Beds

Taking the long view, we should, I believe, press for extra maternity beds, but who is to provide them, and who is to look after them when they are provided?

Taking the first point first, I like the idea of the local authority and regional hospital board providing them as a joint centre for domiciliary midwives and for selected general practitioners. The local authority must be included, for they have many responsibilities for the care of the pregnant woman over and above what the general practitioners have time for. The day to day running of such a home could very well be in charge of the local authority midwives who are already doing this in the patient's home, and general practitioners could be appointed to do the day-to-day minor obstetrical procedures. I feel very strongly that some supervision, maybe even control, should be in the hands of the consultants, or at least doctors who have the necessary experience to advise on obstetrical matters.

Aristocracy of General Practitioners

Though we should have extra maternity beds, I do not think that we want more hospital maternity beds—with the full complement of consultants, registrars, and house-surgeons—for an increase in the number of hospital beds would still further dilute the material available to the general practitioners. The arrangement I have suggested would have the support of the Central pulled down and 75,000 people were rehoused This year he hoped that these figures would be substantially higher, and he was confident that before long we should reach the target—namely, to rehouse every year at least 200,000 people from the slums

London's Drainage

The London County Council is to consider next week the proposals of the rivers and drainage committee for a major programme of improvements estimated to cost about £9³/₄ million at the council's southern outfall main-drainage works The scheme involves large civil, mechanical, and electrical engineering works and buildings, and will, together with the equally large improvements already well advanced at the northern outfall works, considerably improve the condition of the Thames

Infant Mortality in Scotland

In Scotland the infant-mortality rate in 1955 was 30 per 1000 live births [1] This rate is the lowest recorded in Scotland, being 1 below that for 1954 and 5 below the five years' average

Notes and News

THE TEACHING HOSPITAL AND THE UNIVERSITY

AT the annual meeting of the United Sheffield Hospitals on April 26, SIR FRANCIS FRASER considered what a teaching hospital should aim to provide for its university, in the light of Wilfrid Trotter's assertion that clinical medicine is compounded of practical art, applied science, and experimental science

" Science, or rather the scientific method," said Sir Francis, " requires that a conclusion in any situation be reached only when the evidence is complete and that until then judgment must be left in suspense In the practice of medicine it is clearly unjustifiable to suspend judgment and its consequent actions in this way, and so the clinician brings to his aid a practical art For this he requires experience of similar situations, a cultivated intelligence, and knowledge of and sympathy with human beings of all types " It is in the teaching hospitals that the future practitioner forms his habits and his attitude to sick persons " Is there perhaps a tendency in teaching hospitals, occupied as they must be in providing for the more material requirements of diagnosis and treatment of serious disease, to let this aspect of the care of patients look after itself and to take it for granted ? Each of you must have received on frequent occasions the story of the patient anxious and fearful of the unknown being kept waiting in unattractive surroundings for hours perhaps before an overworked member of the staff is able to give him or her a few minutes' attention, only to refer him to another department where the same thing happens What the patient wants above all is to pour out a story to a sympathetic and understanding physician and to receive comfort and encouragement That is the essence of the art of medicine Are the practitioners of the future who are being trained as much, or perhaps even more, by example as by precept receiving the influence which it is our duty to provide ? "

Turning to clinical medicine as an applied science, Sir Francis remarked that clinical trials, based on observations in animals, can be adequately provided for only in teaching hospitals, where clinicians can cooperate with the staffs of the university's basic science departments " Every teaching hospital should be sufficiently elastic in accommodation and staff to be able to contribute to investigations of this type, and teaching hospitals have the responsibility to encourage them " The development of medicine as an experimental science—now usually known as clinical science—has led to the appointment of whole time heads of departments of clinical medicine and clinical surgery, with whole time staffs to assist them and with laboratories close to the wards A few pædiatric departments are similarly staffed and equipped, and before long workers in other specialties will need similar opportunities " I have visited many teaching hospitals in this and other countries, and no matter how recently they have been planned and built there is always the same experience—that the laboratory accommodation for the clinical departments is much too small I would suggest that laboratory accommodation adjacent to wards is likely to be wanted in the near future on a scale that may well seem fantastic at present "

In conclusion Sir Francis urged that the main teaching hospital of a university should contain at least small departments and a few beds devoted to each of the specialties " Only in this way can each specialty be inspired by the advances taking place in the others and enabled to share in the new knowledge and methods For the care of the patients of the community, by means of the applied science and the art of medicine, these special departments may well have larger units in other hospitals in the area, but they should all share in the invigorating intellectual environment of the university clinical centre "

THE NATURE OF GENIUS

THE centenary of the birth of Sigmund Freud was commemorated at a meeting held in London last Sunday by the International Psycho Analytical Association, when Dr HEINZ HARTMANN, the president, took the chair, and Dr ERNEST JONES gave the Freud memorial lecture

The question whether there really is such a thing as genius—that is to say, any attribute that differs in its very nature from those present in all human beings—Dr Jones answered with a decided No the differences between individuals, and between races, are quantitative rather than qualitative ith the district midwife at one of the local-authority linics In Bristol general practitioners can already ndertake the antenatal care of their own patients, hether booked for hospital or home confinement, in ocal-authority clinics The scheme is closely linked ith the consultant service, obstetricians from the main ospital centres holding regular sessions at each clinic, o which patients can be referred by the general practitioners The local authority's medical officer covers the antenatal supervision of mothers whose own doctors do not practise midwifery The district midwives share with he doctors the antenatal care of mothers booked for domiciliary confinement The expectant mother is thus able to attend at one centre near her home, where all members of the obstetric team are available (Redman and Walker 1954)

General Outline

The scheme we have in mind would require a block of labour wards attached to a maternity hospital Each would consist of a suitably heated room with simple equipment such as would be found in a good household which has been prepared for a confinement—i e , bed, cot, wash-hand basin, and so forth Except for preparing and cleaning the room, no extra staff would be needed When the woman went into labour she would inform the district midwife who would arrange for her admission to this labour-ward and accompany her there If the midwife undertook pupil-training, a pupil would also attend The patient would not be left by herself at any time during her labour Her own doctor would be informed at once and, with the midwife, would be responsible for the conduct of the case When the mother had been safely delivered and had recovered from the effects of her labour, she would be taken home by ambulance with her baby, accompanied by the midwife Nursing would then be continued as for a home confinement This scheme would have the following advantages

1 The delivery would be conducted under ideal conditions If any complications should develop, all the resources of the maternity hospital would be easily available

2 The mother would have a sense of reassurance knowing the resources of the hospital were there if wanted

3 She would be attended at her delivery by her own doctor and midwife Continuity of care and personal relationship is extremely important As one mother said "I should feel more confident if I knew I was being looked after by people who not only knew my case but knew me."

4 A relative or friend would be allowed to accompany the mother, if desired

5 The risk of exposure of mother and baby to hospital cross-infection would be greatly reduced

6 Most mothers in hospital begin to fret after the first few days and we feel sure they would be glad to go home so soon

7 There would be considerable saving of public money

Discussion

With the excellent transport now available, there is no clinical reason why most mothers who have had a normal confinement should not go home soon after delivery Owing to shortage of beds this sometimes happens now, and no harm follows We see little difference between transporting the patient by trolley from a labour-ward to an ordinary ward and transporting her from the labour-ward to an ambulance, under cover and so to her own home In fact, we believe that a return home so soon after delivery is preferable to discharge from hospital on the 4th or 5th day If the patient goes home at once, arrangements will certainly be made for domestic help, but if she goes home later she may well have to start household duties long before she is fit

The time for sending the mother and baby home will, of course, vary and must be left to the judgment of the team It would normally be about the time when a midwife would leave a case after completing a home delivery The midwife would have to give extra time here to see the mother and baby safely home and comfortably settled A similar procedure of immediate return home has been reported in a fairly large series of hernia repair operations with excellent results (Farquharson 1955)

The incidence of hospital cross-infection, especially with resistant strains of staphylococci, is a matter of concern and maternity hospitals and their attendant nurseries are not immune In the labour-units we have described, neither mother nor baby would normally come into contact with hospital personnel or other patients

There would have to be more strategic planning of the actual confinement, and detailed arrangements for the reception and care of mother and baby on their return home would need to be made well in advance The scheme would need more domiciliary midwives and a larger and more flexible home help service but it would still cost far less than a greatly enlarged maternity unit or a new maternity hospital Midwives in maternity and general practitioner hospitals could be released to work on the district

In our opinion these cases must be regarded as home confinements and qualify for the full maternity grant After all, the grant is intended to cover not the actual delivery but the puerperal period when home help is most needed We also think that consideration should be given at a national level to reducing the charges made for the home help service in maternity cases The differential grant of £4 does not cover the cost of a home-help for the lying-in period except for a few cases who qualify for a reduced charge under existing assessment schemes We think it unfair that the mother delivered and nursed in hospital should have this economic advantage over her sister who is nursed in her own home

If the majority of mothers came to be delivered in these G P labour-wards, arrangements for training medical students and pupil midwives would need modification We see no reason why training should not be carried out under the ægis of this general-practitioner/midwife team We do not think it unkind to say that many of us are not happy about the way some medical students have floundered through the district-midwifery part of their training In the scheme we propose the young student or pupil midwife would be closely supervised at each delivery until he or she were confident enough to be in charge of a case

The scheme would be best suited to large towns, but there is no reason why it should not apply to the less-scattered rural communities The labour-wards would have to be opened where accommodation at a maternity hospital could be found and according to population requirements Where there is already a maternity hospital we suggest that one of the wards could be divided into rooms All dressings, instruments, and the like would be provided by the hospital. Put in homely language we should be simply renting a room for a short time The conduct of the case would be in the hands of the G P -obstetrician/midwife team with or without a pupil, and be completely outside the jurisdiction of the medical or nursing staff of the hospital The scheme would deal only with "normal" confinements Abnormal cases booked for hospital and emergencies would pass out of the care of the general practitioner or the local authority on admission to hospital Some "social cases," where home conditions were unsatisfactory, would need to be retained in hospital for the lying-in period and would therefore come under the supervision of the hospital staff

The original intention of the "obstetric list" was that midwifery should be practised by a limited number

University of Cambridge

On April 28 the following degrees were conferred

M Chir—C Q Henriques *
M B, B Ch—A B L Peake *
M B—Rachel D Hudson Frank Summers

BIRTHS

BAKER—On May 2 to Dr Hazel Baker (née Hill) wife of J A C Baker M A of Wednesbury, Staffs a fourth son—Edward James

JACKSON—On May 1 to Eileen (née Greenwood) M B and John W Jackson M CH F R C S—a daughter, Jennifer Mary

She was 74 She had severe claudication When she as admitted to hospital there had been small areas gangrene on one foot, but these had now separated ad she was up and "pottering" Soon she was to be ischarged and sent home

Let me see Mrs ——, you live by yourself don't you ?

No doctor, with my sister

How old is your sister ?

She s 80

Then I suppose she is in no state to look after you

Oh, yes, she is doctor, but I have to look after her because he goes out to work.

Goodness gracious, at 80 What does she work at ?

She works on a capstan

Part-time ?

No, whole time We get up at half past five in the morning to get her off and she gets back to her supper at even

Well, could you get a home help to come in each day ?

But who s going to pay for it, doctor ? I've only my pension

What about your sister ? She earns big money

So she may, doctor, but she saves for her old age

First Child ($5^{1}/_{2}$) has just been to his first film My husband selected *The Wizard of Oz* as suitable, enjoyable, and not terrifying I was assured there were no witches and it was all lovely colours and mild as milk. So I got a school-teacher friend to come too, with her carefully brought-up little girl ($4^{1}/_{2}$) We arrived just after the beginning, which was monochrome and about a farm in Kansas The children didn't seem to mind, though we wondered if it was the right performance · After what seemed a long time to us and $^{1}/_{4}$ lb mixed sweets to them glorious colour sequences ran riot over the screen, and the magic word "Oz" was mentioned, so we knew we hadn't made a mistake (or had we ?) From then on there was hardly a witchless moment, not to mention clouds of sulphurous smoke, bangs, orange flashes, and scarlet-mouthed hydrocephalic familiars First Child crouched very close to me, completely absorbed, refusing stoutly to come out, though frankly admitting terror $4^{1}/_{2}$ was made of sterner stuff and bounded up and down, inexorably questioning her mother The songs bored both of them, and finished the sweets I kept assuring my son that all would be well, as it always was in films, but he reminded me vividly of a rabbit too near a stoat The whole party was relieved when the worst witch was melted, and $4^{1}/_{2}$ was hurried off to seek a different kind of relief To the strains of *Home Sweet Home*, with the heroine mysteriously restored to her Kansas farm, we left in good order to catch our long-past-bedtime bus $5^{1}/_{2}$ said it was a smashing film, and of course he was frightened, but he wouldn't have missed it for anything $4^{1}/_{2}$ said were there any more liquorice allsorts My friend said she didn't *think* it would do any lasting harm I said I'd have a word or two with my husband on the subject of nightmarish films for impressionable children

Guess who had the nightmare ? $5^{1}/_{2}$ and $4^{1}/_{2}$ slept peacefully till morning "I wish you'd stop kicking and screaming about witches," my husband said irritably "Heaven knows what you'd be like after an A film !"

Not every diabetic's mind
Is mathematically inclined,
(Nor, parenthetically, is mine)
And so we seek a standard sign
No wonder, then our reason teeters
Between ccs and millilitres
Between the barrel and the label
There mounts a metric tower of Babel ,
Yet since it gets beneath our skin
We must inject our insulin
So Makers, though our ampoule smiles
Approve your standard colour phials,
However lunatic our fringe
We must employ a marked syringe—
So make your vitreous incisions
Not, please, in units, but divisions

Letters to the Editor

G M C ELECTION

SIR,—We were the two younger and unsponsored candidates at the General Medical Council election Each of us stood because he wished to represent the active practitioners of the National Health Service, who are at present inadequately represented on the General Medical Council We had lunch together and then attended the count at Hallam Street, being the first candidates to do so in living memory We should like to take this opportunity to thank Mr W K Pyke-Lees, the registrar, and Mr C O Weston who showed us the electoral machine in action This was of exceptional efficiency, and we were both much impressed by it

Our abiding memory, however, will be of the way in which the whole might of the British Medical Association was thrown into the fight to keep us off the council There were two paragraphs in separate issues of the *British Medical Journal* extolling B M.A candidates, and about 45,000 members of the profession in England received two well-timed circulars We estimate that the cost of this was some £2000 of Association money Neither of us was in a financial position to act likewise, nor do we agree with the principle of canvassing by pressure groups

We still hold that the direct representation on the General Medical Council should be representative of the profession at large, not excluding the younger groups We therefore believe that reform of the electoral procedure is necessary We hope that our candidature will have pioneered the way towards this Finally, we should like to thank the doctors who voted for us with 16,000 votes Perhaps we shall have better luck and a fairer chance next time

Rugeley Staffs — STANLEY DILLON

FATS AND DISEASE

SIR,—Like many of your readers, I am sure, I wonder whether this work on E F A[1-3] may be a major breakthrough into the explanation of coronary heart disease I have been mulling over the data on fat consumption and "atherosclerosis" for years, but have always come away with the feeling that, though there *must* be something in it, the story as usually told—whether in terms of total fat in the diet the proportion of calories derived from fat, or animal *v* vegetable fat—just would not stand up It may well be, as is now suggested, that what we were getting was a blurred version of a more complicated story that includes the ratio of E.F A to other fatty acids

Permit me, therefore, to make two observations that may help to clarify future discussion, now that an additional factor has been introduced First, there is the common idea that the prevalence of coronary heart-disease in different countries is in step with what is known of their fat consumption Second is a question about possible misconceptions in current research

The facts about prevalence are mainly of two kinds mortality-rates produced in the various national offices of vital statistics , and the results of ad-hoc clinical surveys As regards the former, the frequent statement that total fat in the diet is closely correlated with mortality from ischæmic heart-disease is incorrect, at any rate for comparable Western peoples There is wide variation in the certified mortality from coronary heart-disease among countries with very high fat diets Thus

---

difficult to identify in its earliest stage Such terms as "invasiveness" and "invasion of the stroma" are thus difficult to define To take one example the histological characteristics of lymphosarcoma in its earliest stages are not at all sharply defined—hence the occasional use of the term "diffuse lymphocytoma" to describe the pattern of the lymph-node which has lost most of its normal architecture but whose constituent cells are not yet frankly malignant—but one of the criteria frequently accepted as indicative of malignant behaviour is "invasion (or transgression) of the capsule" In the advanced case transgression of the capsule is likely to be obvious, but if one looks for this in all surgically removed lymph-nodes one will see it remarkably often This fact illustrates the circular argument into which we are so apt to fall when trying to lay down diagnostic criteria The argument is that, since lymphosarcoma always shows capsular transgression, capsular transgression always indicates lymphosarcoma, whereas, in fact, it does not There are also sites such as the thyroid and prostate where "invasion of the stroma" is commonly diagnosed, although in fact this diagnosis is rarely justifiable on the microscopic appearances alone Indeed, if the epithelial elements still remain within the anatomical capsule of the thyroid or the prostate it is doubtful if the microscopist can rightly recognise invasion of the stroma at all

We thus seek a finer criterion of invasion Can it lie in "*rupture of the basement membrane*"? Nearly all epithelium has a basement membrane, and rupture of this membrane should, one would think, provide a fairly reliable criterion of malignant growth Again, however, the histopathologist is disappointed The exact nature of a basement membrane is still not known for certain, nor are the factors which may lead to its disappearance It may certainly disappear, or at least become undemonstrable by ordinary staining techniques, in areas where there is chronic inflammation, as in chronic cervicitis or peptic ulceration—an unfortunate fact from the diagnostic point of view since it is so often the small, ulcerating lesion that causes diagnostic difficulty In my own view, the integrity or otherwise of the basement membrane is of little or no value as a criterion of malignancy

A final criterion is the presence of *neoplastic tissue within blood or lymph vessels* Provided that both the vessel and the neoplastic tissue can be indubitably recognised, this criterion may certainly be of great value, but such a finding is unlikely in the early stages of a cancer

Using the Clinical Data

All the criteria just discussed are purely histological and, difficult though they may be at times to define, they are the best criteria of malignant growth, short of metastasis, that we have Ideally our recognition of "malignancy" in a section should be based on these purely histological criteria alone, and we should be able to answer the question "malignant or non malignant?" or decide that it is unanswerable, by examining the section without knowing anything of the third source of information—the clinical data With one possible exception—that of melanotic growths, where the significance of identical histological appearances possibly does vary with the age of the patient—a verdict of "malignant" or "not malignant" given on histological evidence alone should not be altered by any subsequent learning of the clinical data

It may be objected that a proper and comprehensive opinion on a section cannot be given without full clinical data This is indeed true, but the time for the histopathologist to read the clinical data is after he has assessed the section, not before The almost invariable practice, when given a section, is to read or ask for the clinical data first, then to examine the section and give an opinion This, in my view, is the least profitable and the least accurate way of assessing a section Foreknowledge of the clinical data introduces into our mind a quite ineradicable bias—a bias such that some degree of prejudgment of the section is almost impossible to avoid For example, if a histopathologist is given a section to examine, with the information that it was part of a paranephric mass, associated clinically with paroxysms of hypertension, he is quite unlikely, on finding a somewhat polymorphic slightly glanduliform neoplasm, to say other than that the mass was a phæochromocytoma He may, of course, be correct, but, by learning the site and the clinical associations of the tissue he will have rendered himself virtually incapable of assessing the tissue pattern as a purely histological problem, or of recalling how closely such a growth may resemble a neoplasm of thyroid or parathyroid, or indeed an undifferentiated glandular carcinoma of almost any origin If the same material be examined by a pathologist who, at the outset, intentionally ignores the clinical data, he is likely to argue thus "This is part of a neoplasm whose pattern is not obviously diagnostic If it comes from the region of the adrenal, phæochromocytoma is the likeliest diagnosis, if from around the carotid bifurcation, carotid body tumour is the likeliest If it comes from within or beneath the thyroid, a thyroid or parathyroid adenoma is possible [and he might prefer one rather than the other] If an abdominal lymph-node is the source, secondary glandular carcinoma, of unidentifiable origin, is admissible" Then, and only then, having extracted the maximum information (and the maximum instruction) from the section, he turns to the clinical data and finally, on clinical grounds, narrows down his diagnosis to that one of his histological possibilities which now seems the most appropriate He does this final part, however by virtue not of his histological, but of his clinical, knowledge Similarly, a neuroblastoma, a small cell bronchial carcinoma, or a lymphosarcoma may be more rapidly diagnosed by the pathologist already in possession of clinical data, but, compared with his counterpart who has the habit of examining sections "blind," he will be so much the longer in learning the similarities commonly presented by these tumours Not only is he slower to realise how relatively non specific are many of the tissue patterns which we are apt to accept as diagnostic, but almost inevitably he is also slower to incorporate within his experience such fine differences of pattern as do in fact exist

Now, it clearly matters little to the patient with a frankly malignant neoplasm whether the pattern of his neoplasm resembles that of another frankly malignant neoplasm or not But there are other occasions when identity of histological pattern obviously does matter to the patient very much These are the occasions when the lesion is of "borderline" appearance—occasions when we most need, yet most lack, sharp definition in our criteria of malignancy Here again, the best hope of achieving increased sharpness and specificity in our criteria lies in increasingly frequent practice of "blind" examination of sections

In illustration of this, an instance may be quoted where a histologist, having examined a section "blind," had decided that it showed part of a highly cellular, organising hæmatoma The section itself gave no indication of the site, which was alongside a recently ruptured tendon The section was then shown to two other histologists with the information that the material came from the region of a tendon, and both said, "probably a synoviosarcoma" In the circumstances this was a not unreasonable evaluation of a highly cellular tissue of polymorphic pattern containing clefts and spaces Yet it is doubtful if this diagnosis would have been preferred had they not been biased at the outset by the mention of tendon

The criteria for diagnosis of some examples at least of synoviosarcoma certainly lack specificity and sharp mals There has been some improvement in the last years in the distribution of research, as you describe pril 28), but the balance is still not redressed

M.R C Social Medicine Research Unit,
London Hospital E 1 J N MORRIS.

SIR,—I was much interested in your leader of April 28 id in the admirable paper by Dr Bronte Stewart and s colleagues which appeared with the critical letter of rof Ancel Keys in the same issue I feel that the verage medical man might be somewhat bewildered and onfused by the sudden weight of evidence incriminating ur until recently much praised Western diet for the apid increase in the incidence of coronary-artery disease t is perhaps pertinent, therefore, to recall that when I rst presented some of the fundamental evidences of the ietary theory of coronary heart disease in your columns,[1] hey provoked such adverse criticism that Professor Keys elt obliged to intervene [2] Now, less than two years later, he question is not any more whether the increase of the at calories as a percentage of total ingested calories is esponsible for the increased incidence of coronary athero clerosis, but whether all kind of fats are equally esponsible for it

I was greatly intrigued by some of the "fascinating peculations" of Dr Sinclair (April 7)

I have no doubt that he is on sound ground when he raises he question of essential fatty acids (E F A) with reference to oronary atherosclerosis I am however afraid that he tried o cover too much ground in his letter As Professor Keys ays the idea that deficiency of E F A in the diet may be elated to atherogenesis is not new The vexed question of egetable versus animal fats, especially as far as their influence on hypercholesteremia is concerned, cannot yet be decided with certainty Much work has been done in recent years, but, despite the interesting work of Groen et al [3] and Donath et al [4] on vegetarians, both Hardinge and Stare [5] and Mayer et al [6] in their controlled experiments still came to contradictory results More recent work, however, mainly by Ahrens,[7] Kinsell,[8] and especially Malmros,[9] seems to indicate that not all kinds of vegetable fat have the same lowering effect on serum cholesterol Using corn oil which contains about 57% of linoleic acid, Professor Malmros reduced the blood cholesterol level in 8 patients with familial hypercholesteræmia from 450–500 mg per 100 ml to about 300 mg and kept some of the patients on that level for two months [9] I repeated this experiment, and I did indeed lower the cholesterol level substantially in a healthy person, and in a hypercholesteræmic patient I doubt however, whether our patients will be prepared to face this ordeal unless we can find less repulsive carriers of E F.A Dr Sinclair's observation [10] on increased permeability, and his emphasis on the link with vitamin B_6, might help in the explanation of some of these results, although to prove any, even relative, deficiency of E F.A would need a great deal of additional research

I quite agree with you, Sir, that the great importance of the admirable work of the Cape Town group lies in the assumption that any dietary factor which raises, or lowers, the β lipoprotein level in the blood will also raise or lower the liability to myocardial infarction Incidentally this assumption, by implication, was clearly expressed several years ago by others [11] [12] I am, however, much more impressed by the systematic and careful work of Dr Bronte Stewart and his colleagues in following up the fluctuation of blood-lipids after feeding "on many occasions malodorous oils" for up to 172 days Furthermore, they are most cautious in the interpretation of their results Unfortunately balance studies of fæcal fats have been only sporadically carried out so far, and I am looking forward to seeing the results of more detailed studies, as promised in their paper, for the following reason

According to the authors the physical activity of the volunteers was minimal throughout the study Their fig 1 indicates that a male Bantu, aged 37, with a body-weight of approximately 140 lb , having consumed as much as about 2200–2300 calories daily, lost around 7–8 lb of weight in seven weeks Another male Bantu, aged 65, with an initial body weight of only 110 lb (figs 2 and 7) on a daily calorie intake of about 2300 lost weight in the first month and regained his lost weight on an average daily intake of about 2600 calories in the second month , he gained afterwards slowly less than 5 lb in weight in the following two months on a 2500–3000 calorie diet, and gained again less than 5 lb in weight in the fifth and sixth months averaging about 3000 calories daily (fig 7) Thus 65 year old man was certainly grossly overfed with 50–60 calories per kg body-weight on minimal physical activity, and gained only about 8 lb in six months These two weight curves, which can be read only approximately, strongly suggest that a considerable part of the ingested fats was not fully absorbed and utilised If this assumption is correct, the fat calories of these volunteers were in reality considerably lower than the calculated 36%, 45%, and 60–70% It may also be of some interest that most of the weight gained by the 65 year old Bantu coincided with the two periods when ten eggs were added daily to his diet I am confident that the Cape Town workers will be able to clarify these points soon

We have to keep in mind that the dietary theory of atherogenesis, as it stands at present, was only elaborated in the past few years, and I fully agree with you that more research is urgently needed and that in this type of research the unit of time is the decade But the death-roll from coronary-artery disease is still rapidly increasing Are we going to wait for another decade to take the appropriate measures ? Whilst the elucidation of the influence of E F.A on atherogenesis appears to be, at this moment at least, as important as that of the sex hormones,[12] [13] are we going to condemn our patients to substitute E F A for butter and bacon or demasculinise them with female hormones ? I myself, have had my share of corn and wheat germ oil, and, like Professor Keys,[2] I am convinced that, unless the E F A can be made much more palatable (without hydrogenation), most patients in this country will prefer a diet substantially reduced in those fats which they are used to (or which they like) In other conditions it has been shown in long term observations that such diets work quite satisfactorily in practice [14]

London W 1 Z A LEITNER

SIR,—I am sure I am not alone among public-health medical officers, now liberated from preoccupation with infection and gravely concerned at the ravages of degenerative disease, in regarding the last few issues of *The Lancet* as momentous

First we are treated to Dr Sinclair's fascinating postulations on the relationship of fats and disease This is closely followed by the interlocking findings in the publication of Dr Bronte-Stewart and his colleagues and your own thoughtful commentary in the same issue

Sinclair's work is evidently continuing, but it appears that he has been moved to issue what amounts to an interim report in a genuine endeavour to assist in halting us on the alarming and slippery slope of premature degeneration lesions of quite the same histological pattern, and present for the same length of time, do not A granulosa cell tumour which behaves as a carcinoma may be histologically indistinguishable from one that does not, and a similarly unpredictable future is associated with carcinoid tumours and with occasional melanotic growths The fleshy, spindle cell sarcomas, of whatever type, especially those in the subcutaneous region, form another tumour type whose future behaviour is far from predictable, some recur repeatedly and finally metastasise, others of apparently the same histological appearance do not Retained placental tissue provides a good example of this kind of difficulty Two excised uteri may show foci of persisting, hyperplastic trophoblast of apparently identical type, yet one patient will die of chorionepithelioma, and the other live Quite similar tissue may be found in uterine curettings from patients who have no subsequent hysterectomy and yet survive There is little difficulty in finding evidence of atypical cell growth in such retained trophoblast—the trophoblast may consist of little else but atypical cells—or in finding evidence of invasion, possibly on a grand scale The histopathologist's problem is that there is no dependable correlation between these appearances and the later occurrence of metastases (Park and Lees 1950) The same lack of correlation applies in varying degree to the other neoplasms in this group, and for this reason accurate figures for incidence and curability are again extremely difficult to obtain

“ BORDERLINE ” CASES

The third group of tumours comprises the so called borderline cases—those cases where the surgeon wants an answer to the question, Has this growth crossed the borderline to malignancy ? It is very likely that there is no such definite borderline, but the pathologist will remember that the surgeon nearly always has to act as if there were

This borderline group is the main cause of worry in the diagnosis of biopsy material When the pathologist uses the term “ difficult ” to describe these cases, he is not referring so much to purely histological difficulties (he can still recognise the various tissue components, and their arrangement) as to the lack of available knowledge of the clinical behaviour to be expected with such histological appearances—in other words, to a low level of clinical correlation In these circumstances he cannot give his diagnosis with the same degree of confidence as in the straightforward group nor can this be expected of him

Here we find ourselves in conflict with scientific discipline For *scientific* purposes, remembering our obligation to provide as accurate data as we can for cancer study as a whole, we should, if we feel the evidence in favour of a diagnosis of malignancy to be inadequate, say that a diagnosis of cancer cannot be given For *practical* purposes, since the welfare of the patient is in the balance, the scientific outlook has to be put on one side, and a diagnosis of cancer made if there is even a moderate degree of suspicion of malignancy The difference between diagnosis for these two purposes can be reconciled by making the reservation that though, in the interests of the patient, a diagnosis of cancer has to be made, the case very possibly was not one of cancer at all in other words, to quote from an earlier discussion of this matter, “ it is legitimate to treat a patient because he might have cancer but not legitimate always to assume that if he recovers he necessarily did have cancer ” (Park and Lees 1955)

Summary and Conclusions

In all but clinically manifest cases, surgeons and radiotherapists are dependent for their diagnosis of cancer upon the pathologist It is obvious, therefore, that if comparisons of different forms of treatment or of incidence of cancer are to be valid, the pathological diagnoses on which they depend must be accurate It has been pointed out that, even under optimum conditions, histological assessment of malignancy is far from absolute In the case of early cancer, histological criteria of diagnosis are even less satisfactory, and of lower practical value than pathologists would like In such cases there may be quite legitimate differences in interpretation of the histology, and when this happens figures of incidence of early cancer will vary correspondingly

The property of invasiveness, on whose presence or absence depends frequently the diagnosis of “ malignant ” or “ not malignant,” is particularly difficult to define, and therefore to recognise, in its early stages indeed, in an attempt at its definition, I would go so far as to suggest, and not facetiously, that an abnormal overgrowth of cells should be regarded as showing invasion only if it shows what *every* histopathologist would say *was* invasion

Pathologists should, by all means, persuade the clinician to provide them with as much in the way of clinical data as he can, informing him that, usually, the more help he gives them, the more they can give him I would, however, suggest that the habit of always examining sections first, and reading the clinical data afterwards, is a valuable one It should help to sharpen and clarify diagnostic criteria at that stage of cancer where we most need, yet most lack, sure definition—the early stage

It has been shown that a diagnosis of cancer for practical purposes may at times, in borderline cases particularly, be inescapable, but that it is legitimate for scientific purposes to have reservations about the accuracy of such a diagnosis, and to take this fact into account in the retrospective analysis of data

The term “ histologically proved,” when applied to cancer, is admissible only if “ proved ” is used in its original and now almost obsolete sense of “ tried, tested, or assessed ” Its equation with “ proof ” in the legal sense, with the implication that certain objectively defined, specific criteria have been satisfied, is not justifiable

I am most grateful to Prof A C Lendrum for helpful comments during preparation of the script for publication

URINARY EXCRETION OF ŒSTROGENS DURING PREGNANCY, LACTATION, AND THE RE-ESTABLISHMENT OF MENSTRUATION

J B Brown
M Sc N Z , Ph D Edin

From the Clinical Endocrinology Research Unit (Medical Research Council), University of Edinburgh

Few reliable figures are available for the urinary excretion of œstriol, œstrone, and œstradiol-17β during pregnancy and lactation Most of the published figures for early pregnancy and lactation were for total œstrogens, and many were obtained by semi quantitative bio assay methods (Pedersen Bjergaard and Pedersen Bjergaard 1948, Venning 1948, Jayle and Crepy 1952) Cohen, Marrian, and Watson (1935), using colorimetry, were the first to determine the urinary excretion of œstrogens during the last 6 months of pregnancy they showed that œstriol is quantitatively the most important urinary œstrogen during pregnancy, and that the amounts

BREAST CHANGES IN FIBROCYSTIC DISEASE OF THE PANCREAS

SIR,—The letter of Dr Stroud and Dr Heppleston (April 21) raises some interesting points I have recently studied a post mortem series of breasts, gonads, and endocrines at the Royal Hospital for Sick Children, Glasgow, and agree that the histological appearance in their first case is a not infrequent variant of physiological neonatal mammary hypertrophy I interpret this appearance of dilatation of ducts lined by a flattened epithelium as an involutional change in a duct ectasia produced by considerable secretion in the active phase of *Hexenmilch* production Sometimes this appearance is seen in conjunction with the more normal picture of hyperplastic columnar epithelium, and in the latter I have observed vacuolation of the free border of the cells and passage of small eosinophilic globules (stainable by the periodic-acid/Schiff method) into the lumen of the dilated ducts (see figure) I have noted moderate to severe duct dilatation in 10 infants up to the age of 2 weeks of 65 such cases examined, and in a further 7 children under 1 year of age of 68 such cases examined It is therefore not infrequent 1 of these patients, a 12-week old female, died of mucoviscidosis and staphylococcal bronchopneumonia, having been treated with aureomycin and chloramphenicol

In my series physiological hypertrophy of the breast is an almost invariable finding in the full term neonatal infant and may be accompanied by changes in the vaginal epithelium, ovaries, and prostate This condition is less frequently seen in the premature infant, where the mammary ducts tend to be of solid, cord-like type Regression usually begins in a few weeks but the condition may persist for several months with duct dilatation more obvious than epithelial hypertrophy That hormonal effects may continue to be produced in childhood is suggested by my finding of follicular ovarian activity, endometrial mitoses, and active budding of the mammary ducts of a girl aged 7 years who died of hepatitis and cirrhosis It is well known that liver disease in the adult male may lead to failure to break down œstrogens and result in gynæcomastia, prostatic hypertrophy, and testicular atrophy

In addition to the case of mucoviscidosis mentioned above I have examined the breasts of a further 5 such children, and none showed significant histological abnormality of the breast or sweat-glands of the skin of the breast Of these cases, 1 died at the age of 1 day and another at 3 days and neither had antibiotic therapy A 3rd, who died with bronchopneumonia at the age of 4 months, had been treated with aureomycin, streptomycin, and penicillin, A further 2 cases each died at the age of 21 months with purulent pulmonary infection, each having been treated with penicillin, chloramphenicol, and oxytetracycline, while one also had aureomycin

It would therefore seem that breast changes are at any rate not invariable accompaniments of the mucoviscidosis syndrome Nevertheless the suggestion that antibiotic treatment may be responsible for mammary enlargement is worthy of further study

PROGRESSIVE EXOPHTHALMOS

SIR,—Mr Rowbotham and Mr Clarke (April 14) mention radiotherapy in the treatment of this condition, but express the opinion that it is not justifiable to irradiate the pituitary gland and neighbouring structures, although they do not define exactly what dangers they anticipate from such treatment

In the 30 cases which they cite, operated on by their own method of orbital decompression, exophthalmos was relieved in every case, and no eyes were lost However, orbital decompression, at least when carried out by the usual modification of Naffziger's method, does not always save the patient's eyes

It is only in those severe and rapidly progressive cases, aptly termed malignant exophthalmos, that there is acute danger to vision from papillœdema, keratitis, and perforation of the globe In the more chronic progressive exophthalmos, whether accompanied by thyrotoxic symptoms or not, the condition runs a much more benign course, and there is seldom any danger to vision, although ophthalmoplegia, once it has developed, is usually irreversible Dr Arthur Jones [1] cites a case of malignant exophthalmos in which, despite bilateral orbital decompression, perforation of the right eye occurred, necessitating enucleation Subsequently orbital radiotherapy was given, and led to rapid regression of œdema of both orbits and of the proptosis of the remaining eye, the danger to which was averted The improvement appeared to be permanent

The following case may be of interest ·

A tin worker aged 48, had partial thyroidectomy in 1951 for toxic goitre Three weeks after operation pronounced proptosis of the right eye developed A few weeks later the left eye became affected also In August, 1951, left tarsorrhaphy was performed Owing to increasing orbital œdema and exophthalmos, in November, 1951, he underwent bilateral orbital decompression This failed, however, to save the right eye, which later perforated and had to be enucleated In May, 1952, he was referred to me The left eye was much proptosed, with œdema of lids, and great tension could be felt in the orbital tissue and globe The tissues of the socket of the right eye and right eyelids were grossly œdematous also The patient was in acute discomfort, with severe frontal headaches, and he was extremely anxious about the possible loss of his remaining eye The vision in this was not seriously impaired, but it seemed to be straining against the protective tarsorrhaphy, like a hound on the leash In May, 1952, both orbits were irradiated to a dose of 500r There was symptomatic relief, but the alarming tension and proptosis of the left eye remained In January, 1953, it was decided *to irradiate the pituitary gland* A *dose of 2500r* was delivered in three weeks Within a few weeks the condition was obviously improved the left eye was much less tense, watering had ceased, and the œdema of the orbit was subsiding, and he lost all his previously agonising headaches

During the past three years, his condition has remained satisfactory, although there is still some proptosis, and it was felt wise to retain the tarsorrhaphy (with a small central hole through which he sees quite well) The subjective relief has been most striking

In this case orbital decompression failed to save one eye, and the other one might well have been lost too if the disease had not been arrested and partly reversed by radiotherapy Although Jones, and Sosman in described by Brown (1955a), modified, as follows, for urines containing larger amounts of œstrogens than could be satisfactorily measured by the original method

---

[1] Jones, A *Brit J Radiol* 1951, 24, 637

The 24 hour urine volumes were diluted to 2500 ml with water, according to the stage of pregnancy, 200, 100, 50, 20, or 10 ml portions of this were used for each determination, and complete specimens of the œstriol fraction, or aliquots of $^1/_2$, $^1/_5$, or $^1/_{20}$ were taken for colour development so that the final œstriol, œstrone, and œstradiol 17β colours were within the convenient range for colorimetry Specimens of urine of less than 100 ml were diluted to 100 ml with water before acid hydrolysis, and half the volumes of hydrochloric acid, ether, and carbonate solutions recommended in the original method were used After the evaporation stage, the original procedure was unaltered, but if necessary, portions of the œstriol eluates from the chromatogram columns were taken for colour development

The loss of œstrogens during acid hydrolysis (Brown 1955a) is less evident when the urine is dilute than when it is concentrated, and is negligible in late pregnancy when the urine is diluted five times or more before hydrolysis To show that the method used in this investigation is reliable at the œstrogen levels encountered in late pregnancy, recovery experiments were performed in which 200 µg of œstriol, 20 µg of œstrone and 10 µg of œstradiol 17β were added to 10 ml of male urine diluted to 100 ml with water *before* acid hydrolysis these amounts are equivalent to daily excretions of 50 mg of œstriol, 5 mg of œstrone, and 2 5 mg of œstradiol 17β In twelve such experiments, the mean percentage recoveries with their standard deviations were œstriol, 81 ± 3, œstrone, 83 ± 1 4, and œstradiol, 81 ± 4—which are within the ranges claimed for the method

Results

The results obtained from subjects 7 and 8 over a period which includes a complete menstrual cycle and the cycle in which pregnancy started are shown in figs 1 and 2 In both women the urinary œstrogen levels were very similar in the two cycles up to about the 24th days—showing the ovulation peaks and the subsequent luteal rise In the first cycle the œstrogen levels then decreased before the onset of menstruation, but in the second cycle, when pregnancy had occurred, they continued to increase, and they began to increase rapidly about 7 weeks after the last menstrual period Subject 7 had nausea at this time

The results from the four subjects throughout their pregnancies are shown in fig 3 on a logarithmic scale Those for subject 8 are also shown for a week after delivery There was a rapid rise in the urinary levels of the three œstrogens throughout pregnancy, greatest between the 6th and 20th weeks The œstrone and œstradiol levels at labour were 100 times higher than those during the luteal phase of the menstrual cycle, the œstradiol levels being about one third of the œstrone levels The urinary œstriol levels rose approximately 1000 fold during this time The results obtained during the last weeks of pregnancy are shown in more detail in the accompanying table

EXCRETION OF ŒSTRIOL, ŒSTRONE, AND ŒSTRADIOL-17β DURING LATE PREGNANCY EXPRESSED AS MG PER 24 HOUR SPECIMENS OF URINE

Subject	Type of œstrogen	Weeks before delivery			Days before delivery						
		4	3	2	7	6	5	4	3	2	1
7	Œstriol Œstrone Œstradiol	16 0 75 0 30	17 0 70 0 28	19 0 75 0 40	22 0 93 0 38						20 0 9 0 38
8	Œstriol Œstrone Œstradiol	31 1 5 0 60	31 1 5 0 58	39 1 7 0 65	35 1 6 0 60	34 1 5 0 63	36 1 5 0 64	41 1 7 0 73	40 1 7 0 70	36 1 5 0 60	41 1 0 68
9	Œstriol Œstrone Œstradiol	24 1 4 0 38	22 1 3 0 38	35 1 8 0 57	28 1 2 0 48	30 1 2 0 46	23 1 0 0 38	30 1 0 0 40	24 0 93 0 35	25 0 93 0 30	21 0 93 0 33
10	Œstriol Œstrone Œstradiol	41 0 29 0 73	33 2 1 0 83	36 1 7 0 70	31 1 6 0 63	36 1 8 0 73	39 1 5 0 70	39 1 8 0 85	30 1 4 0 60	41 2 1 0 90	

Subject 8

During labour, which lasted 3 hours, the urinary excretion calculated on a 24 hour basis was 44 mg of œstriol, 1 7 mg of œstrone, and 0 85 mg of œstradiol 17β After delivery, the urinary œstrogen levels fell rapidly In the case of œstrone and œstradiol-17β there was a linear relationship between the logarithm of the amounts excreted and the time after delivery, and normal non pregnancy levels were reached within 5 days In the case of œstriol this linear relationship did not apply so closely, and normal non pregnancy levels were not reached until 25 days after delivery (fig 4) Levels were low during lactation and reached a minimum (œstriol 1 0 µg, œstrone 3 µg, œstradiol 0 µg per 24 hours) at the time when lactation became inadequate and suckling was discontinued Thereafter the amounts increased slowly

There was slight vaginal bleeding on the 78th and on the 84th days after delivery when the œstriol and œstrone levels were both approximately 7 µg per day Soon

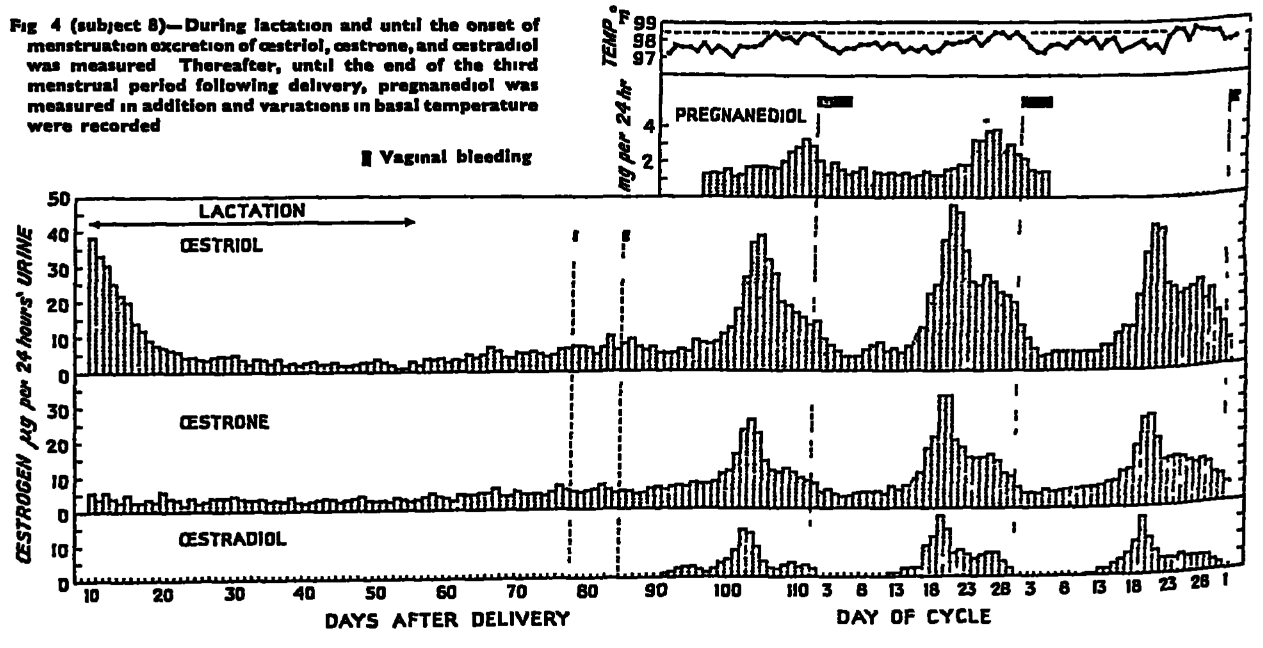

Fig 4 (subject 8)—During lactation and until the onset of menstruation excretion of œstriol, œstrone, and œstradiol was measured Thereafter, until the end of the third menstrual period following delivery, pregnanediol was measured in addition and variations in basal temperature were recorded

NON-DISCIPLINARY ERASURE FROM THE REGISTER

SIR,—It is not generally realised that under the Medical Acts 1858–1950 the name of a registered medical practitioner may be lawfully erased from the Medical Register if he fails to reply to an inquiry from the registrar of the General Medical Council concerning his address and/or possible retirement from active practice Restoration of a name so erased is a costly and tiresome business Application must be supported by an affidavit and at least two certificates of identity and good character together with a fee

Medical defence societies are seriously perturbed at the number of their members whose names are so erased Not only are they unwittingly and illegally engaging in practice in the mistaken belief that they are registered medical practitioners, but they may find themselves removed from membership of their defence society, which would prove a serious matter if they became involved in threatened or actual litigation

It therefore behoves every medical practitioner from time to time to satisfy himself that his name appears in the Medical Register and to furnish an address at which he can be reached by communications from the General Medical Council or from the defence societies In their own interests, both present and future, practitioners are strongly urged to give attention to this matter immediately and thereby ensure that they are not acting illegally or deprived of the necessary legal advice and protection should medicolegal trouble arise in the conduct of their professional duties

JOHN COLLINSON

FŒTAL MORTALITY IN PREGNANT DIABETICS

SIR,—I was interested to note the low fœtal loss in pregnant diabetics reported last week by Dr Pedersen and Professor Brandstrup, particularly because these authors seem likely to be able to assist in confirming the correctness of my theory of the cause of eclampsia[3]

In my paper I suggested that toxæmia and eclampsia originated from damage to the syncytium, produced by maternal opposition to the entry of hormones manufactured by a foreign or transplacental source (a fœtus or mole), after the mother had become intolerant to the presence or activity of these invading hormones This maternal opposition to the entry of fœtal hormones would, I suggested, mean that with the onset of toxæmia (marked first by digital œdema, and later by hypertension and albuminuria) the entry of fœtal insulin into the diabetic mother would diminish, or be cut off, and that her blood sugar would rise and her need for parenteral insulin would increase Conversely, in the absence of toxæmia fœtal insulin would continue to enter the mother freely, and reduce her requirements of parenteral insulin until term

The low fœtal loss reported by Dr Pedersen and Professor Brandstrup is attributed by them "either to the lowering of the mother's blood-sugar level for a long time, or to unknown factors favourably influenced by strict control of the diabetes" during the last eight weeks—i e, those weeks in which toxæmia commonly occurs Their conclusion supports my theory, and I hope that they may be able to supply further details concerning insulin requirements and blood sugar findings in the presence and absence of toxæmia, which will further assist in proving my thesis

CLUBS FOR THE HARD OF HEARING

SIR,—We shall be grateful if you will allow us the use of your columns to point out that persons who are suffering in any degree from loss of hearing can derive great benefit from joining a club for the hard of hearing There are some two hundred of these clubs in Great Britain and Northern Ireland affiliated to the British Association of the Hard of Hearing

The suffering entailed by loss of hearing is largely psychological and is due to loneliness and the frustration of the social instincts It can be acute Besides purely social activities, the clubs give opportunities for lip-reading practice As they are almost wholly run by people who are themselves hard of hearing, they also offer scope for organisational talents which are often blocked by inability to hear on normal committees The wider work of county leagues and of the association itself gives an outlet for all degrees of ability

Within the clubs, experienced hearing-aid users can often advise novices on the practical use of an aid, thus saving unnecessary calls on the clinics

There is no fear that the clubs will lead to segregation of the hard of hearing On the contrary, many members who formerly shrank from normal contacts have been brought back to a full participation in the life of the community

Our honorary secretary, whose address is 64, Liverpool Road, Chester, will at all times be pleased to answer inquiries and to supply helpful pamphlets

ACUTE AND LATENT PORPHYRIA

SIR,—Dr Whittaker and Mr Whitehead suggest (April 28) that barbiturates may be related more to neurological complications than to the precipitation of an acute attack of porphyria That this is not always so is shown by the following case of acute porphyria

A housewife, aged 43, was admitted in 1953 with a history of grand mal epilepsy for twenty seven years, for which she had received phenobarbitone for nine months twenty years previously, and again for two months before admission Three weeks before admission she had had intermittent colicky abdominal pain followed in a few days by paralysis of both legs Phenobarbitone was discontinued a week before admission

Her father had died three months previously The cause of death was said to be cardiac failure During the last five years he had been having attacks of abdominal pain accompanied by the passage of dark red urine about every six months

On admission the patient was extremely ill, with signs of peripheral circulatory failure and flaccid paralysis of both legs Repeated examination of the urine showed no porphobilinogen Her condition gradually improved, and four weeks after admission she was given a test dose of amylobarbitone sodium gr 3 About seven hours later she complained of severe colicky abdominal pain and a specimen of urine collected shortly afterwards was found to contain porphobilinogen (Watson Schwartz test) This was confirmed by spectroscopy and examination of the urine under ultra-violet light By the following day she was none the worse for her experience

It would seem from this case that barbiturates can occasionally precipitate an attack of acute porphyria

ANÆSTHESIA FOR OPERATIVE OBSTETRICS

VALUE OF CUFFED ENDOTRACHEAL TUBE

David J Coleman
M B Lond, F F A R C S, D A
SENIOR REGISTRAR

Brian L Day
M A, B M Oxfd, F F A R C S
REGISTRAR

DEPARTMENT OF ANÆSTHETICS, ST GEORGE'S HOSPITAL, LONDON

The dangers of administering a general anæsthetic to a woman in labour or in whom labour is imminent have recently received considerable attention, particularly from obstetricians (Wrigley et al 1955) Aspiration of gastric contents during or immediately after anæsthesia is a serious hazard We seek to show here how this may be averted by the use of a cuffed endotracheal tube

Mortality and Morbidity

The main cause of maternal mortality resulting from general anæsthesia for obstetric surgery is regurgitation of gastric contents with subsequent aspiration, and, with the reduction of the maternal mortality from other causes, this has assumed a greater significance

In 1949 Sir William Gilliatt reported that of 55 maternal deaths associated with 34,146 deliveries at twenty-three hospitals, 3 had been due to aspiration of vomit under general anæsthesia Gilliatt stated that "these are deaths which should not have occurred," and he stressed the importance of a properly trained anæsthetist attending women in labour

Jeffcoate (1953), reviewing the records of the Liverpool Maternity Hospital for the years 1935–50, found that of 6 maternal deaths 3 had been due to the aspiration of vomit He stated that "the greatest danger of forceps delivery under general anæsthesia at the present time is anæsthesia"

Parker (1954) described 7 cases of aspiration of vomit at the Birmingham Maternity Hospital, 6 of the patients died 5 of the cases occurred in a total of 18,524 deliveries in 1943–52

In the U S A Merrill and Hingson (1953) surveyed the experience of 183 hospitals in 1945–49, and found that there had been 59 maternal deaths due to aspiration of vomit from a total of 2,503,921 births

Merrill and Hingson estimated that inhalation of vomit accounted for between 1 5 and 2 5% of maternal deaths in the whole of the U S A At a recent meeting at the Royal Society of Medicine (Wrigley et al 1955) it was considered probable that the figure for *hospital* practice in this country was higher Besides maternal mortality, maternal morbidity and fœtal mortality due to anæsthesia must be taken into account

Hartzell and Mininger (1946) recorded 20 cases of bronchopneumonia due to the aspiration of vomit under ether anæsthesia, while Davis and Gready (1946) reported 45 "aspiration accidents," 8 of which were serious Presumably many more cases occur, but since recovery is complete they are rarely recorded (Merrill and Hingson 1953 McKelvey and Freeman 1954)

As regards infant mortality little is recorded Anoxia brought about by vomiting must weigh heavily against the fœtus, and it seems reasonable to assume that in some cases it proves fatal

The Lancet (1955), summarising the present position, noted "There has been some uneasiness about an apparent increase in the maternal deaths due to anæsthesia but this may well be only a relative increase, brought about by a fall in the number of deaths from other causes" Whatever the exact position, there appears to be a need to improve anæsthesia for the woman in labour

The Problem

Labour may last for hours or days, and at any moment it may be necessary to induce anæsthesia Thus it is impossible both to feed the patient and to prepare her adequately, by modern standards, for operation A compromise has to be found, and it is now the practice to give women in labour an easily assimilated diet consisting mainly of fluid and glucose The glucose administered should be isotonic, Morton and Wylie (1951) have drawn attention to the action of hypertonic glucose in slowing gastric emptying and increasing the volume of fluid in the stomach During labour the gastric emptying-time is prolonged, and Hirscheimer et al (1938) showed that out of 10 primigravidæ in labour 2 had emptying times of up to nine hours In our experience this may often be extended up to eighteen hours, the factors responsible are the presence of a large mass in the abdomen, and the effects of fear and of painful uterine contractions Moreover, the stomach may become dilated, especially in long labours (Greenhill 1943) From the anæsthetist's point of view it is wise to *suppose that the stomach of a woman in labour is never* empty

The obstetrical requirements of anæsthesia are good oxygenation, a light plane of anæsthesia, and moderate muscular relaxation When a conventional anæsthetic sequence (i e, nitrous oxide and oxygen with trichlorethylene, ether, or cyclopropane) is being used, an error of judgment by the anæsthetist or a sudden increase of stimulus by the obstetrician may cause laryngeal spasm, lightening of anæsthesia, vomiting, obstruction to the airway, and anoxia Again, a stormy induction with pronounced excitement and a slow descent through the second stage of anæsthesia will predispose to vomiting To prevent these complications it is essential that the airway be completely under the control of the anæsthetist, and to ensure this a cuffed endotracheal tube must be used

Management

The anæsthetic management of the pregnant woman should begin in the antenatal period when the patient should attend classes conducted by the anæsthetist At these meetings an attempt is made to dispel latent fears of the unknown and of pain by a simple account of the analgesic procedure in labour

After admission to hospital an easily assimilated diet should be given It has been suggested that gastric lavage should be attempted before inducing anæsthesia (DeLee and Greenhill 1943), and that if this fails anæsthesia should be carried *to* the stage of complete sensory loss, and the gastric lavage then repeated effectively In our experience, however, attempting to pass a Ryle's or œsophageal tube on a woman in labour increases her fear and distress, commonly the quantity of fluid and debris recovered is small (Hirscheimer et al 1938), and the Ryle's tube may then be returned on the crest of the vomitus wave We do not attempt to aspirate the stomach unless the patient is *actively* vomiting at the time of induction It is then essential to use a large bore œsophageal tube

There has been considerable discussion as to the ideal position of the patient for a forceps delivery *Those* performing their deliveries with the patient in the left lateral position have been quick to indicate the advantages of this position to the anæsthetist, should vomiting occur Once intubation has been achieved, the position adopted is of little importance to the anæsthetist, and of course if cæsarean section is to be undertaken there is no choice of position

From the anæsthetist's point of view the important position is that used during the induction of anæsthesia If vomiting is expected the Trendelenburg position is usually chosen The reverse Trendelenburg position,

FUND FOR TUBERCULOUS WOMEN

Mr W H **Townsend**, of the Margaret de Sousa Deiro Fund, writes

This Fund exists for the treatment and relief of women who, normally supporting themselves by their own exertions, are temporarily incapacitated by pulmonary tuberculosis There are grants to cover the cost of treatment, when this cannot be carried out in suitable conditions under the National Health Service, and grants towards convalescent holidays following institutional treatment In approved cases the trustees also give financial assistance for rehabilitation, when part-time work yields an inadequate living wage By its constitution the Fund cannot assist chronic cases where there is no prospect of return to employment Further information can be obtained from the trustees at 1, New Court, Carey Street, Lincoln's Inn, London, W C 2

Parliament

The Guillebaud Report

Mr R H **Turton**, the Minister of Health, in opening on May 7 a debate on the Guillebaud report described it as a "welcome vindication of the National Health Service as it now exists" The report made clear that economy and efficiency had increased since the service began in 1948 Thus in real terms the increase in the gross cost of the service between 1949 and 1954 was small —only £30 million out of a total of £400 million— and during these years the service had been substantially improved and extended.

Perhaps the greatest problem of the service, he continued, was the tripartite division of the administrative structure, and the committee agreed that cooperation between the different branches of the service, and even within them, had not yet been fully attained The Government, Mr Turton said, accepted that there should not at this time be any transfer to other authorities of responsibility for hospital or general-practitioner services, any creation of new central or local ad-hoc authorities as the recipients of particular functions, any changes in regional-hospital-board areas or in their methods of appointment, or any transfer to those boards of responsibility for teaching hospitals in England and Wales, or any transfer of dental-clinic services from local authorities to the central health departments The acceptance of these broad principles did not, however, cover the whole ground, and it was indeed dependent on certain minor adjustments of practice, if not of organisation In the hospital service, for instance, the committee had suggested that it should be made clear that the regional hospital boards were responsible for exercising a general oversight and supervision over the administration of the hospital service in their region The Government accepted this principle, but Mr Turton wished to make it clear that this did not mean that the R H B s should set the H.M.C s (or for that matter the Minister the R H.B) in a strait-jacket of prior approvals The conception was rather one of review—and, if necessary, rebuke—after the event, and not of reference upwards beforehand

It was in the home health and preventive services, Mr Turton thought, that the tripartite administrative structure raised most problems, and our first objective must be "to place at the disposal of the patient in his home, equally with the patient in hospital a coordinated team acting under the clinical guidance of his personal medical attendant" This would call for the closest cooperation between the general practitioners and the local health authorities It should be the aim of the home team, which must include welfare as well as health workers, to keep out of hospital, including mental hospitals, all patients who could equally well be treated at home In his view health and welfare were so closely linked that in the domiciliary field at least they ought to be administered as one

Turning to finance Mr Turton recalled that the Guillebaud Committee had suggested £30 million a year as a desirable rate of capital expenditure for the hospital service for the coming seven years The programme for hospital building announced last year, providing £17½ million for new major projects and £13 million for capital expenditure, was a major step in the direction proposed by the committee It would not be affected by the cuts in capital expenditure The committee's recommendation that charges for dental treatment and spectacles should be reduced raised the question of priorities between the different parts of the service and must be reserved for further study

However the service was organised, Mr Turton concluded, so long as unlimited financial resources were not available, questions of priority would arise In his own mind the three needs which could claim precedence were hospital accommodation, the mental-health services, and old people

Dr **Edith Summerskill** agreed with the committee and the Minister that no major administrative changes should be made in the service anyhow at this stage The proposal to restore certain kinds of hospitals to the local health authorities would, in her view, be a retrograde step because it would establish a central and a local hospital authority She would like to see closer collaboration between the local authorities and the general-practitioner service The conditions of service of the practitioner should bear a closer resemblance to those of the medical officer of health The salaried medical officer's approach to medicine, with the emphasis on prevention, had been dissimilar to that of the general practitioner occupied with the curative side Unfortunately the N H S still made the doctor dependent on fees—there were still capitation fees—and that gap between these two doctors, working in two different medical worlds, was unfortunately not made smaller The time was coming when we must consider the best means of remunerating the general practitioner

She was disappointed that the Minister had not accepted any of the financial recommendations of the committee 45% of our hospitals were built before 1891 The capital expenditure on hospitals was three times as high in 1938–39 as it was in 1952–53 The teaching hospitals, she thought, should be integrated with the regional hospital boards It was an anachronism for them to be autonomous The splendid isolation of the teaching hospitals tended to introduce a snob element into the health service which militated against cooperation and the closing of the human gap

The shilling prescription charge was, she held, unjustifiable It had reduced our huge medicine bill of £46 million by £4 million It deterred not the hypochondriacs or the better off but the poorest in the community who should have no financial barrier between them and the doctor With the expensive high-pressure salesmanship of the drug houses, was it any wonder that the Minister had to keep on asking for more money for proprietary drugs? She found it difficult to reconcile the colossal sum spent on drugs, and the Minister's weak attitude towards it, with the decision to cut the milk-supplies to the under-5s in the nursery

Sir **Frederick Messer** regretted that the Guillebaud report had not said more about preventive service In his view it was worth considering whether the maternity and child-welfare services and domiciliary services should not be transferred from the county councils to the large boroughs Mr **John Baird** suggested that, in considering priorities, we should remember that the N H S was in fact a money-saving service Sir **Hugh Linstead** believed that doctors did not need Ministerial protection against the advertising methods of the drug firms

Colonel **Malcolm Stoddart-Scott** thought that the Guillebaud report confirmed that the N H S would become in the very near future the first priority of our social services He besought the Minister to persuade the Cabinet to spend no less than £50 million a year for the next five years or so on building and modernising hospitals He regretted that the Guillebaud report remained so silent on the needs of mental health and of preventive health and said nothing at all about the development of the industrial health service In his opinion there should be one national health service both for industry and for the civil population

Mr **Arthur Blenkinsop** had been impressed by Professor Titmuss and Mr Abel-Smith's financial survey What hope was there, he asked, of the regular production for the public of information about how the health service was going? As the Guillebaud report showed, the service was not extravagantly run, and he thought that everyone had been influenced to some extent by the aura of unfounded charges The Minister, he thought, had little

A SPECIFIC VIRUS-ANTIBODY FLOCCULATION REACTION WITH POLIOMYELITIS VIRUSES

WILSON SMITH
M D Manc , Dip Bact , F R S

F W SHEFFIELD
M B Lpool

L H LEE
M B Malaya

GILLIAN CHURCHER
M B Lond

From the Department of Bacteriology, University College Hospital Medical School, London

IN a recent publication from this laboratory Belyavin (1956) reported a macroscopically visible flocculation reaction between influenza viruses and their specific antisera His subsequent work, much of it still unpublished, has firmly established the value of the reaction both as a research tool for the investigation of virus structure and strain relationships and as a practical method—simple, rapid, and flexible—for the assay of serum antibodies

The question whether such direct flocculation would take place with other viruses, especially those of a different order of size and possessed of quite different biological characteristics, seemed to us to be of great scientific interest and importance Poliomyelitis viruses were chosen for investigation for the additional reason that a simple in vitro method of typing poliomyelitis viruses and of detecting and assaying antibodies is urgently required , present available methods can be used only in specially equipped laboratories and even there impose severe limitations on the amount of work which can be undertaken because they are so expensive and time consuming The urgency of this need is considered to justify present publication of the results of experiments which are obviously of a preliminary nature but which, nevertheless, show conclusively that poliomyelitis viruses react with homologous serum antibodies to form, under appropriate conditions, easily visible floccules, and that the reaction is type specific We are under no illusions as to the amount of further work needed to establish the full significance of this reaction and to determine the range of its practical applicability, but we believe that it opens up a new line of approach to many outstanding problems of poliomyelitis

Materials and Methods

Poliomyelitis Viruses

Virus strains used were Brunhilde (type 1), Lansing and Y SK (type 2), and Leon (type 3) Seed pools of each were prepared as required and stored at –20°C

Cultivation of Virus

The viruses were propagated in HeLa cell cultures The HeLa cells were grown in the medium recommended by Sheffield and Smith (1956) Small cultures in Sanders bottles were used for the routine passage of virus and for titrating virus, but for the production of flocculating antigens larger cultures in babies' feeding bottles made of 'Pyrex' glass were made to obtain sufficient quantities of virus Each bottle received an inoculum of about 4 × 10^6 HeLa cells which, with medium changes on the 3rd and 5th days of incubation, gave cultures of about 10 × 10^6 cells by the 7th day On the 7th day all medium was removed and the cells were washed thrice with Earle's solution An inoculum of 0 05 ml or 0 10 ml seed virus was added to each bottle followed by 10 ml maintenance medium Incubation was continued at 37°C on a roller drum for a further 48 hours, at which time the virus fluids were harvested Two different maintenance media have been used Parker 199' with 10% rabbit serum , and Earle's solution 85%, 5% solution of lactalbumin hydrolysate 5%, and rabbit serum 10% Both of them have proved satisfactory, though we now prefer the second because of its simplicity

Preparation of Virus Antigens

These were prepared by concentration and purification of virus from the culture fluids Batches of pooled virus fluids were first centrifuged in a horizontal centrifuge at 1500 r p m for 15 minutes to remove gross particles They were then clarified by centrifugation in the 'Spinco Rotor No 21' at 15,000 r p m for 42 minutes This treatment removes much extraneous material without depositing any appreciable quantity of virus From the clarified supernatant fluid virus was deposited by high speed centrifugation for 5 hours in the 'Spinco Rotor No 30' at 30,000 r p m The supernatant fluid containing small molecular constituents of the medium but only negligible amounts of virus was discarded, and the deposited pellet of each tube was resuspended in either 1 0 ml or 0 5 ml of saline solution Tube capacity was 38 5 ml , so the nominal virus concentration factor was either × 38 5 or × 77 Perfectly homogeneous suspension of the material in such small volumes of saline solution, however, was impossible Pooled virus concentrates were therefore given a final clarifying spin in the horizontal centrifuge at 1500 r p m for 15 minutes The resultant suspensions of virus were distinctly opalescent but entirely free from visible particles when viewed in a viewing box with the aid of a hand lens They were used as antigens both for the flocculation experiments and for the immunisation of rabbits They received no treatment for inactivation of the virus, nor was any preservative added

Preparation of Antisera

Rabbits were immunised by intravenous inoculation of the virus concentrates described above Two doses were given with an interval of 14 days Samples of blood were taken at various intervals thereafter Some rabbits were given a third dose of virus after a rest period of several weeks, followed again by bleeding at intervals The adoption of a uniform immunisation schedule was impossible because at that time nothing was known about the immunological responses of rabbits to poliomyelitis viruses , moreover, as the virus concentrates were used as soon as possible after their preparation, the amount of virus contained in each dose was not known until several days later, when the results of titrations in HeLa cell cultures were obtained The full range of sera will be used eventually for a more detailed study of the immunological responses of rabbits , but, for the flocculation experiments, only three of the samples, one against each virus type, were used They were obtained thus

Rabbit no	*Virus antigen*	*Day*	*Inoculation TCD/50 × 10^6*
4/55	Type 1 (Brunhilde)	0	1 60
		14	1 75
		24	Bled
1/56	Type 2 (Lansing)	0	0 003
		14	0 24
		24	Bled
3/56	Type 3 (Leon)	0	0 50
		14	0 63
		51	1 20
		58	Bled

Serum was separated from the clotted blood after overnight storage in the refrigerator, freed from cells by centrifugation, doubly inactivated by two separate heat treatments, each at 56°C for 30 minutes, and stored in the frozen state until required It is not known whether double inactivation is necessary, but it was adopted because of its importance in influenza virus flocculation (Belyavin 1956)

Flocculation Technique

Flocculation tests were done by the standard method of bacterial agglutination 0 3 ml quantities of each reagent, virus antigen and antiserum, were mixed in Dreyer agglutination tubes Dilutions of reagents were evidence from this and other countries to which he refers tends to show that mortality from cancer of the lung is twenty times greater amongst heavy smokers than amongst non-smokers The Government will take such steps as are necessary to ensure that the public are kept informed of all the relevant information as and when it becomes available.

Mr W. D. CHAPMAN While thanking the Minister for at last saying something very forthright on this issue may I first ask him what line of action he will take to inform the public about this danger? Has he in mind something as widespread as the campaign against diphtheria and in favour of diphtheria immunisation, and secondly, will he give us an assurance that the Government will take the initiative in such a campaign and will not leave it simply to the local authorities to do so if they wish?—Mr TURTON. In my view, in the present stage of our knowledge, a national publicity campaign would not be appropriate

Mr. VAUGHAN-MORGAN. Is there any evidence, particularly with regard to pipe-smoking, secondly, is there any evidence from the statistics as to how those who give up smoking are affected?—Mr. TURTON: It would appear that pipe-smokers face a heavier risk than non smokers, but the risk is substantially less than that incurred by heavy cigarette smokers There is some evidence that the risk of contracting cancer of the lung decreases when smoking is given up

Dr. EDITH SUMMERSKILL: In view of the fact that the Minister for the first time is informing the country that tobacco smoke has certain carcinogenic properties and has made an emphatic statement, would he not agree that it was rather unfortunate that this statement came after the statement by eminent authorities on the radio and on television? I understand that a film was even shown in this building last week. Is it not unfortunate that the Minister's statement should follow these statements and not precede them, and in view of the gravity of the present statement, will he say why he will not give us a periodic review of the situation?—Mr TURTON. Whenever any more knowledge becomes available, I shall deem it my duty to put it before the House at once That is what I have done in this case but I must first of all see what has been the increase in knowledge since the last statement made I did tell the House some time ago that two cancer-producing substances had been identified in tobacco smoke

Dr BARNETT STROSS. Will the Minister agree that there is now at least ample evidence to suggest that he should consult the Minister of Education and that all efforts should be made to bring this knowledge before school-leavers, boys and girls, in order that they at least may have some warning as to what may be the result of becoming as addicted to this habit, as so many of us are? Mr. TURTON I have given my decision regarding a national publicity campaign Any matter regarding what is done by the Minister of Education should be addressed to him. Mr ARTHUR BLENKINSOP Surely the Minister will review his statement with regard to a national campaign? Is it not highly important that any information that may become available should be reviewed from time to time?—Mr TURTON I quite agree. I certainly shall review it.

Housing of the Elderly

Replying to a question, Mr DUNCAN SANDYS, Minister of Housing and Local Government, said that he had decided to inquire into the arrangements that were being made for housing elderly persons. His object was to see whether, having regard to the requirements of other sections of the population, old people were receiving a reasonable share of the accommodation provided and whether this was of the kind best suited to their physical needs and financial circumstances. Accordingly, he proposed to ask all local authorities and certain voluntary organisations to send him particulars of what they had done to deal with this problem. While this information was being collected a qualified official of the Ministry would go and see schemes of various kinds in different parts of the country and make a report to him upon them. He also intended to seek the views of the Central Housing Advisory Committee. The problem of housing elderly people was in many respects connected with that of providing for their health and welfare His inquiries would therefore naturally be carried out in close collaboration with the Minister of Health.

Recruitment of Mental Nurses

Replying to a question, Mr TURTON, Minister of Health, said that the basic allowances of new entrant student mental nurses under twenty-one were being increased by amounts varying from £20 to £45 and of those over twenty-one by amounts varying from £80 to £110 per year The discontinuance of dependants' allowances would however mean that student mental nurses with a wife and one child would have these increases reduced by £72 16s. a year.

Replying to a further question, Miss HORNSBY SMITH said that the numbers of new entrants of male student nurses in mental deficiency were in 1954, 140 and in 1955 133, the numbers of readmissions were 34 and 25 respectively The numbers leaving while still students were in 1954, 174 and in 1955, 121

Nurses in Scottish Mental Hospitals

Replying to a question, Mr JAMES STUART said that at Sept 30 1955, the ratio of nurses to patients was less than 1 to 5 in twelve of Scotland's twenty-nine mental hospitals accommodating 42% of all patients in mental hospitals At the same date this ratio was less than 1 to 6 in two of the twelve mental-deficiency institutions, accommodating 18% of all patients in such institutions.

Colour of Milk Bottles

Replying to a question asking what consideration had been given to the deterioration of milk by the use of clear glass bottles, particularly when exposed to light and sun for long periods, Mr HEATHCOAT AMORY, Minister of Agriculture Fisheries and Food, said that there were no regulations about the colour of milk bottles The matter had been considered by the Milk and Milk Products Technical Advisory Committee and they had expressed the view, which he had accepted, that there were no adequate grounds for regulations

Replying to further questions Mr AMORY said he thought that it was true that milk retained its high food value better in coloured than in clear glass bottles Milk could retain its riboflavine and vitamin C content better, both of which suffered from long exposure to the sun. But there were practical considerations which made it difficult to deal with the matter by regulation. One of the considerations in the minds of the advisory committee was that with clear glass bottles purchasers could see more readily whether the milk was relatively clean or not.

Public Health

School Milk

CHANGES in the milk-in-schools scheme are announced. From Sept. 1 free milk will be available for schoolchildren only during term-time, and the limited arrangements for supplying milk at weekends and during the holidays will cease Children in nursery schools now receive $\frac{2}{3}$ pint daily, and those in nursery classes receive $\frac{1}{3}$ pint From Sept 1 all children will receive $\frac{1}{3}$ pint, with the exception of delicate children attending special schools who may be given $\frac{2}{3}$ pint. A saving of about £125,000 a year is expected.

In a circular to local education authorities the Ministry of Education asks that special care be taken in the ordering of milk, pointing out that the excessive purchasing of only 4 bottles in every 100 would involve the Exchequer in an extra expenditure of about £500 000 a year The amount of milk ordered should be based on the number of pupils taking milk regularly, allowing for the usual rate of absences.

From Sept. 1 local education authorities will be responsible for supplying milk to pupils in non-maintained schools as well as maintained schools. The terms under which local education authorities supply milk to non-maintained schools will be determined by agreement between the authority and the proprietor of the school, and should include provision by the proprietor of such information about ordering and consumption as the authority may require. The terms should also include a stipulation that no payment should be made by parents for milk supplied.

Slum Clearance

Speaking at Stoke-on-Trent on May 4 Mr Duncan Sandys Minister of Housing and Local Government, said that during last year some 25,000 slum houses were

TABLE III—CROSS-CHESS-BOARD TITRATIONS OF BRUNHILDE AND LEON REAGENTS

Antigens		Brunhilde serum						Leon serum					
		1/10	1/20	1/40	1/80	1/160	1/320	1/10	1/20	1/40	1/80	1/160	1/320

	1/8	−	−					+	+	+	++	±	−
	1/16	−	−					−	−	−	−	−	−

Final reading at 4 hr. incubation.

from the HeLa cells but may equally well be an indication of an antigenic relationship between poliomyelitis viruses of different types similar to that which has been shown to exist between influenza viruses of types A and B (Smith et al. 1955).

Periodic readings from 30 minutes to the final reading at 4 hours showed progressive development and extension of flocculation with both virus types similar to the development illustrated by table II. In this experiment Leon reagents flocculated more rapidly than Brunhilde and gave a beautiful demonstration of inhibition in the zone of antibody excess in spite of the omission of serum dilutions lower than 1 in 10. Optimal flocculation tubes in each row were clearly recognisable at some stage of the observation period, shifting one tube to the right with each progressive twofold dilution of the antigen. Even so, except for a single tube, flocculation was confined to dilutions of antigen 1 in 8 or less. Also, with Leon reagents, very little extension of flocculation occurred after 2 hours, whereas with Brunhilde reagents the flocculation area at 2 hours was less than half that shown at 4 hours.

Flocculation of Type 2 Virus

All that it is possible to say at present is that the flocculation reaction does take place with type 2 virus and is likely to follow the same pattern as that with the viruses of types 1 and 3. The relatively poor growth of the Lansing strain in HeLa cell cultures led us to abandon it to concentrate on work with Brunhilde and Leon. Recently we have established cultures of the Y-SK strain of type-2 virus in HeLa cells and prepared antigens for rabbit immunisation, but a strain-specific homologous antiserum is not yet available. The Y-SK antigen, however, has been shown to flocculate with a rabbit antiserum against strain MEF1 kindly supplied by Dr. Tyrrell; it shows no sign of flocculation with our Brunhilde and Leon antisera.

Reactions with Human Sera

With the reagents so far available only a few preliminary tests of human sera have been possible, but these have clearly shown that poliomyelitis viruses may be flocculated by the type-specific antibodies which occur as a result of natural infection. Brunhilde antigen was flocculated by both acute and convalescent sera of a proved case of type 1 non-paralytic poliomyelitis in a child of 3 years, whereas neither serum showed any trace of reaction with Leon antigen. Conversely, the convalescent serum of a proved case of type 3 paralytic poliomyelitis in a child of 18 months flocculated the Leon antigen but not the Brunhilde antigen. The acute-stage serum of this patient did not flocculate either antigen. The tests were done with serum dilutions of 1 in 5 and 1 in 10.

Discussion

Discovery of a new phenomenon inevitably leads to speculation. It is therefore important to distinguish clearly between *what must be accepted as fact and what is merely possibility*. The essential facts definitely established by *our experiments may be stated in very simple terms*. An antigen-antibody reaction occurs in a mixture containing poliomyelitis virus and its homologous antiserum which under appropriate conditions and with suitable preparations of the virus antigen leads to macroscopic flocculation; furthermore, the reaction is strictly type-specific. It must be emphasised, however, that, so far, this flocculation phenomenon has been demonstrated only with antigens made from single strains of each virus type, with antisera from immunised rabbits, and with human sera from two cases of poliomyelitis in young children. Even so, it is quite certain that direct poliomyelitis virus flocculation can now be used as a research tool to explore the surface structure of these viruses and to investigate some of their biological *characteristics*.

One of the most urgent needs in current work on poliomyelitis is a simple and rapid in-vitro method of typing virus and of detecting and assaying the serum antibodies concerned in protection against infection. The value of such a method in the fields of serological diagnosis, production, and standardisation of vaccines, and epidemiology would be incalculable. There is obviously a possibility, perhaps even a probability, that the direct virus flocculation reaction may meet this need. If so, its simplicity and rapidity are such that tests could be made almost anywhere, because the only apparatus needed would be agglutination tubes, racks, graduated pipettes, and a water-bath. Results of a titration are as easy to read as those of a routine Widal test. But the possibility *can only* be determined by further work along several different lines. The number of relevant problems calling for investigation is too large to categorise, but those of particular urgency are the question of stability of the virus antigens, the correlation of flocculating antibodies with the neutralising and complement-fixing antibodies of various kinds of sera, the possibility that the reaction may be not only type-specific but also strain-specific, and the possible occurrence in sera of non-specific flocculation inhibitors. One essential for systematic attack on each of these problems is an adequate supply of antigens of all three types of virus from different strains. Though this would present no difficulty, given the equipment for virus culture on a really large scale, a microflocculation method would be advantageous for many kinds of test. Work to this end has already yielded very promising results which, if confirmed, will be published shortly.

Summary

A direct poliomyelitis virus flocculation reaction is described. This is type-specific and occurs in mixtures of concentrated suspensions of virus and homologous rabbit antisera. Flocculation has also been demonstrated with human sera from two cases of poliomyelitis in children.

Possible uses of the reaction and the relative problems requiring investigation are briefly outlined.

The *Encyclopædia Britannica* defines genius as "the highest conceivable form of original ability, something altogether extraordinary and beyond even supreme educational prowess", and in this definition one notes what is certainly a characteristic attitude of the beholder, that of astonishment, which gives rise to the notion of mystery. Of all the characteristics of genius Revesz selects *surprise* as being the most central, to which all others are accessory, and this seems to accord with the frequency with which geniuses receive their inspiration in a sudden flash that startles the recipient himself. In describing a recent discovery in physics Dr Gabor remarked: "This statement has that touch of offending common sense which is the hallmark of every truly important scientific discovery." Freud's discoveries, said Dr Jones, satisfied this criterion in full measure.

Allied to this feature of intuitive inspiration is the characteristic spontaneity with which the productions of genius appear. They can never be brought about by a deliberate effort of will, and nothing can ever force them. An attitude of passive surrender towards the flowing in of the valuable ideas must be significant for the psychology of the productive process.

Of the features characteristic rather of scientific production than of artistic inspiration the most obvious is the indispensable one of absolute honesty: "the first and last task required of genius," wrote Goethe, "is love of truth." Closely akin to this mysterious feeling for what is true seems to go a sense of what is significant. This enables, or compels, a genius to generalise a finding where a lesser mortal would cautiously go on collecting more evidence before venturing on a general statement. Freud, though he would be accounted a man of sober and reflective judgment, afforded several instances of this kind of superlative boldness and sureness.

A further attribute of genius is the power of concentration. Buffon held that *genius is nothing else than a greater aptitude* for patience than that possessed by other men, and Carlyle described it as "first of all a transcendent capacity of taking trouble." Another writer, referring to "the self-surrender so familiar to creative minds," says: "The concentration of such a state may be so extreme that the worker may seem to himself or to others to be in a trance"—as happened when Freud was composing the final chapter of *The Interpretation of Dreams* in 1899 and sometimes seemed oblivious of his surroundings.

"What is the significance of this extraordinary concentration and intensity?" Dr Jones asked. "What powerful impulses are driving their way at such moments? For there is every reason to suppose that men of genius are characterised by possessing exceptionally strong emotions and usually a correspondingly strong capacity for containing them. The tension induced by the preceding efforts to find a solution gradually mounts until it reaches a climax. The great mathematician of genius, Henri Poincaré, in describing how he made his own discoveries, said: 'One is struck by these appearances of sudden illumination, obvious indications of a long course of previous unconscious work. . . . These sudden inspirations are never produced except after some days of voluntary efforts which appeared absolutely fruitless.' Evidently there must be a special coincidence between the unconscious impulses and some essential feature of the objective problem. In the preliminary cogitation various shiftings and similar mechanisms are going on in the unconscious the purpose of which is to achieve a sufficient degree of harmony with the censoring functions of the super-ego by means of which the accompanying guilt is kept in abeyance. At the successful moment there must have been achieved a quite remarkable degree of integration between the ego, the super-ego, and the id. It is no doubt this successful degree of synthesis, the overcoming of all barriers, that accounts for the sense of elation at the final moment of triumph."

The lecturer believed that an essential prerequisite of the productivity of genius must lie in a particular scepticism. He must have refused to acquiesce in certain previously accepted conclusions. This argues a kind of imperviousness to the opinions of others, notably of authorities. Furthermore, he often has the capacity of seeing the existence of a problem where others have passed it by; he has refused to take something for granted as being either without meaning or too insignificant to bother about. This aloofness sets him free to speculate and investigate. But Freud himself once pointed out to Dr Jones that such freedom is always obtained under the condition that another aspect of mental functioning is inhibited. "It may well be that the compensatory inhibition of which Freud spoke is the explanation of a feature often remarked in men of genius—namely, a certain naïveté, marked simplicity, and ignorance of the ways of the world.

"The scepticism and imperviousness to opinion of which I have spoken were prominent features of Freud's personality and they extended over a wide field. Not long after getting to know him, however, I was struck by an exactly opposite feature, one which, it is true, operated in a far more limited field. I refer here to a curious credulity, a willingness to believe what he was told whether it was really likely or not. To it I would ascribe his well recognised difficulty in forming an accurate estimate of personal character, a deficiency of which he himself complained. . . . Pascal pointed out that greatness is never at one extreme but consists of the union between two extremes, an idea which Sainte Beuve later labelled the theory of the *entre-deux*. My own suggestion is a particular application of this."

Wondering whether his observation concerning Freud's personality could have any more general validity as a condition for the productivity of scientific men of genius, Dr Jones studied the characteristics of others among them. The reputation of Copernicus, he said, rests on his scepticism—on his doubting whether the sun revolves round the earth. But in questioning the views of Ptolemy, Copernicus was trying to justify Aristotle's dictum that all the heavenly orbs and orbits must have the form of a perfect circle; for in Aristotle's infallibility he had a credulous belief. In Sir Isaac Newton's personality both scepticism and credulity were prominent. His published work is marked by a rigid objectivity, and it was he who proudly proclaimed the famous sentence, *Hypotheses non fingo*; yet in earlier days he had spent much time in search for the philosopher's elixir and the means of transmuting metals into gold, and throughout his life theology was much more important to him than science—and, moreover, theology of a peculiarly arid and bigoted order. Faraday, the supreme physicist of the 19th century, had also his vein of credulousness: throughout his life he was an adherent of the obscure sect of Sandemanians, and for three years regularly preached sermons before them. In Darwin scepticism was tempered by a credulous attitude towards other authorities: even after his great discovery of the operation of evolution through natural selection he still believed in Lamarck's doctrine of evolution through the inheritance of acquired characters, a doctrine his own work had rendered superfluous. His friend and contemporary Huxley offers a very interesting contrast: he had a wider knowledge than Darwin, more originality, greater intellectual daring and any amount of scepticism; but there is no record in his life of any evidence of credulousness to match it and (according to Dr Jones's view) enable him to make really great discoveries. "Perhaps it is worth mentioning in the present connection the remarkable epidemic of belief in the cruder aspects of spiritism that infected several of the leading English physicists early this century: Sir William Barrett, Sir William Crookes, Sir Oliver Lodge, and Sir George Stokes. The number of times the mediums in whom they trusted were exposed as frauds made no difference to the tenacity of their beliefs."

After speaking, in psycho-analytical terms, of the possible correlation between credulousness and the characteristically receptive nature of genius, Dr Jones ended his lecture[1] by saying that it will probably be generations before all the implications of Freud's ideas are fully worked out and the stimuli he provided for us fully acted on. "Revolutions in thought such as he brought about do not happen very often in history, and it may well be long before another similar one takes place."

REMUNERATION OF SENIOR HOSPITAL MEDICAL OFFICERS

UNDER an Industrial Court award, the remuneration of the 2631 S.H.M.O.s in the National Health Service (including 1190 employed part time) is increased by £75 a year. Hitherto the scale has been £1500–£1950.

---

[1] This will form one of a collection of essays to be published by Basic Books Inc., New York, and distributed in this country by Tavistock Publications.

TABLE II—BLOOD FLOW
(ml per 100 c cm of tissue a minute)

—	Normal heat exchange		Reflex vasodilatation		Reflex vasoconstriction	
	Operated side	Non operated side	Operated side	Non operated side	Operated side	Non operated side
Sympathectomised patients	9·0	3·1	12·4	19·0	11·8	13·0
Non sympathectomised patients		2·8		14·1		9·4
Healthy people		3·1		14·8		9·3

The technical quality of the operations was assessed by an independent examination of the operation notes without prior knowledge of the blood flow estimations The criteria used in this assessment were (1) the description of the operation in the notes, the difficulties of access, the amount of hæmorrhage, &c , (2) the surgeon's estimate of the amount of sympathetic tissue removed , and (3) histological evidence of the removal of sympathetic nervous tissue Although such an assessment is bound to be imprecise it nevertheless gives a reasonable idea of the technical efficiency of the operation, each being classified as " good," " bad," or " doubtful " Table III shows the results of this analysis together with the time between the operation and the blood-flow estimation, the presence or absence of the vasomotor reflexes, and the degree and duration of improvement in the patient's vascular symptoms after the operation A " t " test of the difference between the means of the blood flow of " good " and " bad " operations shows that this difference is statistically significant ($p<0·01$)

The comparison of the blood flow under conditions of normal heat exchange and the assessment of the quality of the operations are shown graphically in fig 2

Illustrative Case-reports

Patient 10—Female Born 1899 Attack of anterior poliomyelitis during infancy affecting mainly the right lower limb Coldness, cyanosis, and chilblains of the right leg since the age of 21

March, 1952 extensive right lumbar sympathectomy during which no technical difficulties were encountered In surgeon's opinion D12–L3 sympathetic ganglia were removed A total length of seven inches of sympathetic chain was removed, including a double chain between the L2 and L3 ganglia Histological examination confirmed the removal of sympathetic nervous tissue

Result—The patient's symptoms were considerably improved after sympathectomy, and this improvement has been maintained Blood flow of feet examined thirty five months after operation resting blood flow on operated side was 21·2 ml per 100 c cm of tissue per minute

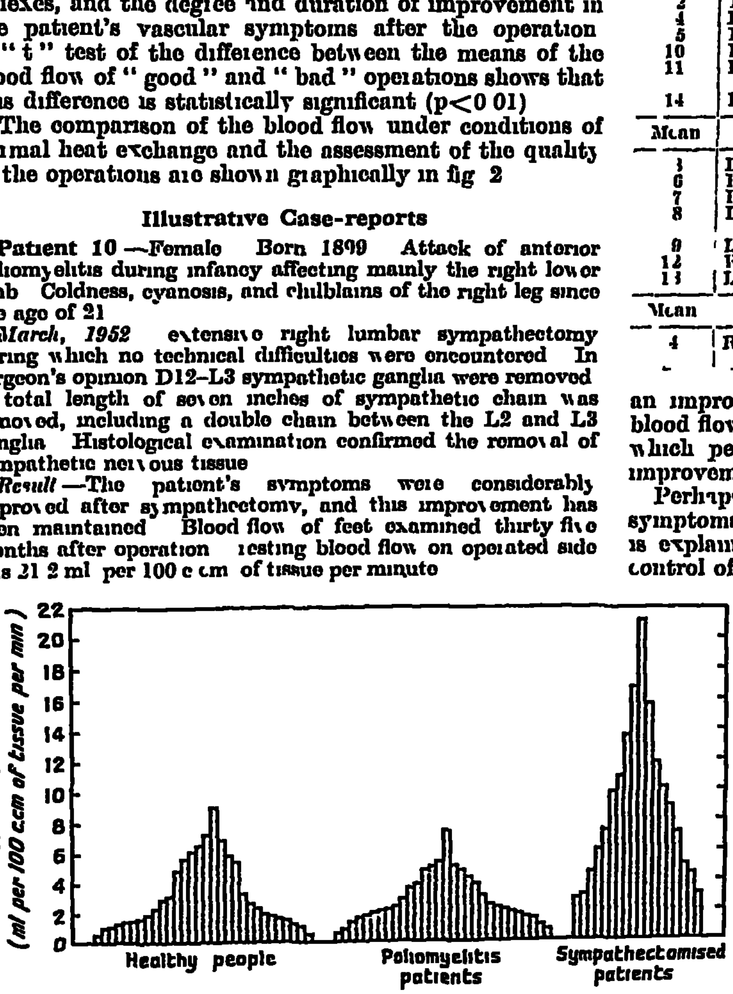

Fig 1—Blood flows of all persons studied

Patient 9—Female Born 1937 Attack of anterior poliomyelitis in 1942 affecting mainly the left lower limb Coldness, cyanosis, chilblains, and ulceration of the left leg since 1945

October, 1953 left lumbar sympathectomy during which there was moderate venous bleeding and the ganglia were difficult to identify In surgeon's opinion only L2 ganglion had been removed Histological examination confirmed the presence of sympathetic nervous tissue

Result—After the operation there was moderate improvement in the patient's vascular symptoms which lasted for only two months Blood flow of feet examined sixteen months after the operation resting blood flow on operated side was 7·2 ml per 100 c cm of tissue a minute

Discussion

An interesting feature of this investigation is that only one of the eighteen operations to remove sympathetic ganglia failed to produce some improvement, however short lived, in the patient's symptoms Of the 8 patients subjected to operations described as " bad " 2 showed an improvement which was still maintained when the blood flow was investigated , 5 showed an improvement which persisted for some months , and 1 showed no improvement

TABLE III—ANALYSIS OF RESULTS

Patient no	Operated side	Assessment of operation	Normal heat exchange blood flow (ml per 100 c cm per min)	Time since operation (mos)	Vasomotor reflexes	Symptomatic improvement	
						Quality	Duration (mo)
1	Both	Good	9·9	20	–	Good	20
		Good	10·2	20	–	Good	20
2	Right	Good	15·7	21	–	Good	21
4	Left	Good	10·9	17	–	Good	17
5	Right	Good	16·8	43	–	Good	43
10	Right	Good	21·2	35	–	Good	35
11	Both	Good	13·6	180	–	Good	180
		Good	11·8	22	–	Good	22
14	Right	Good	9·0	11	–	Good	11
Mean			13·2	41			41
3	Left	Bad	6·0	43	+	Good	30
6	Right	Bad	4·5	25	–	Good	25
7	Right	Bad	4·4	21	+	None	0
8	Both	Bad	2·8	67	+	Slight	[illegible]
		Bad	3·0	60	+	Slight	3
9	Left	Bad	7·2	16	–	Mod te	2
12	Right	Bad	5·0	26	+	Good	26
13	Left	Bad	3·0	25	–	Good	[illegible]
Mean			4·5	36			[illegible]
4	Right	Doubtful	7·3	17	–	Good	17

Perhaps the temporary amelioration of the vascular symptoms that follows a " bad " lumbar sympathectomy is explained by the temporary interruption of nervous control of the blood vessels and the subsequent recovery of local arterial tone, as described by other workers The temporary vasodilatation occurs, as can be shown by plethysmography even in cases in which there is no histological evidence of any sympathetic nervous tissue having been removed—e g , patient 8 Moreover the fact that, in this investigation, every patient whose vasodilatation was only temporary had a " bad " operation is unlikely to be explained merely by coincidence In our opinion it appears more likely that any attempt to remove sympathetic ganglia produces sufficient trauma of sympathetic nervous tissue to produce a temporary paresis of the sympathetic nerve supply to the blood vessels, even though no nervous tissue may have been resected The eventual recovery of arterial tone could then be

ON DIAGNOSING CANCER HISTOLOGICALLY*

W WALLACE PARK
M.B Edin
LECTURER IN PATHOLOGY, UNIVERSITY OF ST ANDREWS

WHEN a pathologist makes a histological diagnosis of cancer he is doing two things He is giving a prognosis for the patient concerned, and he is also influencing the treatment of future patients, for his dictum inevitably forms part of the body of knowledge from which the ' facts " of incidence and curability of cancer will subsequently be deduced For those who deal with the problem of cancer—surgeons radiotherapists, statisticians, and others—it is clearly important that they should know just how closely histological diagnosis can approach absolute accuracy The pathologist himself is none the worse for studying the factors that influence his judgment

The pathologist giving a histological diagnosis of cancer is too often regarded as a dispenser of absolute truth The wide use of and faith in, the term " histologically proved " is evidence of this attitude In fact, it is not possible to make an absolute diagnosis of cancer by microscopy in that the causal agent, whatever it be, cannot at present be seen in the lesion The analogy with the histological diagnosis of tuberculosis or leprosy, where the causal agent can be seen, scarcely merits pressing here except as a contrast to the actual basis on which a histological diagnosis of cancer is founded

Basis of Histological Diagnosis

A histological diagnosis of cancer is, in practice, founded on three sources of evidence the gross specimen, the sections made from it, and the clinical data

Macroscopic Evidence

The appearance of the gross specimen is never the final arbiter in a borderline case It may, of course, raise suspicion, and, as has been said " suspicion is the beginning of diagnosis ' To the pathologist, and surgeon, of experience the naked-eye appearances usually indicate the zones that demand microscopic examination

Microscopic Evidence

The important evidence lies in the sections, stained in whatever ways may be appropriate As already mentioned, a causal agent cannot be seen All we can use as evidence are alterations from the normal in cell structure and in tissue architecture Diagnosis is then based upon an almost wholly empirical association—namely, the experience of pathologists in general has shown that such histological appearances are, in almost all cases, associated with increasing progression of the disease and shortening of the life of the untreated and even of many treated, patients In practice, of course, in straightforward cases the pathologist gives his outright diagnosis with confidence He does not set out his argument along these lines, but that is his reasoning, and that is what he implies

" Clinical Cancer " and " Histological Cancer "

We recognise a case as straightforward when the alterations in tissue pattern are obvious, and the correlation between these morphological alterations and subsequent death of a particular type is very high Diagnostic difficulties become progressively greater, the lower this correlation is, and it is because the level of the correlation is so low at what we call the early stages of cancer that our diagnostic criteria at that stage are so poorly defined. The best we can do is, as it were, to extrapolate the lethal tissue patterns backwards and try to visualise them at an earlier stage We do, however, use clinical correlations as long as we can When we give a diagnosis of early cancer we do so because we feel that this kind of histological appearance has in the past on some occasion been correlated with progression of the disease Diagnosis of cancer from the florid or straightforward case down to cases at this level is diagnosis of *clinical cancer*

There is, however, another school of thought prepared to extrapolate tissue patterns even further backwards—in fact beyond the point where a significantly positive correlation with the subsequent manifestation of clinical cancer virtually disappears This school argues that a histological pattern may be so atypical that only cancerous growth can explain it This is the type of cancer we are told is present in the prostate of some 30–40% of men over the age of 50 Yet nothing like 30–40% of men over the age of 50 die from prostatic cancer, so we can assume that cancer is being defined here in terms quite different from those used in defining clinical cancer This is, in fact *histological cancer* There is, possibly, no harm in using the term ' cancer of the prostate ' to describe these appearances as long as this kind of cancer is not equated with clinical cancer, and as long as it is understood that when a man has had such an organ removed he has been cured, not necessarily of a lethal disease, but of a certain histological appearance within his prostate Diagnoses made in this way, and such terms as ' histologically malignant but clinically benign," require to be regarded with caution if cancer pathology is to be treated as properly it should as a science

Histological " Criteria of Malignancy '

When we make the diagnosis of ' cancer " at a low level of clinical correlation it is extremely difficult to know how close to the truth we are approaching for the obvious reason that it is almost impossible to distinguish between *early* diagnosis and *wrong* diagnosis If a lesion, diagnosed as cancer, but wrongly diagnosed in that it is not a cancer, is completely removed the records will wrongly show that a cancer has been " cured " If on the other hand, the histologist has a high, perhaps unjustifiably high diagnostic threshold for cancer a truly malignant lesion may be diagnosed as " not cancer ' and the surgeon be cheated out of a genuine cure The pathologist's difficulty is that he must try to visualise the earliest stages of those abnormal tissue patterns which, when at their maximum in the " obvious " case, form unmistakable evidence of atypical and excessive growth of cells These patterns are manifest as (*a*) cell polymorphism accompanied by a varying degree of mitotic activity, and (*b*) the property which we call " invasiveness "

Neither of these properties can be depended upon absolutely *Cell polymorphism* is abundantly seen, for example, in granulation tissue, and indeed the distinction between active granulation tissue and sarcoma can at times be perplexingly difficult, especially as mitotic figures may be seen in both Polymorphism of cells is also prominent in many cases of Hashimoto's disease, so much so as to lead to an occasional wrong diagnosis of cancer difficulty may also be increased here by the presence of mitotic figures in the hyperplastic tissue Polymorphic growth is almost characteristic of proliferative trophoblast, such as is seen in some hydatidiform moles or even in simple placental polyps These are specific instances, but the same difficulty arises more generally because of the polymorphism and mitotic activity so often seen in ulceration of epithelial surfaces It is clear, therefore, that there are occasions in plenty when cell polymorphism and mitotic activity cannot be accepted as diagnostic criteria of malignancy

Invasiveness—This property of malignant growth becomes manifest sooner or later, but it is particularly

MIXED STAPHYLOCOCCAL INFECTIONS

THE DEVELOPMENT OF PENICILLIN-RESISTANT STRAINS

R. W. FAIRBROTHER
T.D., M.D., D.Sc. Manc., F.R.C.P.
DIRECTOR OF CLINICAL PATHOLOGY, MANCHESTER ROYAL INFIRMARY; HON. READER IN CLINICAL PATHOLOGY IN THE UNIVERSITY OF MANCHESTER

STAPHYLOCOCCAL infections constitute a major clinical problem, particularly in hospitals. They are relatively numerous (ranging from a mild superficial pustule to a fulminating pneumonia or enterocolitis) and an increasing proportion of them are caused by strains resistant to antibiotics, especially penicillin.

Barber and Rozwadowska-Dowzenko (1948) drew attention to the rising incidence of penicillin-resistant strains of *Staphylococcus aureus* by reporting that, in the same London hospital, the number had risen from 14% in 1946 to 59% in 1948. Many similar reports have since been published, and at present in the U.S.A. it is considered that 75–80% of staphylococcal infections in hospitals are caused by penicillin-resistant strains (Long 1955, Spink 1955). This high incidence is, so far, confined to inpatients, but there is some evidence that penicillin-resistant infections are also appearing with greater frequency among outpatients (Rees et al. 1955).

The origin of penicillin-resistant strains has not been satisfactorily explained. It has, however, been firmly established (1) that the resistance of naturally occurring strains of *Staph. aureus* to penicillin is due to the production of the enzyme penicillinase, and (2) that this enzyme is not produced by strains rendered resistant to penicillin in the laboratory. Thus there are two quite distinct mechanisms whereby resistance to penicillin is developed. I deal here with only the naturally occurring penicillin-resistant strains—i.e., the producers of penicillinase. It has been found that these strains are unstable. Barber (1949) obtained penicillin-sensitive variants from old cultures of penicillin-resistant strains of *Staph. aureus*, and Fairbrother et al. (1954) found that such variants readily appeared during the incubation of penicillin-resistant strains at 44°C. Penicillinase-producing variants have not, however, been obtained from cultures of penicillin-sensitive strains of *Staph. aureus*.

Investigations into the appearance of variants in infections have been few. Barber and Whitehead (1949) reported the isolation of both penicillin-sensitive and penicillin-resistant strains of *Staph. aureus* from the same patient, but from somewhat inconclusive phage-typing and serological tests they concluded that the strains were of different types and therefore had separate origins. Fairbrother et al. (1954) isolated penicillin-sensitive and penicillin-resistant colonies of *Staph. aureus* from the same cultures of infective material and found that, on six occasions, these had the same phage pattern, probably originating from the same parent strain.

The present investigation is a continuation of the study of the development of variant strains of *Staph. aureus* under natural and experimental conditions and provides a further explanation of the probable origin of the variant strains.

Methods

All material from infections was routinely seeded on to appropriate media, including blood-agar plates, and, after overnight incubation, plate cultures exhibiting colonies of *Staph. aureus* were selected for study. After careful examination with a hand lens representative colonies were selected for coagulase and sensitivity tests; if any variation in the colonial appearance was detected, 10–20 discrete colonies were investigated. The coagulase tests were done by the tube technique. The antibiotic sensitivity tests were initially made by the disc and strip techniques with pure cultures; but, where indicated, the serial dilution method was also used (Fairbrother and Martyn 1951). The penicillinase tests were done by the cylinder technique. The strains were phage-typed at the Public Health Laboratory, Manchester.

Throughout this work penicillin-sensitive strains of *Staph. aureus* proved to be coagulase-positive, were inhibited by $^{1}/_{16}$–$^{1}/_{32}$ unit per ml. of penicillin, gave a clear zone round the penicillin discs, and did not produce penicillinase. Penicillin-resistant strains of *Staph. aureus* were coagulase-positive, produced penicillinase, did not give a clear zone round the penicillin discs, and were not inhibited by at least 10 units per ml. of penicillin.

Results

The results fall conveniently into two main groups: those obtained in vivo from the examination of pus or other material from infections, and those produced in vitro with strains of *Staph. aureus* recently isolated from human infections.

ISOLATION FROM INFECTIVE PROCESSES

Incidence of Penicillin-resistant Strains

There are many reports, from different parts of the world, of the increase in penicillin-resistant strains isolated from hospital communities. Since the introduction of the disc technique in 1950 sensitivity tests have been made in this hospital as a routine, and analysis of consecutive samples of strains isolated at different times from the total hospital population (table I) shows an increasing incidence of penicillin resistance.

A more detailed analysis of the 1955 figures shows that 142 of the 550 strains were isolated from outpatients and 52 (37%) of these were penicillin-resistant, whereas 260 (64%) of the 408 strains isolated from inpatients were resistant. There was thus a much higher incidence of resistant strains among the inpatients, although the outpatient figures tended to be rather higher than those previously reported (Forbes 1949, Rees et al. 1955). The outpatient strains were collected largely from chronic and subacute infections, many of which had already been treated unsuccessfully with penicillin. Moreover among the strains from inpatients many were isolated from severe fulminating infections admitted as urgency cases; these are really representative of strains from the general population rather than the hospital.

TABLE I—INCIDENCE OF PENICILLIN-RESISTANT STRAINS OF *Staph. aureus*

Period	No. in sample	No. penicillin-resistant
1950–51	600	259 (43%)
1953–54	300	172 (57%)
1955	550	312 (57%)

During this period 60 strains of *Staph. aureus* were isolated from material sent by general practitioners from a health centre, and 20 (33%) were penicillin-resistant. There is thus disturbing evidence that the incidence of penicillin-resistant strains among the general community is also increasing.

Appearance of Variants in Infections

The possibility of staphylococcal variants developing in vivo has received little attention. Barber and Whitehead (1949) isolated penicillin-sensitive and penicillin-resistant strains of *Staph. aureus* from 11 patients, but in 8 of these patients one or both of the pairs of organisms were untypable; it was concluded that the organisms were probably of different origins. Fairbrother et al. (1954) found that 6 of 13 mixed cultures gave the same phage pattern and probably originated from the same parent strain.

Further investigations were made. Colonies were studied in many cultures; in the great majority the colonies appeared identical on examination with the hand lens, and sensitivity tests of a representative sample definition. A similar state of affairs—many other examples could be given—is afforded by the section of endometrial curettings showing hyperplastic trophoblast, and the suspicion is chorionepithelioma. It is probably true to say that given equally suspicious histological appearances a preceding history of hydatidiform mole is more likely to lead to a diagnosis of malignancy than a history of abortion or normal pregnancy. Chorionepithelioma certainly does follow hydatidiform mole with disproportionate frequency, but this fact clearly cannot alter the histological characters in a section. If the histologist, knowing the clinical data, gives the graver prognosis he is doing so, once again, by virtue of his clinical not his histological, knowledge.

The piece of clinical information which, known in advance, exceeds all others in warping one's histological judgment is knowledge of the patient's age. Foreknowledge of the sex is unlikely to cause bias in the diagnosis of malignancy—though it may delay the pathologist's own realisation of the close similarity shown by carcinomas of prostate and of ovary—but foreknowledge of the age of the patient can certainly do so. Few will deny that a borderline lesion—for example, a squamous cell overgrowth of lip—is much more likely to be diagnosed as carcinoma at age 50 than at age 15. The reasoning behind this practice is that since cancer of the lip (or other organ) is much commoner at age 50 than at age 15, a histologically borderline lesion at age 50 probably is cancerous but at age 15 probably is not cancerous. This reasoning is false, and based on a quite wrong use of probabilities. Cancer of the lip certainly is rare at age 15, but so are borderline appearances. The critical question is how often borderline appearances indicate malignancy irrespective of age. Largely because of lack of definition of what we call the borderline picture, there is as yet no exact answer to this question. The proper position at present is that if histological appearances are regarded as indicative of malignancy at age 50, then unless we propose to adopt different criteria of malignancy for every age-group (and how many groups should there be?), the same histological appearances are equally indicative of malignancy at age 15 or at any other age. If the pathologist, already knowing the age of the patient, is confronted by a borderline lesion of this kind, we can be fairly sure that he is unlikely to make a diagnosis of malignancy in the patient of 15. The pathologist would like to believe that he is immune to such a biasing influence, but this in effect is what happens to a greater or lesser extent in every report where the age and other data are studied in advance.

The self-discipline involved in "blind" examining has the additional valuable humbling effect of making the histologist realise how helpless he can be without information about site, age, and other clinical details. Current practice is such that, on proffering a section to a colleague, we are hesitant even to ask whether he would like to have the clinical data before or after his examination. We shrink from the thought of being charged with sharp practice, and are fearful lest we make our colleague appear foolish in diagnosing, say, carcinoma of the prostate in a woman, or glioblastoma multiforme in a pelvic mass; though, such are the limitations of histological technique, and so non-specific many of our criteria, that such diagnoses, in so far as they are purely histological interpretations, might not be so foolish at all.

It is only by examining sections and making up our minds on the question of malignancy or non-malignancy on histological evidence alone that we can hope to appreciate exactly what the limitations of histological interpretation are; and gradually, by this appreciation, to define more sharply the criteria by which we diagnose malignancy. The value of this procedure depends ultimately, of course, on knowledge of the fate of the patients whose sections we have diagnosed, and for this we are mainly dependent on the good offices of our surgical and radiotherapeutic colleagues. Our current criteria of malignancy would probably be less hazy at the edges and our standards of diagnosis of malignancy in marginal cases much higher, if follow-up departments had been initiated by departments of pathology forty or fifty years ago.

It is true that the habit of always examining sections "blind" at the outset adds a few minutes to the time required for reporting. To that extent it is a time consuming practice. That it is a time-wasting practice is, I consider, emphatically not the case.

Everyday Diagnostic Problems

These observations have application to everyday diagnostic problems, particularly in view of the double purpose we achieve in giving a diagnosis of cancer—prognosis for the individual patient, and provision of data for later studies on cancer in general. In order to see briefly how these observations do apply, we may divide neoplasms into three main groups.

CASES WITH PREDICTABLE BEHAVIOUR

The largest group comprises the straightforward cases—cases where as already mentioned, evidence of atypical cell behaviour is abundant, and the correlation of this with metastasis and a lethal outcome is high. Such cases may be "straightforward," but even here we may recall that diagnosis is not absolute. Our diagnosis which is prognosis is based, and for pragmatic reasons must be based, on the assumption that, in the absence of treatment, the lesion represented by the abnormal tissue pattern will progress and shorten life. In making this assumption we are not taking into account the fact that cancers vary greatly in their behaviour, not only in different organs but within the same organ. The recurrence of a cancer, locally or as a metastasis, ten years or more after its initial removal is well known and not infrequent. There is no method meanwhile whereby we can distinguish the original cancer of this type from any other in the same histogenetic family. A cancer which kills in six months may look quite similar to one which does not recur for ten years or more. Highly cellular cancers do, it is true, tend to grow more rapidly than less cellular ones, but all pathologists and surgeons are familiar with instances where a relatively poorly cellular densely scirrhous cancer, exhibiting, one would think, defensive fibrosis at its maximum kills within a matter of months. Handicapped by this inability to distinguish cancers of different growth-rates, the pathologist can only give the same diagnosis, or prognosis, to each. The ways in which this variability of growth-rate and behaviour may influence cure-rates are obvious.

CASES WITH UNPREDICTABLE BEHAVIOUR

This group is formed of neoplasms whose histological characters give no dependable clues to future behaviour. Past experience has shown that, in this group, tissue with a benign future may look just the same as tissue with a malignant future. The pathologist can thus supply little more than the rather unhelpful information that such neoplasms sometimes metastasise; he cannot predict the probability of this with useful accuracy. This is not a large group but it is, by its very nature, an interesting group histologically.

This peculiar difficulty—the lack of correlation between tissue patterns and likelihood of metastasis—arises in some forms of thyroid neoplasia. The extreme example would be the so-called benign metastasising goitre—a lesion which, to judge from reported cases, must be exceedingly rare nowadays. Some thyroid growths which are recognisably neoplastic but not obviously carcinoma do metastasise and kill; other

TABLE V—DEVELOPMENT OF PENICILLINASE PRODUCING VARIANTS FROM PENICILLIN SENSITIVE STRAINS OF *Staph aureus*

Source of original culture	No tested	Incidence of penicillinase producing variants
Infected material	8	0
Variant colonies from resistant strains	8	2

A further series was then tested, and in this the organism used for the test was a penicillin sensitive variant of an originally penicillin-resistant strain (table IV) The original inoculum was a discrete colony from a culture of the penicillin sensitive variant At all stages of isolation this organism proved to be sensitive to $^1/_{16}$–$^1/_{32}$ unit per ml of penicillin and did not produce penicillinase From 2 of 8 strains tested penicillinase producing variants were isolated (table V), one was isolated after 8 subcultures, and the other after 15 subcultures in broth at 33°C In one case the penicillin-sensitive variant could not establish itself in the culture, but in the other it became predominant At all stages the identity of the organism was checked by phage typing

Discussion

The high incidence, in this hospital, of staphylococcal infections caused by penicillin-resistant strains agrees with the general pattern in this and other countries, and evidence was also obtained of an increasing incidence of penicillin-resistant strains among the general population The relatively high rate (37%) in outpatient infections was not altogether surprising, because many of these were chronic or subacute lesions which had not responded to outside treatment, usually with penicillin It is not difficult to explain the prevalence of penicillin-resistant strains in hospitals where cross-infection is easy, and the personnel are often carriers, but the ultimate origin of these strains is uncertain

The main explanations offered for the appearance of naturally occurring penicillin-resistant strains of *Staph aureus* are (1) the acquisition of adaptive enzymes through some metabolic adjustment, (2) the spontaneous appearance of resistant mutants, (3) the survival of rare resistant mutants during penicillin therapy, and (4) a combination of these factors

It is generally accepted that the naturally occurring penicillin-resistant strains differ from penicillin sensitive strains mainly, if not solely, by their capacity to produce penicillinase Moreover it has been established that penicillin sensitive strains of *Staph aureus*, rendered resistant to penicillin by serial transfer in increasing concentrations of penicillin, do not form penicillinase, and that this type of acquired resistance tends to be temporary Little information is available about the possible appearance of mutants or variants in infections, Barber and Whitehead (1949) held that penicillin sensitive and penicillin resistant strains isolated from the same patient tended to belong to different phage types and thus had separate origins

It is generally assumed that the penicillin resistant organisms are the variant or mutant strains (Barber and Burston 1955) This, however, may not be so Another possibility is that the *Staph aureus*, in its original form, was resistant to penicillin, and that the penicillin sensitive strains are the variants or mutants *Staph aureus* is tough and hardy, differing considerably from most other pathogenic organisms of the upper respiratory tract, it is the only member to produce penicillinase or readily to develop resistance to penicillin Although the main reservoir of this organism is now the human nares, this may not always have been the case Probably *Staph aureus* existed formerly under relatively wild conditions in which the capacity to produce penicillinase would be a distinct asset for the survival of the species Penicillinase has little or no value in the cell economy it appears to be mainly concerned with the survival of the organism When the *Staph aureus* became established in the human nares, penicillinase was no longer needed as a defence mechanism, and the capacity to produce this enzyme gradually declined, as an evolutionary process

When penicillin was first introduced as a therapeutic agent, a few penicillin resistant strains were reported by different observers, although previous contact with penicillin was unlikely These strains represented the survivors of the original wild *Staph aureus*, they possessed some essential factors of the enzyme system which is probably controlled by some primitive form of genetic system and is hereditary Subsequent contact with penicillin stimulated the production of penicillinase and eliminated many penicillin-sensitive strains, hence the high incidence of penicillin resistant strains in hospital

Support for this hypothesis is obtained from the results of the present investigation, which has shown that penicillin-resistant strains of *Staph aureus* readily produced penicillin sensitive variants in vitro, whereas penicillin sensitive strains appeared to produce penicillinase-forming variants rarely and only then in special circumstances in which possibly some of the enzyme system was still present in the original culture This is not altogether unexpected, because it is easier to lose an enzyme system than to gain one

It is therefore probable that, when both penicillin sensitive and penicillin-resistant strains of *Staph aureus*, with an identical phage pattern, are isolated from the same lesion, the original infecting organisms were either penicillinase-producing strains readily forming penicillin sensitive variants during the course of the infection, or penicillin sensitive staphylococci still possessing essential traces of the enzyme factor

An increase in the number of penicillin resistant infections throughout the general community seems inevitable, particularly if the practice of using penicillin indiscriminately for all forms of trivial infection continues A serious development is the great increase of severe infections caused by penicillin resistant strains of *Staph aureus*, for which the use of penicillin is not only valueless but also may be dangerous because it delays the introduction of an effective antibiotic A stricter control of penicillin therapy is urgently required

Summary

Of 550 strains of *Staph aureus* recently isolated from infections 312 (57%) were penicillin resistant Previous figures for the same hospital were 42% in 1950–51 and 57% in 1953–54 The incidence of penicillin resistant strains among outpatients was 37%

Penicillin sensitive and penicillin resistant *Staph aureus* with the same phage pattern were isolated from the same lesion on 11 different occasions, this suggests a common origin for these organisms

Penicillin sensitive variants were readily obtained from penicillinase producing strains of *Staph aureus* by growth at 44°C

Attempts to obtain penicillinase producing strains from naturally occurring penicillin sensitive strains of *Staph aureus* were unsuccessful Such variants were, however, produced by 2 of 8 apparently penicillin sensitive strains obtained by growing penicillinase producing organisms at 44°C

It is suggested that *Staph aureus* formerly led a wild existence in which it produced penicillinase, and that this function was later largely, but not entirely, lost by prolonged adaptation to the human nares

It is a pleasure to thank Dr M T Parker for the phage typing results and my colleagues in the department for technical assistance

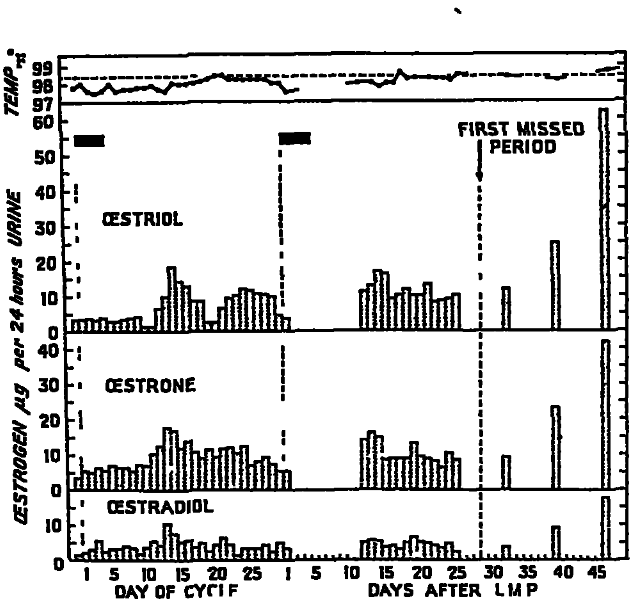

Fig 1

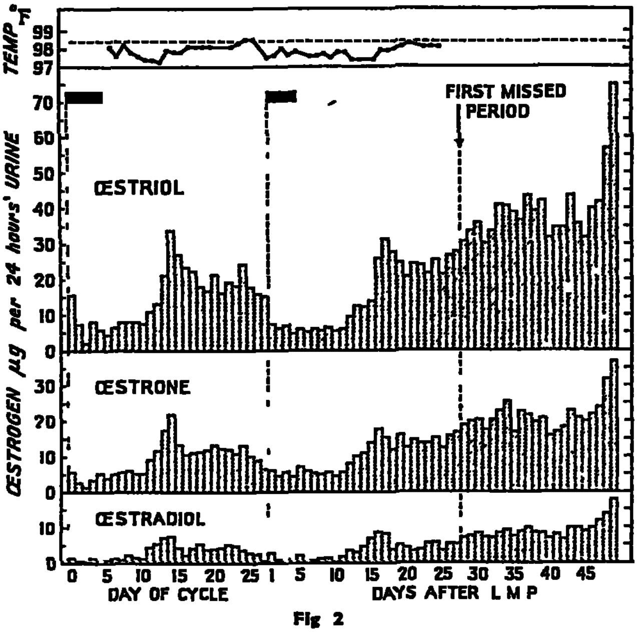

Fig 2

▪ Menstrual period

Fig 1 (subject 7) and fig 2 (subject 8) show the amounts of œstriol, œstrone, and œstradiol excreted per 24 hours and also the variations in basal temperature, during a normal cycle, the cycle in which pregnancy occurred and early pregnancy.

excreted rise from approximately 1 mg per day at 3 months (the smallest amount they could measure accurately) to 20 mg or more per day at 9 months. Later workers (Venning 1948, Clayton and Marrian 1950, Bradshaw and Jessop 1953) confirmed these findings and provided more information about the type and amounts of œstrogens excreted immediately preceding labour and delivery.

Recently a convenient, accurate, and apparently specific chemical method * for separately estimating œstriol, œstrone, and œstradiol-17β in human urine has been developed (Brown 1955a).

Material

Using this method, a study has been made of the daily urinary œstrogen excretion of a woman from before the beginning of a normal pregnancy, up to delivery, and then during the puerperium, lactation, and the recommencement of normal menstruation. The subject of this complete study was a woman (subject 8) who had already contributed urine for œstrogen determination throughout a menstrual cycle (Brown 1955b). A similar but less complete record from another woman previously studied (subject 7) is also included, together with the results obtained from two other women who were studied from the 16th weeks of their pregnancies until the onset of labour.

In all cases, the previous and present pregnancies were uncomplicated. Deliveries were spontaneous except in subject 10 for whom forceps were required. Lactation was established in all cases.

Subject 7, aged 33, para-2 (2 and 6 years ago). Delivery 276 days after last menstrual period (L M P). Baby's birth-weight 8 lb 12 oz (male).

Subject 8, aged 28, para-2 (2 and 3 years ago). Delivery 286 days after L M P. Baby's birth-weight 8 lb $3^1/_4$oz (male). Placental weight 1 lb 11 oz.

Subject 9, aged 27, para 1 (2 years ago). Delivery 289 days after L M P. Baby's birth-weight 8 lb 15 oz (female). Placental weight 1 lb 15 oz.

Subject 10, aged 29, para 0. Delivery 287 days after L M P. Baby's birth-weight 9 lb $3^1/_4$ oz (male). Placental weight 1 lb 12 oz.

Method

Complete 24-hour urine specimens were collected daily from subject 8 and approximately weekly from the others, until 2 weeks before the probable date of delivery, when daily collections were started. Subject 8 also collected all her urine during labour and delivery, 12-hourly for the next 4 days, and then daily until normal menstrual cycles were established.

The amounts of œstriol, œstrone, and œstradiol 17β in each specimen were determined by the method

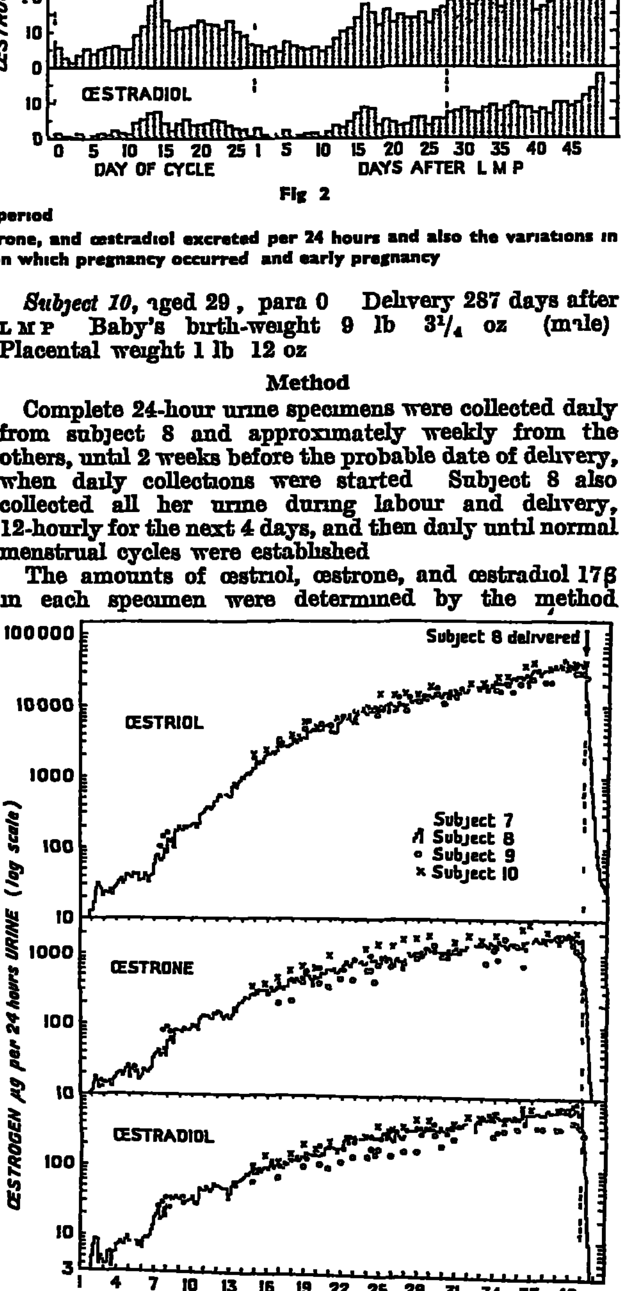

Fig 3—Excretion of œstriol, œstrone and œstradiol during pregnancy in the four subjects and during the puerperium in subject 8.

---

* The two œstrogens 16 epi œstriol and the keto œstrogen recently found in human pregnancy urine (Marrian and Bauld 1955, Watson and Marrian 1955), are not determined by this method nor do they interfere with the results.

in this laboratory, where only 17 6% of 419 penicillin-sensitive strains isolated in 1954–55 from outpatients were not typable at the routine test dilution

Representatives of all four broad phage groups were found, but the number of strains isolated is too small for comparison of their frequency distribution with those found elsewhere

Where two or more strains were isolated from men living in the same locality the strains proved to be of different phage-patterns Although the total number of strains isolated was disappointingly low, the diversity of patterns found indicated that a fair sample of the pathogenic staphylococci present had been examined

Non pathogenic Staphylococci

110 strains of non-pathogenic (coagulase negative) staphylococci were examined for antibiotic sensitivity (table II)

87 of these strains conformed to the definition of *Staph saprophyticus* of Shaw et al (1951), all giving a positive Voges Proskauer reaction, 80 were white and 7 produced a yellow or golden pigment 6 (7%) of these strains were more resistant to penicillin than the control Oxford strain and produced penicillinase Using small inocula, they grew in concentrations of penicillin ranging from 0 075 to 0 6 unit per ml 2 of these strains were resistant also to chloramphenicol, growing in 125 µg per ml 1 strain grew in 2 mg per ml of streptomycin, in 250 µg per ml of chlortetracycline, and in 60 µg per ml of chloramphenicol In addition, 1 penicillin sensitive strain grew in 125 µg per ml of chlortetracycline

TABLE II—PENICILLIN SENSITIVITY OF COAGULASE NEGATIVE STAPHYLOCOCCI

Species	Pigment production	No of strains	Penicillin resistant	Penicillinase producers
Staph saprophyticus	White Yellow	80 7	6	6
Staph lactis	White Yellow	6 17	1 12	1 11
Total		110	19 (*17 3%*)	18

23 strains were classified as *Staph lactis* (Shaw et al 1951) since they fermented glucose but were acetoin negative 17 of these strains produced varying degrees of pigment, ranging from pale yellow to golden Their colonies were more opaque than those of *Staph aureus*, and confluent growth on agar displayed a metallic or iridescent sheen 12 such strains were penicillin resistant and 11 produced penicillinase None was resistant to any of the other antibiotics

Discussion

The low prevalence (19%) of nasal carriers of pathogenic staphylococci among the Wabaga, compared with that of 30–50% found in civilised communities, may be commented on It is tempting to correlate this finding with the small amount of clothing, ordinarily only a few leaves worn by these people, with the absence of communal bathing places (indeed, they wash but rarely), and with their relatively solitary manner of living in small groups These habits, together with their paucity of articles of material culture and the absence of indoor communal meeting places, suggest that they may have fewer opportunities to exchange their staphylococci than have urban communities It would be of some interest to compare their carrier rates with those in civilised but isolated agricultural communities

It is as yet undecided where these primitive people originated or for how long they have lived in the region, but it is likely that, until recently, they had been isolated for many centuries It is quite improbable that they could have acquired the variety of types of *Staph aureus* isolated from them by the limited contact that they have had with white people in recent years It is therefore of considerable interest that their strains of *Staph aureus* were similar to those found in civilised man The antiquity of man's association with the staphylococcus has been discussed elsewhere (Rountree 1955)

Finally, the presence of antibiotic resistant strains, although all were non pathogens, indicated that such strains can indeed occur naturally in the absence of antibiotics manufactured by man

Summary

23 of 120 people of the Wabag region of New Guinea were nasal carriers of *Staph aureus*

None of these strains was antibiotic resistant, but some non pathogenic staphylococci found in nasal swabs were resistant to antibiotics

Phage typing of the strains isolated from these primitive people showed that these were similar to those found in civilised man

This work was supported in part by the Australian National Health and Medical Research Council My thanks are due to members of the Nuffield Expedition, and in particular to Mr B Lockett who collected the swabs and to Prof N W G Macintosh Miss Judith Rheuben and Mr K Miller gave valuable laboratory assistance

EFFECT OF VITAMIN-K DOSAGE ON PLASMA-BILIRUBIN LEVELS IN PREMATURE INFANTS

J P BOUND

FIRST ASSISTANT, CHILDREN'S DEPARTMENT

T P TELFER
M B Melb, D Path
REGISTRAR, DEPARTMENT OF CLINICAL PATHOLOGY

UNIVERSITY COLLEGE HOSPITAL, LONDON

THE effects of large and small doses of a water soluble vitamin K analogue ('Synkavit') on plasma bilirubin levels of premature babies on the fifth day of life are compared here

Investigation

In September, 1954, we began routine estimations of the fifth day plasma bilirubin levels in all surviving premature babies It was hoped that, by correlating these levels with the previous histories of the babies and their subsequent fate, criteria might be established for giving an exchange transfusion to prevent the development of kernicterus in premature babies showing no evidence of blood group incompatibility We were particularly interested in the number of infants attaining plasma bilirubin levels over 18 mg per 100 ml, which is perhaps the upper limit of safety as regards liability to develop kernicterus in hæmolytic disease of the newborn due to blood group incompatibility (Mollison and Cutbush 1951) The fifth day was chosen because it appeared that, preventive action would usually be required at that after this, measurable amounts of œstradiol-17β appeared in the urine and the levels of all three œstrogens rapidly increased and decreased in the manner characteristic of ovulation (Brown 1955b) However, the œstrogen levels did not rise again to a definite luteal maximum and menstrual bleeding began 8 days after the "ovulation" peak That ovulation followed by a shortened luteal phase had occurred was confirmed by morning basal temperature and urinary pregnanediol measurements † An ovulation peak followed by a somewhat shortened luteal phase of 10 days was seen during the next menstrual cycle, and during the third menstrual cycle there was a normal luteal maximum and the œstrogen levels throughout were almost identical with those during the menstrual cycle preceding pregnancy

Discussion

The results reported here are similar to those obtained by other workers, but they give a more detailed picture of some of the changes in urinary œstrogen levels during pregnancy, the puerperium, and lactation

Œstrogen Level During Pregnancy

The levels found during the menstrual cycle in which pregnancy occurred were very similar to those found during the preceding cycle up to the middle of the luteal phase, after which time they continued to rise slowly instead of falling as they do before menstruation At about 7 weeks after the last menstrual period, the urinary œstrogen levels began to increase rapidly, being soon outside the range found during a menstrual cycle, and thereafter they followed a smooth exponential curve which flattened somewhat towards the end of pregnancy

The abrupt change in the œstrogen excretion curve at about 7 weeks might well be due to the changeover from the corpus luteum to the placenta as the major producer of œstrogens This is earlier than the time suggested for this changeover by Venning (1948) who thought that it took place during the 2nd to 3rd months However, many workers have noted that the removal of the corpus luteum, even during the first month of pregnancy, does not necessarily cause abortion Koff and Tulsky (1953) concluded from this evidence, and from their own studies on eight women in whom they estimated urinary pregnanediol before and after removing the corpus luteum, that by the 35th day the placenta by itself secretes enough progesterone to maintain pregnancy This should apply equally to the œstrogens, and it would therefore seem that the rapid increase in œstrogen excretion observed at 7 weeks is caused mainly by placental production, and that even before this time the placenta is contributing increasingly to the œstrogen levels

Œstrogen Levels During and After Labour

My findings during late pregnancy and at the onset of labour are very similar to those reported by other workers, and support the conclusions of Bradshaw and Jessop (1953) that there is no correlation between œstrogen excretion and the onset of labour The considerable day-to-day variations in the excretion of œstrogens in the same woman and the variations in secretion between different women noted by Bradshaw and Jessop were also observed in my series These differences are masked in the logarithmic scale used in fig 3 but are shown more clearly in the table

The rapid decrease in the urinary œstrogen levels following delivery was consistent with sudden removal of the placental source and a continuous metabolism and renal excretion of the remaining œstrogens Œstriol was eliminated more slowly than œstrone and œstradiol-17β—an interesting difference observed following single intramuscular injections of these three œstrogens

Œstrogen Levels During Lactation and the Puerperium

The œstrogen levels during lactation were low and were within the range normally found during the early part of a menstrual cycle After lactation ceased, the œstrogen levels began to increase slowly until the regular rise and fall found during a menstrual cycle was observed It may be significant that, after the period of lactation amenorrhœa, slight menstrual bleeding occurred when the œstriol and œstrone levels were each approximately 7 µg per 24 hours Such levels, when maintained for a period, might represent the minimum amounts of œstrogens required for stimulating endometrial growth, and yet, being within the range normally found at menstruation (Brown 1955b), they might make the stimulated endometrium unstable and precipitate menstruation

During the first menstrual periods after delivery, ovulation took place, but during the first two periods the luteal phases were abnormally short (8 and 10 days) This is contrary to the belief that the luteal phase always lasts about 14 days It is possible to envisage a luteal phase so evanescent that it cannot be detected By all the usual criteria such a menstrual cycle would be considered anovular, and it may well be that brevity of the luteal phase is the explanation of some of the apparently anovular cycles following delivery The third menstrual cycle appeared to be normal in all respects, and during this cycle the urinary œstrogen levels were almost the same as those found during the menstrual cycle preceding pregnancy This is a further example of the constancy in the pattern and amounts of œstrogens excreted during different menstrual cycles

Summary

The urinary excretion of œstriol, œstrone, and œstradiol-17β during conception, pregnancy, the puerperium, lactation, and the recommencement of menstruation has been measured in women A new chemical method of estimation was employed The results are discussed

I wish to thank Prof G F Marrian, F.R.S, and Prof R J Kellar, for their interest in this work. I am also grateful to the wives of colleagues who contributed the urine specimens, and especially to the one who made possible the complete study over a period of 17 months I am also indebted to Mr H A F Blair and Miss Janet Mackie for their skilled technical assistance

"General education is bound to differ according to the different lines of specialisation being followed It is no good whatever thinking that by laying on a course in literature and a course in current affairs it is possible to give both your scientists and your classics the general education which they need in addition to their special studies What you must try to do is to make them see their own line of study as one amongst many, and make them see where it stands in the general fabric of human knowledge You must persuade or cajole or force your scientists to write English coherently You must make them see that there are other approaches to reality than that of quantity and experiment, and get into their heads some appreciation of literary and artistic and moral values You must make them see how science has affected human life and give them enough history to enable them to do this general education in its profoundest sense is an essential part of specialist education"—H D P LEE, M.A., headmaster, Winchester College Report of Home Universities Conference, 1955 p 19 infants (Billing et al 1954) The action of large doses of vitamin K analogues may be to increase hæmolysis (Allison 1955), or to reduce further the liver's capacity to handle bilirubin

---

† The pregnanediol measurements were kindly performed by Dr A Klopper using the method of Klopper, Michie, and Brown (1955)

Summary

Premature babies given a total of 30 mg of synkavit intramuscularly after birth showed a significantly greater hyperbilirubinæmia on the fifth day of life than those given a single injection of 1 mg

It is suggested that routine use of the smaller dose would reduce the incidence of kernicterus of prematurity

We wish to thank Dr B E Schlesinger for permission to publish Miss D Walker for the bilirubin estimations, and Sister E Edwards for her cooperation

BONE-MARROW IN ANKYLOSING SPONDYLITIS *

E M Kingsley Pillers
M A, M D Camb, D C H
DAMON RUNYON RESEARCH FELLOW, DEPARTMENT OF RADIOTHERAPEUTICS, UNIVERSITY OF CAMBRIDGE

John Marks
M A Camb, M D Lond, M R C P
UNIVERSITY ASSISTANT PATHOLOGIST TO ADDENBROOKE'S HOSPITAL, CAMBRIDGE

Patients with ankylosing spondylitis may be unusually susceptible to the development of leukæmia as a long term effect after X-ray treatment to the spine (Court Brown and Abbatt 1955, van Swaay 1955), but we have not been able to find any published description of the bone marrow in ankylosing spondylitis either before or after X ray treatment We therefore report here the bone marrow findings in 18 patients before treatment and 10 patients after one or more courses of irradiation of the spine

Methods

About 0 25 c cm of bone-marrow was aspirated with a Turkel needle from the manubrium sterni, and smears were made directly on to clean glass slides in the usual way and stained with Leishman's stain Differential counts of 1000 cells were made on each specimen of bone marrow

Material and Results

28 patients were diagnosed as having ankylosing spondylitis, with typical clinical criteria and radiological findings, and all responded well to X-ray therapy Their hæmoglobin was within normal limits except in case 7, who had mild anæmia (Hb 10 2 g per 100 ml) The clinical details, bone marrow findings, and previous radiotherapy are shown in tables I and II The erythrocyte sedimentation rate (E S R) (Wintrobe correction to 45% hæmatocrit) was also included when this investigation had been made The cellularity of the bone marrow smears, judged from the cell density of the stained specimens, was normal in 17 cases and hypercellular in 11 This increase in cellularity affected all the formed elements of the bone marrow, and the myeloid and erythroid cells both showed normal maturation Lymphocytes and megakaryocytes were present in normal proportions, and the myeloid/erythroid ratios were within normal limits The only abnormalities detected were plasmacytosis and eosinophilia in some of the bone marrow smears

TABLE I—BONE MARROW FINDINGS IN ANKYLOSING SPONDYLITIS NOT TREATED BY IRRADIATION

Case no	Age (yr)	Sex	Yr since 1st symptom	E S R	Cellularity	Eosinophils (%)	Plasma cells (%)	Myeloid/erythroid ratio
1	27	M	3		H	6 1	0 9	8 1/1
2	38	M	5		C	14 6	1 0	3 1/1
3	49	M	2	35	C	3 5	0 8	5 1/1
4	52	M	5	29	H	3 3	0 2	3 2/1
5	24	M	3/4	18	C	3 8	1 5	2 4/1
6	27	M	4	1	C	2 3	1 1	4 1/1
7	44	M	3	32	H	1 0	2 1	2 6/1
8	47	M	20	29	C	2 5	0 7	2 4/1
9	30	F	4	7	C	3 0	1 4	4 2/1
10	30	M	1/2	4	C	2 1	1 3	4 9/1
11	27	M	4	29	H	4 0	1 7	5 4/1
12	42	M	14	37	C	12 7	3 8	3 5/1
13	38	M	2	21	H	5 1	2 7	2 0/1
14	59	M	7	39	C	3 7	0 9	4 7/1
15	38	M	14	24	C	3 6	2 2	3 4/1
16	61	M	5	20	C	1 5	3 5	5 0/1
17	42	M	15	25	C	8 4	1 6	4 6/1
18	47	M	4	33	H	2 1	3 1	2 8/1

The results of the bone marrow findings are summarised in table III, which shows that 10 patients had an increase in plasma cells and 4 had an increase in eosinophils in the bone marrow

TABLE III—SUMMARY OF BONE MARROW FINDINGS

Group of patients	Plasma cells		Eosinophil	
	Normal	Increased	Normal	Increased
With previous X ray therapy (table II)	6	4	9	1
With no previous X ray therapy (table I)	12	6	15	3
Total	18	10	24	4

Discussion

Marrow hypercellularity was found in 5 of the 10 patients who had received previous X ray treatment and in 6 out of 18 patients who had had no previous irradiation, and thus bears no relationship to previous radio

TABLE II—BONE-MARROW FINDINGS IN ANKYLOSING SPONDYLITIS TREATED BY IRRADIATION

* Part of this work was done with the help of a research grant to E M K P from the Medical Research Council

proposed by Morton and Wylie (1951), was shown by O'Mullane (1954) to be theoretically safe in the presence of passive regurgitation We induce anæsthesia with the patient lying flat on a tipping-table If the patient vomits she can be tipped into the Trendelenburg position Should regurgitation occur after the patient is completely paralysed, a similar position can be adopted Provided that the patient is completely paralysed and apnœic any regurgitated fluid will tend to drain out of the mouth, and since respiration has stopped such fluid will not be sucked into the chest The use of a laryngoscope and an efficient suction apparatus enables the pharynx to be cleared rapidly, and intubation is then performed

The equipment required is the standard anæsthetic equipment with a reliable mechanical sucker The labour-ward bed must be capable of being rapidly tipped into the head down position It is vital that, before anæsthesia is induced, the anæsthetist should check the machine, the laryngoscope, the suction apparatus, the inflatable cuff of the endotracheal tube, and the tipping mechanism of the table

Atropine sulphate gr $^1/_{100}$ (0 65 mg) is given intramuscularly twenty minutes before the operation is started In emergency it can be given intravenously

A Gordh needle is inserted into a vein on the dorsum of the hand and strapped into position, this is easily done since the veins are usually prominent owing to increased circulating blood-volume at term By means of this needle further doses of muscle relaxant can be quickly given should any difficulty in intubation arise Anæsthesia is induced with an oxygen rich mixture of cyclopropane, nitrous oxide, and oxygen, by a closed circuit with an intentional leak and with the absorber cut out As soon as the patient is unconscious succinylcholine chloride is given (5 mg per stone) through the Gordh needle At the onset of paralysis the lungs are gently inflated, adding extra oxygen to the gaseous mixture It is important to inflate gently, once in our experience vigorous inflation caused regurgitation of fluid into the pharynx O'Mullane (1954) has shown that any fluid present in the œsophagus after the crico pharyngeus muscle has been paralysed can, by vigorous movement of the lungs, be massaged from the œsophagus into the pharynx With the onset of full relaxation, laryngoscopy is performed and intubation carried out with a cuffed endotracheal tube The cuff of the tube is inflated to make a tight fit in the trachea, and artificial respiration is applied until spontaneous respiration has re established itself At this point gallamine triethiodide (5 mg per stone) is administered, and respiration is assisted as necessary, the carbon dioxide absorber being brought into the circuit

A light plane of anæsthesia is maintained with cyclo propane, nitrous oxide, and oxygen Additional doses of gallamine triethiodide may be required At the end of the operation the endotracheal tube is removed when the patient is becoming conscious, and tracheo bronchial toilet is performed On no account must the anæsthetist leave the patient until he is satisfied that she is fully awake and that her general condition is satisfactory

Discussion

To the anæsthetist a woman in labour presents problems similar to those in cases of intestinal obstruction All general-anæsthetic techniques in the latter cases are based on the use of a cuffed endotracheal tube to ensure a free airway, and it seems reasonable to use the same well-tried method in obstetric cases The advantages of using a tube are that once it is in position the anæsthetist has complete control of the airway for the remainder of the administration, that respiration can be easily assisted if required, and, most important of all, that gastric contents are prevented from reaching the trachea, bronchi, and lungs Further, as Mackenzie et al (1954) have shown, by this method a given plane of anæsthesia can be obtained with a smaller quantity of anæsthetic agent than otherwise In obstetric anæsthesia this is important

The mechanism whereby the fœtus obtains oxygen across the placenta is finely balanced, and any slight sub-oxygenation in the mother rapidly affects the fœtus At term, even under optimum conditions, mild anoxia may be present in the fœtus Any additional anoxia brought about by anæsthetic difficulties will tip the scale against the survival of the fœtus By the use of a cuffed endotracheal tube, adequate oxygenation can be provided at all times, and should fluid and debris appear in the pharynx the bronchial tree is protected

The danger of the technique described here arises during the induction of anæsthesia and before intubation By experienced, efficient, and gentle use of the laryngoscope and sucker, and by keeping a needle in one of the patient's veins, any difficulties that may arise can be overcome In a series of 100 cases (see table) trouble was experienced twice

100 CONSECUTIVE HOSPITAL CASES

Operation	No of cases
Mid-cavity forceps application	74
Cæsarean section	16
Antepartum hæmorrhage	3
Breach delivery	3
Eclampsia	1
Prolapse of cord	1
Extraction of dead fœtus	1
Delivery of anencephalic fœtus	1
Total	100

In the 1st of these 2 cases over vigorous inflation of the lungs in a paralysed patient squeezed fluid from the œsophagus into the pharynx This untoward event was treated by laryngoscopy and suction There were no ill results

In the 2nd case intubation proved difficult, and a further dose of muscle relaxant was necessary This case shows the value of the Gordh needle as a means of giving intravenous injections quickly

Criticism may be levelled against the introduction of a comparatively complicated technique But, like others (Gilliatt 1949, Jeffcoate 1953), we are certain that there is no place in the labour ward for the inexperienced anæsthetist

Conclusion

A cuffed endotracheal tube should be used in all cases where general anæsthesia is required for obstetric surgery

We wish to thank Dr G Edwards for encouragement and advice

TABLE I—RESULTS OF TREATING 1474 PATIENTS WITH ORAL STREPTOMYCIN

Age (yr)	No of cases	No of cases cured with			
		1 course	2 courses	2 courses	
				plus chloram phenicol	plus oxy tetra cycline
0–1	155	122	24	4	5
1–2	340	282	47	1	10
2–3	272	229	37	1	5
3–4	166	145	19	0	2
4–5	135	121	11	0	3
5–6	70	62	6	1	1
	1138	961 (84 4%)	144 (12 6%)	7	26
Over 6	336	306 (91%)	25 (7 5%)	1	4
Total	1474	1267 (86%)	169 (11 5%)	8 (0 5%)	30 (2 0%)

4 patients (aged 5 weeks, 3 months, and 34 and 75 years) died within twenty-four hours of admission, and none of these received streptomycin Dysentery was a contributory cause of death in 3 other cases, but in only 1 case was streptomycin used

Streptomycin was given for five days in an unflavoured aqueous solution in equally divided doses at six-hourly intervals, patients younger than 10 years received 1 g daily and patients older than 10, 2 g daily Treatment was started as soon as the stool was known to be bacteriologically positive, usually within thirty-six hours of the patient's admission If the dysentery was severe or the diagnosis was almost certain on epidemiological grounds, treatment was started soon after admission and at least one specimen of fæces had been collected

During the acute phase of the illness, the patient was given a fluid and light diet which was regulated according to age, general condition, and severity of the illness, and this was followed by a low residue diet until discharge from hospital Carriers received a normal diet If more than one course of streptomycin (or any other antibiotic) was required, vitamin B_1 was added to the diet during the additional course and for a few days afterwards In only 12 cases was intravenous fluid replacement necessary

After treatment, the patients were kept under surveillance for a short period and were not discharged unless at least three consecutive bacteriological examinations of fæces in the week after treatment had proved negative For patients returning to other hospitals, institutions, or nurseries, the minimum requirement was six consecutive negative examinations

Results

Although no direct comparison is possible, table I shows that the results in the under 6 age-group, which accounts for more than three quarters of the total number of cases, are an improvement on the previous sulphonamide series Of the 1138 cases in this group, 961 (84 4%) were cured by one five-day course of streptomycin, whereas comparable success was obtained only after two seven-day courses of sulphonamide, when 84% of 170 cases were cured

Table II shows how the results varied throughout the five year period, the proportion of cures after one course of streptomycin dropped by about 10% in both age groups during this period, but the results in 1953–54 were still better than those of the sulphonamide treated series Furthermore in 1953–54 a second course continued to cure most of the cases which were not bacteriologically cured after one course This does not suggest that bacterial resistance is as formidable a problem as might be expected, indeed, the comparatively poor results in the under-6 age group in 1953–54 may well be due to the fact that a larger number of cases were dealt with in a shorter period (one year), leading to overcrowding of the dysentery wards and greater danger of reinfection In a few instances, after apparent cure there was direct evidence of reinfection, patients had exacerbation of symptoms, shigellæ reappeared in the stools, and, more positive proof, strains of the organism were isolated which had not been present previously

Effects of Treatment on Different Types of Shigellæ

Clinical distinction of the illnesses produced by the several types of shigellæ is well-nigh impossible, but, in this country at any rate, the more severe infections with greater constitutional upset and often meningism, are likely to be produced by *Sh flexneri* The clinical response to oral streptomycin was usually rapid irrespective of the type of organism, and indeed the results from the bacteriological viewpoint are equally satisfactory, as table III shows

TABLE II—VARIATION IN RESULTS OF TREATMENT DURING THE FIVE YEAR PERIOD 1949–54

Period	Age (yr)	No of cases	No of cases cured by streptomycin with		
			1 course	2 courses	2 courses plus C or O
1949–51 (2 yr)	Under 6	418	371 (89%)	42 (10%)	5 (1%)
	Over 6	132	128 (97%)	3 (3%)	1 (1%)

C = chloramphenicol O = oxytetracycline

made in physiological saline solution Racks were held in a 37°C water bath so that the columns of reaction mixtures were about two thirds submerged Readings were made at intervals against the black background of an agglutination viewing-box A hand lens (× 5) was used to extend the range of particle visibility

Recording of Results

An arbitrary choice of symbols for recording degrees of flocculation is unavoidable For our detailed records we used a range of plus signs from ++++, indicating complete flocculation with sedimentation to the bottom of the tube, down to ±, indicating fine particulation only just detectable with a hand lens In addition, various degrees of opalescence were noted For the sake of clarity records presented in tables I–III have been simplified, and the symbols have the following meanings

+++	Complete or almost complete flocculation
++	Floccules uniformly distributed and easily visible to naked eye
+	Fine particles visible with hand lens—includes particulation ranging from that on verge of naked eye visibility to that only just visible with lens
op	Opalescence of any degree greater than that of the antigen saline control mixture
–	No sign of any reaction

It should be emphasised that the flocculation is just as easy to read as a routine agglutination test with suspensions of bacteria, and that the adoption of a titration end point analogous with " standard agglutination " would present no difficulty

To avoid possible confusion dilutions of antigens and antisera shown in the tables represent the initial dilutions before mixing Actual dilutions in the reaction mixture were of course twofold higher

Experimental Results

The design and scope of the experiments recorded were necessarily conditioned by the rigorously limited capacity of our small laboratory to produce antigens The production of a few ml of a single virus type antigen utilises our full resources for a fortnight, and, as nothing is yet known about the effects of storage, it was considered unwise to accumulate batches for experiments on a more adequate scale

Cross test with Brunhilde and Lansing

The first flocculation of poliomyelitis virus took place in the experiment recorded in table I The speed of visible flocculation of Brunhilde antigen with the homologous serum at 1 in 5 dilution raised, at the time, serious doubt of its validity as a specific reaction, but it is now known to reflect the phenomenon of optimal proportions precipitation (Dean and Webb 1926) The Lansing reagents did not particulate, though the development of opalescence markedly in excess of that shown by antigen control mixtures was unequivocal There are two obvious reasons for this weak Lansing reaction Reference to the rabbit immunisation schedule shows that the amounts of Lansing virus inoculated were only a fraction of the amounts of Brunhilde and Leon viruses given, later experience has shown that such a small antigenic stimulus was unlikely to provoke a satisfactory antibody response Even with a very potent antiserum it is unlikely that the Lansing antigen would have flocculated Results of infectivity titrations on the two virus concentrates were

Brunhilde antigen TCD 50/ml = $10^{-7\cdot2}$
Lansing " = $10^{-4\cdot8}$

On the basis of tissue culture infectivity, therefore, the Brunhilde antigen was 250 times more concentrated than the Lansing antigen As all efforts to improve the yield of Lansing virus from HeLa cell cultures failed, it was decided to abandon this strain temporarily and to continue the investigation with Brunhilde and Leon viruses

TABLE I—CROSS TESTS WITH BRUNHILDE AND LANSING REAGENTS

Antigens	Period of incubation (37°C)	Brun serum 1/1	Brun serum 1/5	Lans serum 1/1	Lans serum 1/5	Antigen controls
Brunhilde	5 min	op	++	–	–	–
	2½ hr	++	+++	–	–	–
Lansing	5 min	–	–	op	op	–
	2½ hr	–	–	op	op	–
Serum controls		–	–	–	–	–

For explanation of symbols see text

Chess board Titration of Brunhilde Reagents

The titration recorded in table II was made to study the effects of dilution of reagents and the period of incubation of reaction mixtures Reactivity of the serum at dilutions greater than 1 in 40 was not expected, so the dilution range used was too limited to give the serum end-points The reaction showed the characteristics of precipitation such as occurs in many serum - antiserum systems rather than of bacterial agglutination It is clear that antigen concentration was the dominant and critical factor, beyond 1 in 8 dilution no trace even of opalescence was discernible, and for practical tests only the antigen undiluted or at 1 in 2 dilution would have been satisfactory The progression of the reaction throughout the four-hour period of observation emphasises the importance of the relative proportions of antigen and antibody Optimal-proportions precipitation was evident in each antigen dilution row with well marked inhibition in the region of antibody excess Indeed it is apparent that, even with a good antigen, flocculation may be absent with very potent sera unless the latter are diluted sufficiently to extend beyond the zone of inhibition The occurrence of flocculation through a wide range of serum dilutions indicates the possibility of comparative serum titrations by means of the reaction

TABLE II—CHESS BOARD TITRATION OF BRUNHILDE REAGENTS

Time of incubation at 37°C	Brunhilde antigen dilution	Brunhilde serum dilutions 1/1	1/5	1/10	1/20	1/40	Antigen controls
½ hr	1/1	op	+	+	+	+	–

Cross-tests of Brunhilde and Leon by Chess board Titrations

Preliminary experiments with a Leon virus antigen showed that it was flocculated by various dilutions of the Leon antiserum and not at all by Brunhilde serum An extensive cross test using chess board titrations was therefore made

The results of the final reading after 4 hours' incubation at 37°C are presented in table III They afford a clear demonstration of the type specificity of the flocculation reaction The occurrence of opalescence, however, in the most concentrated cross type mixtures is interesting It may be due to contaminant antigenic material derived

RAPID TEST FOR HEPATOLENTICULAR DEGENERATION

H. A. RAVIN
M.D. Harvard
RESEARCH FELLOW OF THE NATIONAL FOUNDATION FOR INFANTILE PARALYSIS

From the Department of Biochemical Research, Institute of Neurology, Queen Square, London

THE definitive diagnosis of hepatolenticular degeneration (Wilson's disease) rests upon the demonstration of the following specific biochemical or metabolic abnormalities: increased urinary excretion of copper (Cumings 1951) and amino-acids (Uzman and Denny-Brown 1948), a low serum-copper level (Cumings et al. 1955), a low serum cæruloplasmin level (Scheinberg and Gitlin 1952), and low serum-copper oxidase activity (Bearn and Kunkel 1952).

These determinations are so tedious, exacting, or costly that they are generally made only in special neurological or research centres and even then are usually reserved for cases where clinical suspicion is high. As a result the correct diagnosis of hepatolenticular degeneration is often deferred for many months, until the inexorable progression of signs and symptoms makes the diagnosis clear on clinical grounds alone. This is far too late for optimal results of therapy, however, since copper-complexing agents cannot be expected to reverse well established functional deficits, although they may arrest or significantly retard the progression of this disease.

Of the several characteristic biochemical findings in hepatolenticular degeneration the most consistently abnormal result, with the least overlap into the range of normal values, is the considerable decrease of serum-copper-oxidase activity (Bearn and Kunkel 1952). Apart from hepatolenticular degeneration, only an occasional case of frank nephrosis is associated with abnormally low serum-copper-oxidase activity (Markowitz et al. 1955). A simple, rapid, and accurate colorimetric estimation of this enzymatic activity, requiring only standard laboratory equipment, is briefly outlined here.

Reagents

Commercial paraphenylene diamine is dissolved in acetone and converted to a salt by adding concentrated hydrochloric acid drop by drop until no further precipitate forms. The precipitate is collected on filter paper, washed with either dry acetone or ether, and dried in a desiccator. A 0.5% stock solution of paraphenylene diamine hydrochloride is prepared for use in the test and should be stored in a stoppered container in the cold (4°C). An increasing brown colour of the stock solution indicates deterioration, but the stock solution can be safely stored for about a week under the conditions described.

0.1 N acetate buffer (pH 6.0) is prepared by adding 10 ml. of 0.1 N acetic acid to 200 ml. of 0.1 N sodium acetate and is stored in the cold (4°C).

A 0.1% solution of sodium azide is prepared as a stock solution to stop the enzymatic reaction at the desired time. This solution requires no special storage and keeps indefinitely.

A 3% solution of sodium chloride is used as the diluent of the reaction mixture for measuring colour density, to prevent the turbidity attendant on dilution of serum with water.

Fresh serum, free from hæmolysis and turbidity, is preferable for accurate results; but a minimal degree of hæmolysis or slight turbidity may be tolerated, and the serum paraphenylene diamine-oxidase activity remains intact for at least two weeks at 4°C.

Method

All the determinations are made in duplicate. The reagents are warmed to room-temperature (25–27°C) before use.

0.1 ml. of serum is transferred accurately into the bottom of a 15-ml. capacity test-tube with a blood pipette. 1 ml. of the 0.5% paraphenylene diamine stock solution and 2 ml. of 0.1 N acetate buffer are added. A control for non-enzymatic oxidation is prepared at the same time in the very same way (including 0.1 ml. of serum) but with the further addition of 1 ml. of the 0.1% sodium-azide solution to inhibit enzymatic activity. The test-tubes are shaken for a moment to mix the reagents and immersed in a water bath at 37°C. After an hour's incubation the test-tubes are removed, and 1 ml. of 0.1% sodium azide is added immediately to stop enzymatic activity, with a brief shaking to mix the reagents.

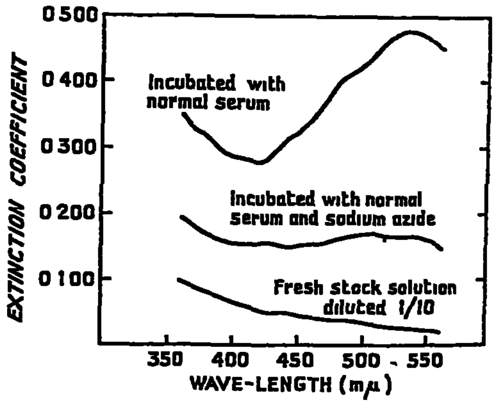

Fig. 1—Absorption spectra of solutions of paraphenylene diamine.

The colour density should be estimated within the first hour or two after completion of the incubation, because non-enzymatic oxidation of the substrate leads to gradual darkening of the solution. The reaction mixture is diluted to 10.1 ml., for quantitative estimation of colour density, by the addition of 6 ml. of 3% NaCl stock solution. The saline diluted solutions are analysed at 530 mμ (see fig. 1 for absorption spectrum) in cuvettes of 10 mm. optical path, with the sodium-azide inhibited control set at zero extinction.

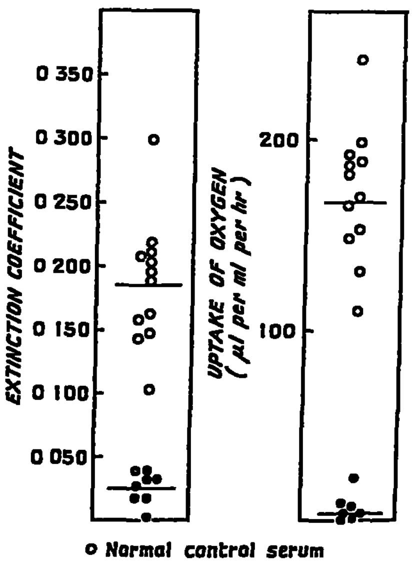

Fig. 2—Colorimetric and manometric measurements of copper-oxidase activity made in parallel on same samples of serum.

Results

The paraphenylene-diamine oxidase activity of serum is most readily expressed as the extinction coefficient of the diluted reaction mixture prepared and analysed under the standard conditions described above. Extinction readings and oxygen uptake obtained in 8 cases of hepatolenticular degeneration and in 14 unselected, control sera

We are greatly indebted to the National Fund for Poliomyelitis Research for a grant in support of Dr Churcher and a research expenses grant Expenses of the work have also been partially defrayed from financial support given to the department by the Medical Research Council Dr Lee is in receipt of a W H O fellowship Thanks are due to Dr Alistair Dudgeon for the sera from 2 cases of poliomyelitis, to Dr D A J Tyrrell for a sample of type 2 rabbit antiserum, and to Dr W Wood of Glaxo Laboratories Ltd, for supplies of 'Parker 199' medium

DURATION OF VASODILATATION AFTER LUMBAR SYMPATHECTOMY

A McPherson
M B Lpool, M R C P
LAMING EVANS RESEARCH FELLOW
ROYAL COLLEGE OF SURGEONS OF ENGLAND

A W L Kessel
M B E, M C, F R C S
CLINICAL RESEARCH ASSISTANT, INSTITUTE OF ORTHOPÆDICS, LONDON

In 1929 Lewis and Landis stated that in man the blood-vessels of the hand recovered their vasoconstrictor tone within four days after cervicodorsal sympathectomy They based their opinion on clinical observation, but since then many observers have investigated the blood-flow of the limbs after sympathectomy and have concluded that it returns to the preoperative level within weeks, or at most months, after operation Detailed plethysmographic studies have been made by Grant and Pearson (1938), Wilkins and Eichna (1941), Grayson (1948), Barcroft and Walker (1949), Lynn and Barcroft (1950), and Walker et al (1950), whose results confirm the transient nature of the vasodilatation in the persons they investigated

Many explanations for this recovery of tone after sympathectomy have been advanced, the more important of which may be summarised as follows

(1) The arteries become hypersensitive to adrenaline or to an unknown hormone (Meltzer and Auer 1904, Freeman et al 1934, Smithwick et al 1934, Grant 1935, White et al 1936, Ascroft 1936, Simmons and Sheehan 1939, LeCompte 1941)

(2) The muscle fibres of the arteries contract because of some "intrinsic property" of the muscle itself (Cannon 1937, Doupe 1943)

(3) Accessory sympathetic pathways which do not pass through the sympathetic trunk are left untouched by the operation (Richter and Woodruff 1945, Pick and Sheehan 1946, Skoog 1947, Boyd 1948, Ray and Console 1948, Boyd and Munro 1949, Wrete 1950)

(4) Regrowth of the damaged sympathetic axons may re establish connections with the blood-vessels (Lee 1930, Geohegan and Adair 1942)

A few investigators have stated that vasodilatation following sympathetic denervation may last a long time Adson and Brown (1929) reported persistently raised temperature of the toes after lumbar sympathectomy in man, and Ross (1946) wrote "The sympathetic denervation following a well-planned and correctly executed operation is permanent, as shown by sweating tests in addition to vasomotor reactions"

The present investigation of the blood flow and vasomotor reflexes of patients who had undergone lumbar sympathectomy for the relief of vascular symptoms (coldness, cyanosis, and chilblains) formed part of a larger investigation of the involvement of the autonomic nervous system in poliomyelitis (Kessel and McPherson 1953, McPherson and Kessel 1955)

Methods

The blood-flow in both feet of 14 patients (eighteen lumbar sympathectomies) was examined by venous-occlusion plethysmography Of the 14 sympathectomised patients 12 had poliomyelitis, 1 a birth palsy affecting the lower limbs, and 1 a hemiplegia during early childhood The sympathectomies were done by surgeons in several hospitals The controls consisted of 30 healthy people and 30 patients who had poliomyelitis but had not undergone sympathectomy The plethysmographs had volume recorders as described by Cooper and Kerslake (1951), and the investigations were made in a quiet draught-free, heat controlled room with the subject lying on a rubber mattress The lower limbs were immersed up to the thighs in water at a temperature of about 36°C for about thirty minutes before the insertion of the feet in the plethysmographs, to equalise their temperature as far as possible The investigations were made at room temperatures of 21–25°C, but in any one investigation the room temperature did not vary more than ±1°C The plethysmograph temperatures varied from 31 5 to 33 75°C, but in any one investigation did not vary more than ±0 25°C The difference in temperature between the two plethysmographs was never greater than 0 25°C Collecting pressures of 75–85 mm Hg were used throughout and were identical in both cuffs

Records were made at intervals of 5–15 seconds, and the investigation of each subject included measurements of blood-flow under three conditions (1) normal heat exchange (i e, the patient was covered by a light blanket at normal room temperature), (2) reflex vasodilatation (i e, after warming the arms in water-baths at 45°C and warming the body with a radiant-heat lamp until profuse sweating took place), and (3) reflex vasoconstriction (i e, while the warming was continuing, ice was suddenly placed on the forehead without warning)

The blood-flow was calculated from the average of twenty inflow curves except after reflex vasoconstriction, when it was calculated from the succeeding three inflow curves

The results of these tests are shown in table I

* Hemiplegic † Birth palsy

The means of the controls are given in table II together with the mean blood-flows of the sympathectomised patients

The blood-flows of all the subjects studied are shown in fig 1 The reasons for the small differences in blood-flow of healthy people and non sympathectomised patients with poliomyelitis are analysed in detail elsewhere (McPherson and Kessel 1955) For our present purpose these differences are ignored a fair number of pepsinogen and oxyntic cells were present The mucosa was infiltrated throughout with lymphocytes and plasma cells, and occasional eosinophil and neutrophil leucocytes The picture was that of an atrophic gastritis of moderate severity, with survival of a fair number of specialised cells "

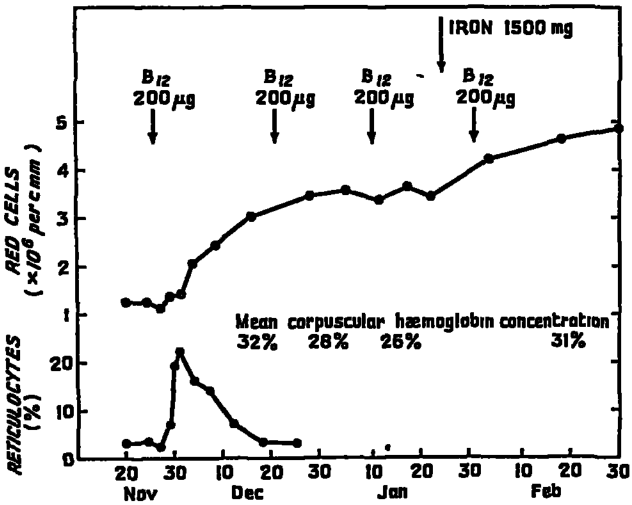
Fat balance —Normal 92% of the ingested fat was absorbed

Absorption of radioactive B_{12} —The patient absorbed 0 35 μg ^{58}Co labelled B_{12} from an oral dose of 0 6 μg given alone, and 0 39 μg from the same oral dose given fifteen minutes after the subcutaneous injection of 0 25 mg carbachol (carbamyl choline chloride) Similar amounts are absorbed by normal subjects (Mollin and Baker 1955)

Blood urea was 32 mg per 100 ml , and *serum proteins* 4 5 g per 100 ml (albumin 3 1 g , globulin 1 4 g)

Response to Treatment

The patient received an intramuscular injection of 200 μg vitamin B_{12} initially, and this was repeated on the 24th, 44th, and 75th days afterwards The response to this treatment is shown in the accompanying figure Three weeks after the first injection, the blood count showed signs of iron deficiency A course of 1500 mg saccharated iron was given intravenously The blood picture two months later was essentially normal (red cells 4,800,000 per c mm , hæmoglobin 14 0 g per 100 ml and P C V 46%)



The red cell and reticulocyte response to treatment with intramuscular vitamin B_{12} and intravenous iron 200 μg of vitamin B_{12} was given intramuscularly on each of the four occasions indicated

On admission to hospital on Nov 6 she ceased taking Glauber's salt but continued to pass four or five watery stools daily Four days after the first injection of vitamin B_{12}, the bowel action was normal Two weeks later her appetite had improved to the extent that she was able to take a full ward diet Her weight increased steadily and two and a half months after admission to hospital she had gained 1 st 4 lb The prolapse of her rectum was subsequently corrected surgically

Comment

These results indicate that the megaloblastic anæmia in this patient was due to vitamin-B_{12} deficiency, for her pretreatment serum-B_{12} concentration was low and her anæmia responded to treatment with B_{12} Deficiency of this vitamin may develop in patients after gastro-enterostomy who are taking an adequate diet (Mollin and Ross 1954) In these patients a blind antiperistaltic loop is usually present (Naish and Capper 1953) Such patients often have steatorrhœa and they are unable to absorb test doses of labelled B_{12}, excreting all or almost all of an oral dose of radioactive B_{12} in the fæces (Booth and Mollin 1955) In our patient, the gastro enterostomy functioned well, there was no steatorrhœa, and she was able to absorb normal amounts of test doses of labelled vitamin B_{12} This finding indicated that she had no intestinal lesion interfering with her ability to absorb vitamin B_{12} It also indicated that the patient was able to secrete normal amounts of intrinsic factor and was therefore not suffering from addisonian pernicious anæmia This was borne out by the gastric biopsy which did not show the gastric atrophy usually associated with this disorder

It is therefore clear that the deficiency of vitamin B_{12} in this patient was due to an inadequate dietary intake of the vitamin The patient's diet was, and had been for many years, grossly deficient in foods containing vitamin B_{12}, her sole source of vitamin B_{12} being her small daily allowance of milk, which did not exceed 200 ml per day, this is approximately equivalent to an intake of 0 4 μg of vitamin B_{12} (Gregory 1954) This proved to be quite inadequate to supply her requirements of this vitamin It seems unlikely that the constant intake of Glauber's salt interfered with intestinal absorption

Summary

A woman of 77 had lived on bread and margarine, tea, and potatoes for more than ten years She was found to have a megaloblastic anæmia which responded to vitamin B_{12} The B_{12} deficiency was due to the inadequate intake in the diet

Preliminary Communication

IRRADIATION OF PITUITARY FOR ADVANCED MAMMARY CANCER

In a series of 80 bilateral adrenalectomies for cancer of the breast, despite the most careful preoperative and postoperative treatment we have found that this operation carries a mortality of 6% This figure is comparable with those reported by Huggins [1] and Cade [2]

We do not consider that adrenalectomy is justifiable unless it gives a clear remission of the disease with complete alleviation of pain for at least a year. In our series such remission has only been obtained in 35% of cases

Hypophysectomy, while giving a greater proportion of successful results (probably 50%), still subjects the seriously ill patient to a major operation with a mortality of approximately 5% For these reasons an attempt has been made to find a safe procedure which would not add further to the patient's suffering, and which would at the same time be of value in the treatment of advanced cancer of the breast

At this hospital we have tried to destroy the pituitary gland completely by implanting unscreened radioactive gold Unlike other workers we have relied on smaller and, if necessary, repeated doses of β irradiation The gold seeds are implanted in the anterior part of the pituitary gland through a fairly small bore needle which is introduced into the sella turcica via the nose and sphenoidal sinus Extremely accurate visual localisation of the sella turcica is obtained by means of an image intensifier working in two planes, and only the most accurate positioning of the gold grains is accepted

During the past eighteen months 50 patients have been treated in this way with full biochemical and partly explained by the recovery of the paretic sympathetic nerve fibres and/or transmission in sympathetic synopses

---

[1] Huggins C Bergenstal D M *J Amer med Ass* 1951 147, 101 Huggins C Dao T L Y *Ibid* 1953 151 1388
[2] Cade S *Ann R Coll Surg Engl* 1954 15 71 Cade S *Brit med J* 1955 i 1

It is obvious that recovery from temporary injury to sympathetic nervous tissue cannot explain all the features of the recovery of arterial tone following some sympathectomies Some weeks or months after sympathectomy many patients have a blood-flow which is little different from the preoperative level, and in these patients it is often impossible to demonstrate any vasomotor reflexes Patients 6, 9, and 13, for example, had no vasomotor reflexes twenty five, sixteen, and twenty five months respectively after operation

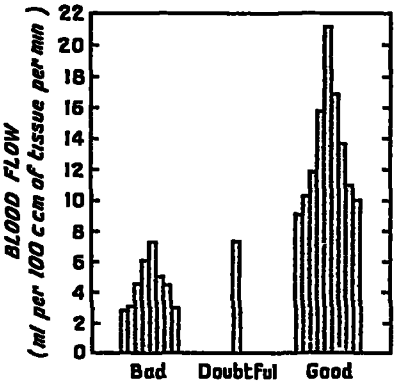

Fig 2—Comparison of blood flows and assessment of operations

Barcroft (1952) has suggested that the symptomatic improvement which follows sympathectomy, even though the arteries have regained their tone, can be explained by the protection of the blood vessels from vasoconstrictor stimuli which these sympathectomies provide The results of the present investigation suggest that the situation is more complex than this Patient 12, for example, had a considerable and long-lasting improvement in his vascular symptoms, even though the vasomotor reflexes were still present Conversely, patient 9 had only a moderate and transient improvement in his symptoms, although no vasomotor reflexes could be demonstrated sixteen months after his operation

It is usually assumed that the absence of vasomotor reflexes definitely indicates that the blood vessels have been deprived of their sympathetic innervation Hertzman (1954), however, has stated that, in his experience, a negative reflex vasodilatation test is uncertain evidence of sympathetic denervation, and Lynn (1954) has described patients whose vasomotor reflexes were absent but whose sudomotor activity was still present in the same limbs The fact that in the present investigation the vasomotor reflexes in the feet were sometimes absent regardless of the quality of the operation is, perhaps, supporting evidence for the conclusions of Hertzman although it is unlikely that this is the entire explanation of the phenomenon The results reported here suggest that both the absence of vasomotor reflexes and the resting blood flow level must be considered together as criteria for the adequacy of the sympathectomy

2 of the adequately sympathectomised patients (nos 1 and 10) showed a decrease in the level of blood-flow after reflex heating Patient 10 showed the larger decrease in blood flow on reflex vasodilatation (5 8 ml. per 100 c cm of tissue a minute), and this was the patient who had all ganglia resected from T12 to L3 inclusive

The results of this investigation suggest that the statement, sometimes made, that a patient has 'had a sympathectomy," merely because an operation was done with this intention, is likely to be misleading Sympathectomy may be difficult even in the most experienced and skilled hands, and its effects on the circulation may be extremely variable Table III shows that technically good operations for lumbar sympathectomy produce a considerable increase in the blood flow in the feet, and this vasodilatation may last for as long as fifteen years Such operations can produce a persistent vasodilatation which is almost as great (90%) as the "maximal" vasodilatation produced by heating the arms and body of healthy people On the other hand, technically poor operations for sympathectomy produce no persistent vasodilatation

The results obtained from the small series of patients investigated in this study indicate that, when an adequate sympathectomy is done, the denervated blood vessels do not regain their tone

It is difficult to suggest what constitutes a good lumbar sympathectomy, but the results reported here support the view of Hertzman (1954) "we feel that the surgeon must do a practically total lumbar ganglionectomy in order to increase the incidence of therapeutic gains" It is unfortunate that operations for sympathetic denervation have become less popular because of the reported recovery of vascular tone following the operation The present investigation supports the opinion of Ross (1946) that, when a sympathectomy is adequate, the results are long-lasting Further support for this point of view is provided by the fact that most of the sympathectomies producing a lasting vasodilatation were done by one surgeon who always removes, when possible, all the lumbar ganglia

Summary

The blood-flow in the feet of 14 patients with paralysed limbs who had had a lumbar sympathectomy (eighteen operations on 14 patients) was measured by venous occlusion plethysmography These blood-flows were compared with two control groups consisting of 30 poliomyelitis patients who had not had a sympathectomy and 30 healthy people

Those operations for sympathectomy which were technically good produced a lasting dilatation in the blood-vessels of the feet

Those operations which were technically bad did not produce a lasting vasodilatation

Our thanks are due to Mr H J Seddon for his continual advice and encouragement, and the surgeons of the various hospitals, particularly Mr G W L Bonney, of the Institute of Orthopædics, who made it possible for us to examine their patients

World Population and Resources

A report by Political and Economic Planning London P E P Distributed by Allen & Unwin 1955 Pp 339 30s

ACCORDING to the latest figures since 1930 the world's population has risen by a third Can this increasing population be supplied with adequate food, fuel, and raw materials ? Can the less fortunate of those now living be brought up to a decent minimum standard ? Can the hopes of advanced countries for still higher standards be satisfied ? Can the 30 million or so people added each year to world population be supplied with all their requirements ? Can all these things be done together and can they be done soon ? In particular, how nearly attainable is a balance between world population and world resources ? And if attainable, how can it be maintained ? It is the aim of P E P (Political and Economic Planning) to " study problems of public concern, to find out the facts to present them impartially, and to suggest ways in which knowledge can be applied ," and the organisation has produced an admirable report on these formidable questions

While much is being done and more can be done to increase the world's supply of foods, materials, and resources, there is obviously a limit to their production Unless some holocaust befalls or unless effective measures are applied to limit population, it will go on increasing for some time at least, and probably at a progressively more rapid rate Few people view with anything but horror the prospect of a third world war, yet there can be no doubt that ' population pressure " is one of the main factors that lead to war The problems of world population and resources must therefore be an urgent concern of all , and the report is intended particularly to provide the factual, quantative basis for frank discussion of the problem It demands the special attention of the medical profession, whose triumphs over disease have led to an increasing measure of death control and an upsurge in population One of the report's main points is that in future death control should not be pressed on in isolation but should go hand in hand with birth-control ' If programmes of death control and of economic development are to be thrust upon the people of underdeveloped countries, these peoples must be given corresponding opportunity to catch up with advanced Western countries in birth-control " " A major challenge to science is the supreme importance of finding a simple, generally acceptable, and low cost method of birth-control suitable for use by illiterates in difficult climatic or social conditions "

There are many difficult aspects to these problems, not the least of which is the attitude of religious bodies Many of these issues are boldly tackled in the report, and on the religious question some recent words of the Pope are quoted " The Church is not unaware of these problems she is not indifferent to their anguishing aspects We urge Catholics to take an active part in the research and in the efforts which are made in this domain "

Keratoplasty

R TOWNLEY PATON, M D F A C S , surgeon director, Manhattan Eye, Ear, and Throat Hospital New York and London McGraw Hill Book Co 1955 Pp 270 £10 14s

IT is fitting at this time that a surgeon of such international repute as Dr R Townley Paton should write a comprehensive book on keratoplasty for particularly during the past two decades, enthusiasm and interest in indications and contra-indications for this operation and in a variety of surgical techniques has become considerable To this difficult task Dr Paton has brought his valuable and large experience as a surgeon, a director of research a clinical professor of ophthalmology and an administrator of the eye bank, a superb organisation to which many patients and surgeons owe much

The book is admirably written and the author describes lucidly and thoroughly the surgical techniques which he has found most practicable and effective The procedures used by other surgeons are discussed and the vast literature is judiciously reviewed and sifted Throughout the work, Dr Paton has kept a fine balance between the scientific and clinical aspects, and has clearly shown where these are complementary to each other

There are 29 excellent colour plates as well as half tone photographs , and the drawings of the author s operations are well executed by Miss Daisy Stilwell

Die endogenen Psychosen

das delphische Orakel der Psychiatrie KURT KOLLE professor of psychiatry and neurology in the University of Munich Munich Lehmanns 1955 Pp 48 DM 3 [illegible]

THIS oration was delivered in memory of Emil Kraepelin by the present professor of psychiatry in Munich on the fiftieth anniversary of the opening of the clinic with Kraepelin as its director Professor Kolle is vehement in his opposition to current trends in psychiatry he belongs to the old school and demands more direct and convincing evidence before he will approve psycho-analytic interpretations or accept the claims made for psychotherapy by some and for insulin by others in the treatment of schizophrenia The psychogenesis of affective psychoses is no more plausible to him than it was to Kraepelin and even Kretschmer goes further than Kolle will follow There is, of course much for the sceptic to gird against in modern psychiatry but Professor Kolle seems to be certain that, with few exceptions, what we know of this subject is no more than we knew twenty-five or more years ago Like other sturdy diehards, he makes shrewd thrusts and picks off foolish adversaries while the main body moves past him possibly in the right direction

Scurvy as a Skeletal Disease

H J VAN WERSCH, M D Utrecht Dekker & van de Vegt N V 1955 Pp 365

THIS book came about in a curious way In 1935 the author saw as a patient a girl of 18 with a peculiar bone disease which had been variously diagnosed as sarcoma, von Recklinghausen's disease, and Paget's disease A shadow in the upper part of the femur, which had led to the first diagnosis turned out to be a calcified subperiosteal hæmatoma from scurvy The appropriate treatment was instituted—six years after the onset of the disease—and the patient made a gratifying recovery During the German invasion of 1940–45, Dr van Wersch lost touch with his patient, who had again developed scurvy , but after the war further treatment with vitamin C produced improvement Inspired by his study of this patient, he wrote this book on scurvy in its clinical and laboratory aspects There is little new work, but the subject is dealt with at length The book is rather like a large and slightly uncritical M D thesis

Standard Atlas of Human Anatomy (*Descriptive and Regional* Vols I and II 3rd ed London Butterworth Amsterdam Scientific Publishing Co 1955 Pp 11[illegible]4 *72s 6d* the set) —The third edition of Prof M W Woerdeman s atlas is the first in which the two volumes have been issued together, and in response to the author s wish ' to keep in mind the unhappy economical situation of so many students " the publishers have used again the blocks of the first edition This means that a few unimportant errors in the plates are retained, but the justification lies in the price which is indeed low for so well produced an atlas Vol I deals with the locomotor system in 512 plates the other systems are contained in vol II, which has 642 plates Each plate depicts an individual specimen and does not show features derived from several dissections , it is suggested that the student can thus obtain an idea of the range of the normal by comparing his own work with the plates There are many diagrams showing the lines of pull of the muscles most of these are helpful, but some might be a little confusing The central nervous system and the heart are dealt with in detail, and there are some rather complicated diagrams of neural pathways The peripheral vessels and nerves are shown in a semi diagrammatic fashion bereft of all but their largest and grandest relations Colour is sparingly used, it being contended that the student is forced to look more carefully at a monochrome picture than at a coloured one The plates are clear accurate, and well labelled The terminology used is the B N A and now that the anatomical world has adopted a unified system of terminology based on the B N A this excellent atlas should prove even more useful than before to British students

TABLE II—ISOLATION FROM SAME SPECIMEN OF PAIRS OF *Staph aureus* DIFFERING IN REACTION TO PENICILLIN

—	No of pairs	Phage pattern of pair		
		Same	Doubtful (one of pair untypable)	Different
Old series (Fairbrother et al 1954)	13	6	2	5
New series	12	5	3	4
Total	25	11	5	9

(10–50 colonies) gave uniform results Occasionally, however, slight differences among the colonies were detected in either production of pigment, size, or zone of hæmolysis on a blood-agar plate, on rare occasions a few colonies were found in the clear zone around an antibiotic disc Sensitivity tests often proved regular, but in a few cases differences in behaviour towards the various antibiotics were observed (tables II and III)

Despite the large number examined, differences in the reaction of individual colonies to penicillin were observed with only 12 cultures prepared from the same lesion Of these 12 pairs, 5 strains gave the same phage pattern, 4 proved to be quite different, and in 3 pairs one at least of the strains proved to be untypable

In the two series of investigations 25 pairs were isolated, and 11 of these gave the same phage pattern it is reasonable to assume that they had originated from the same parent strain in vivo In 5 of 25 pairs the typing results were inconclusive The reaction to penicillin of the organisms originally responsible for the infection could not be determined, and it was therefore impossible to identify the variant strains The pairs of *Staph aureus*, although reacting differently to penicillin, behaved consistently towards the other antibiotics

During this work a comparable variation in reaction of individual colonies to other antibiotics (chloramphenicol, tetracyclines, or streptomycin) was also observed on a few occasions (table III) In 6 of 15 infections variant strains seem to have developed in vivo This problem was, however, left for further study

IN-VITRO PRODUCTION OF VARIANT STRAINS

As there are serious practical limitations to the study of the mode of development of variant strains of *Staph aureus* under natural conditions, further investigations were made into the appearance, under experimental conditions, of (1) penicillin sensitive variants from apparently pure cultures of penicillinase-producing strains of *Staph aureus*, and (2) penicillinase producing variants from apparently pure cultures of penicillin-sensitive organisms

Development of Penicillin sensitive Variants from Penicillinase producing Strains

Although many workers have claimed that penicillinase-producing strains of *Staph aureus* are permanently resistant to penicillin, there is now much evidence that they are very unstable (Barber 1949, Fairbrother et al 1954) Further tests demonstrated the instability of penicillin resistant strains of *Staph aureus* grown in a water bath at 44°C

Penicillin resistant colonies of *Staph aureus* were selected from recent cultures of infected material, subcultures were prepared on agar plates, and, after overnight incubation, sensitivity tests were made on 10–20 discrete colonies If all proved resistant to penicillin, a subculture of a discrete colony from the first subculture was prepared and again sensitivity tests were made on individual colonies If these proved satisfactory one of these penicillin resistant colonies was seeded into 10 ml of broth and incubated in a water bath at 44°C, coagulase and penicillinase tests were done at the same time to ensure that a true penicillin resistant strain was being investigated Serial subcultures in broth were made usually every one to three days, to give a final total of 20, at intervals plate cultures were also prepared, by means of a large loop, for colony tests of penicillin sensitivity by the strip technique

TABLE III—ISOLATION FROM SAME SPECIMEN OF PAIRS OF *Staph aureus* DIFFERING IN REACTION TO STREPTOMYCIN, CHLORAMPHENICOL, OR TETRACYCLINES

Phage pattern of pair	No of pairs isolated
Same	6
Doubtful (one of pair untypable)	5
Different	4

14 penicillin resistant strains of *Staph aureus* were examined in this way (table IV) and 10 were found to produce penicillin sensitive variants Of the total of 21 strains so far examined, 14 produced variants In some cases the penicillin sensitive variants were detected after only one or two subcultures, but in the case of other strains the variants did not appear until later In some cases the penicillin sensitive variants exhibited definite colonial changes, the colonies being larger and less pigmented, but in other cases the colonies appeared to be identical with those of the penicillin resistant strains In all cases the phage patterns were either identical or showed only minor variations

TABLE IV—PRODUCTION OF PENICILLIN SENSITIVE VARIANTS FROM PENICILLINASE PRODUCING STRAINS OF *Staph aureus* BY INCUBATION AT 44°C

—	No of strains tested	Incidence of penicillin sensitive variants
Old series (Fairbrother et al 1954)	7	4
New series	14	10
Total	21	14

Thus it appears that penicillin sensitive organisms readily develop from apparently pure cultures of penicillinase-producing strains of *Staph aureus* during growth at 44°C, which is about the highest temperature allowing active growth of this organism The intermittent subculturing of a single loopful of a broth culture and the examination of about 100 colonies during 20 subcultures do not constitute particularly exacting tests for the detection of penicillin sensitive variants, so probably, if more rigorous methods had been used, penicillin sensitive variants might have been detected in every case

Appearance of Penicillinase producing Variants in Cultures of Penicillin sensitive Strains of Staph aureus

While there is no doubt about the instability of penicillinase producing strains of *Staph aureus*, there is as yet no unequivocal report of the isolation of penicillinase producing organisms from apparently pure cultures of sensitive strains

Initially abortive attempts were made to achieve this by growing penicillin-sensitive organisms in media containing small amounts of either penicillinase or penicillin Subsequent subculture on to agar plates and examination of discrete colonies failed to reveal any penicillinase-producing variants It was then decided to try serial subculture in broth at 33–35°C

Sensitive strains of *Staph aureus* which did not produce penicillinase were used, and a discrete colony from a plate, seeded with a discrete colony from the primary culture, was used as the original inoculum After inoculation of the broth an agar plate was seeded, and all the colonies tested from this proved to be penicillin sensitive In this way attempts were made to ensure that a pure penicillin sensitive culture was being investigated At least 20 serial subcultures were made, and at intervals colony tests were made

8 strains were thus tested, but on no occasion was a penicillin-resistant colony detected (table V)

Timothy grass . . .

STAPHYLOCOCCI HARBOURED BY PEOPLE IN WESTERN HIGHLANDS OF NEW GUINEA

PHYLLIS M. ROUNTREE
D.Sc. Melb., Dip. Bact.
From the Fairfax Institute of Pathology, Royal Prince Alfred Hospital, Sydney, Australia

NUMEROUS investigators have reported a steadily increasing prevalence of penicillin-resistant strains of *Staphylococcus aureus* in civilised communities (e.g., Barber and Burston 1955, Ternal and Chabbert 1955). Many of these strains appear to have been detected in hospital environments, but there is still some debate on their origin since penicillinase-producing strains may also be found in people who have not been admitted to hospital. There are fewer reports of the antibiotic resistances of coagulase-negative staphylococci, but 50% of a series of 444 strains of this kind isolated in this hospital in 1954–55 were penicillin-resistant.

Unfortunately few collections of staphylococci isolated before the introduction of penicillin are available for study. Anderson (1946), however, examined 396 strains; of these 281 were coagulase-positive and sensitive to penicillin, while of the remaining non-pathogens a few were penicillinase producers. Furthermore there are now few parts of the world where penicillin has not been freely used. Hopps et al. (1954) reported that 43 strains of *Staph. aureus* obtained from skin lesions of Dusuns of North Borneo were penicillin-sensitive, although 3 produced penicillinase. Similarly 14 strains from skin lesions in people indigenous to tropical Mexico were penicillin-sensitive, 5 being penicillinase producers. In both these groups of people antibiotic usage was minimal. It should be noted, however, that both groups have a long history of contact with white people.

In the Wabag region of the Western Highlands of New Guinea lives a group of people who have had very little contact with civilisation (Elkin 1953). Their existence was unknown before 1910; the area in which they live was first penetrated in 1934, and since that time no more than 30 white people have had contact with them—and even such contact has been slight (Macintosh 1955).

These Wabaga, numbering approximately 200 000, live in a mountainous region 85 by 100 miles in area in discrete family units, not in villages but in homesteads. They are exceedingly primitive and have a minimum of material culture. Ethnically, they appear to be distinct from their mountain neighbours and from the Papuans inhabiting the coastal regions, but their origin is still undecided. In 1946, after the area had been closed since 1938, administrative buildings and an airstrip were built in one locality (Wabag), and in 1949 a native hospital was established. However, as the Wabaga are free from yaws, there has been no mass campaign of penicillin therapy in the region.

The recent Nuffield expedition to the region provided an opportunity to take nasal swabs from some of these people. The 120 men swabbed were scattered throughout the area. So far as could be ascertained, none had ever received any antibiotics. Two groups of swabs were taken from men in areas where contact had been limited to the occasional passage of administrative patrols. The remainder of the swabs were taken from men in areas where there had been some contact with the administration and missionaries.

Methods

The swabs were inoculated immediately on to nutrient-agar slopes in screw-capped bottles and dispatched by air to Sydney for examination.

Representative inocula from the slopes were transferred to blood-agar plates. After incubation, single colonies of various degrees of pigmentation were picked for further study. Not more than three colonial types were isolated from any one swab.

Tests for sensitivity to penicillin, streptomycin, oxytetracycline, chlortetracycline (aureomycin), and chloramphenicol were carried out in the first place by a disc-plate method (Rountree and Thomson 1949, 1952). Strains showing the same amount of inhibition as the control Oxford H strain were regarded as sensitive. Strains showing less inhibition than the control were tested by a tube method. With penicillin small inocula of 0.02 ml. of a 10^{-4} dilution of an overnight broth-culture were used to inoculate serial dilutions of the antibiotic in 1 ml. broth. With the other antibiotics, 0.02 ml. of undiluted broth-cultures were used as inocula. Results were read after eighteen hours' incubation at 37°C.

Strains partially or completely resistant to penicillin by the plate method were tested for penicillinase production by the method of Voureka and Hughes (1949).

Certain strains were tested for ability to ferment glucose and to give the Voges-Proskauer reaction (Shaw et al. 1951).

Results

Pathogenic Staphylococci

Only 23 carriers of coagulase-positive *Staph. aureus* were found—a carrier-rate of 19.1%. However, the high proportion of cultures yielding coagulase-negative strains indicated that carriers of pathogens had not been missed because methods of collection or transport of the material were unsuitable for the survival of staphylococci. All strains produced α toxin, but no β-toxin was detected on 5% sheep-blood-agar plates. All strains were sensitive to the five antibiotics.

The strains were phage-typed with the results shown in table I. The seventeen patterns observed among the 23 strains are found in strains isolated from civilised communities. It was noted, however, that 8 of the strains reacted only when the phages were applied in high concentration, suggesting some minor difference in their behaviour compared with the strains normally examined

TABLE I—PHAGE-TYPE DISTRIBUTION OF STRAINS OF *Staph. aureus*

Phage group	Phage pattern	Number of strains reacting at: R.T.D.	Number of strains reacting at: 10^{-3}	No. in group
I	52/52A/79/80		1	7

that the risk of allergic reactions was too great Superficial burns cleaned and treated soon after the accident should not need prophylactic antibiotics but if inflammation spreads around the burn within the first few days it is often the work of the hæmolytic streptococcus, and usually responds rapidly to rest and penicillin Localised infection by *Staphylococcus aureus*, hæmolytic streptococci, and gram-negative organisms is also a hazard later on in cases in which sloughing and granulations supervene, but this is a problem better dealt with in hospital The advantages of the exposure method are greatest, probably, in treating superficial burns of the face—a site where dressings cannot easily be held in position, and where bandages require continual attention After careful cleansing of the burned areas, the corners of the nose, mouth, and eyelids are lubricated with soft paraffin, and the whole burn is allowed to dry as soon as possible These cases, in particular, should be referred for specialist treatment if at any time there is suspicion that the true skin is seriously involved

All our devices may fail to yield an accurate initial estimate of the severity, though accuracy increases with experience Few burns can be seen and assessed immediately by a plastic surgeon Those of us who see the moderate or severe burn only on rare occasions need not be embarrassed by having to modify our earlier views as the days go by and the slough becomes defined Where skin-grafting is necessary, the earlier it is done the better Nevertheless, in the present state of knowledge we must accept that the necessity cannot always be recognised at once In the doubtful cases an open mind for the first week or two allows a judicious change of policy without a recantation It will also obviate criticism of any particular method of treatment, where the reason for disappointment lies in the characteristics of the injury itself

Infantile Pyloric Stenosis

THE adoption of Rammstedt's operation of pyloromyotomy notably improved the results in infantile pyloric stenosis, and, with progress in the hospital care of infants, mortality-rates have sunk to about 2% in many clinics A discussion held at the Royal Society of Medicine[1] in 1951 revealed various preferences in the matter of preparation for operation, technique, and anæsthesia Some preferred medical management with atropine derivatives Nevertheless everyone reported good results, though DAVISON pointed out that the Registrar-General's figures still suggested a mortality for the country as a whole in the region of 10–15% He considered that treatment in a department where the nurses and doctors were accustomed to dealing with the condition was more important than the particular method used As family doctors now detect or suspect this not uncommon condition at a commendably early stage, its management seems to present few outstanding difficulties

Rammstedt's operation has now been in use long enough for some of the earlier patients to be having children This has stimulated interest in other facets of the natural history of the disease An increased liability to pyloric stenosis in the children of previously affected parents has been recognised for some time COCKAYNE and PENROSE[2] suggested inheritance by a recessive gene influenced by sex and birth order Further studies have shown that the ætiology may not be so simple MCKEOWN and MACMAHON[3] have examined the offspring of men and women who have recovered from infantile pyloric stenosis Adding the figures from CARTER and POWELL[4] and NEILSON'S[5] studies to their own Birmingham series, they found 14 "pylorics" amongst 203 children of affected parents—a high incidence of 6·9% Further search among records of their own and other centres revealed 33 instances of parent and child having this disease The affected parent was the mother in half of these, in spite of the well-known higher incidence in males Furthermore, examination of their fraternities showed that an even greater proportion of the children in these particular families suffered from the condition (42 out of 69 children) The conclusion drawn was that the increased risk of having affected children was not the same in all survivors, but was localised in certain families and was increased when the mother was the affected parent MACMAHON and MCKEOWN[6] have also studied the concordance in twins It used to be thought that identical twins would both be affected if either had the disease SHELDON[7] observed an exception, and others were described later by CARTER and POWELL[8] An environmental factor in the development of pyloric stenosis might account for this MACMAHON and MCKEOWN found in their series, which they believed to be more representative than earlier ones, that there was no increased concordance in monozygous twins compared with dizygous They support the suggestion of a postnatal environmental influence That the tumour itself usually develops after birth has been accepted for some time[9] GERRARD and his colleagues,[10] also working in Birmingham, have measured the size of the tumour in 51 cases and have confirmed an earlier finding of MCKEOWN et al[11] that its size is proportional to the age of the baby at operation The onset of symptoms was more rapid in the babies fed three-hourly than in those on a four hourly schedule The relative importance of inherited characteristics and postnatal influences can be assessed only by further inquiries along these promising lines

The number of particularly susceptible newborn children seems likely to increase as more survivors of infantile pyloric stenosis begin their families Prophylaxis of the condition by medical means may seem a wise course when the risk for each individual baby can be better assessed In this connection a paper by CRAIG[12] is timely He felt a contractile pyloric tumour in 17 out of 21 babies who were examined during the first two weeks of life for failure to thrive associated with possetting, regurgitation or vomiting Only 3 were operated on, and 2 had a typical hypertrophied pylorus All the others recovered promptly with gastric lavage Moreover, using precise time, since, in our experience, symptoms of kernicterus commonly develop on the sixth or seventh day and only occasionally on the fifth day

Following reports by Allison (1955) and Laurance (1955) that the administration of large doses of vitamin-K analogues to premature infants was potentially dangerous in relation to the development of kernicterus, we reduced the routine dose of synkavit given after birth from a total of 30 mg in the first seventy-two hours to 1 mg on the first day The effect of this change of dosage on the plasma bilirubin levels forms the basis of this report

Materials and Methods

Plasma bilirubin levels were estimated in two groups of premature babies

Group A consists of the 55 survivors of 72 infants admitted to the premature baby unit from September, 1954, to April, 1955, inclusive, 17 having died before the fifth day of life They received 10 mg of synkavit daily by intramuscular injection for three days There were 26 males and 29 females, 17 were twins, their birth weights ranged from 2 lb 5 oz to 5 lb 7 oz

Group B consists of the 51 survivors of 60 infants admitted from May to November, 1955, 9 having died before the fifth day They received a single injection of 1 mg of synkavit on the first day of life There were 30 males and 21 females 10 were twins, and there was one set of triplets Their birth weights ranged from 2 lb 3 oz to 5 lb 8 oz

Cases of hæmolytic disease due to blood group incompatibility were excluded from both groups

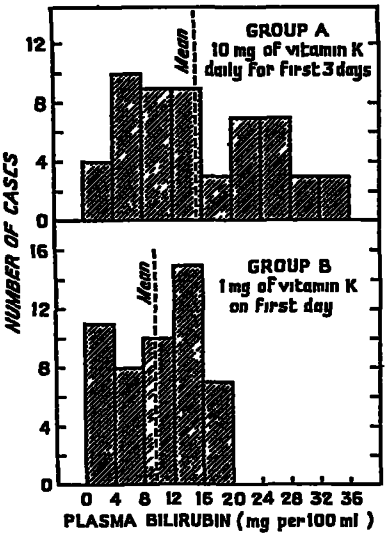
The two groups received the same routine care, apart from dosage of vitamin K

Plasma bilirubin levels were estimated in heparinised plasma by King's (1951) method Blood was obtained by puncture of a femoral vein

Results

The direct reaction with van den Bergh's reagent was negative in all the cases

The distribution of the plasma bilirubin levels in the two groups is shown in the accompanying figure The mean level in group A was 15 4 mg per 100 ml and in group B 9 7 mg per 100 ml The difference between the means (5 7) is four times the standard error of the difference (1 44) Thus there is a significant difference between the two groups



Distribution of fifth-day plasma bilirubin levels in premature babies according to dosage of vitamin K

The accompanying table compares the number of babies with a plasma-bilirubin level of 18 mg per 100 ml or higher in each group as a whole and when subdivided into standard birth weight ranges In group A the total is 21 of 55 (38%), whereas in group B it is 2 of 51 (4%) This difference is significant at the 0 1% level Further, it will be seen that the difference between groups A and B is reflected in each birth weight range

There were 2 deaths from kernicterus in group A one in a baby of birth weight 3 lb 10 oz and with a fifth day plasma bilirubin level of 34 mg per 100 ml, and the other in a baby of birth weight 4 lb 7 oz and with a plasma-bilirubin level of 22 mg per 100 ml 3 other babies had mild symptoms on the seventh day (lethargy and irritability when disturbed) which might have been due to kernicterus, their fifth-day plasma bilirubin levels were 24 4, 27 8, and 33 mg per 100 ml All 3 infants appeared normal at the age of 1 year

NUMBER OF PREMATURE BABIES WITH PLASMA-BILIRUBIN LEVELS OF 18 MG PER 100 ML OR HIGHER, ACCORDING TO WEIGHT AND DOSAGE OF VITAMIN K

Birth weight	Group A (30 mg vit K)		Group B (1 mg vit K)	
	No of cases	Plasma bilirubin 18 mg per 100 ml or higher	No of cases	Plasma bilirubin 18 mg per 100 ml or higher
3 lb 4 oz or less	9	5 (*55 5%*)	10	1 (*10 0%*)
Over 3 lb 4 oz to 4 lb 6 oz	23	10 (*43 5%*)	15	0
Over 4 lb 6 oz to 5 lb 8 oz	*23*	6 (*26 1%*)	26	1 (*3 8%*)
Total	55	*21* (*38 2%*)	51	2 (*3 9%*)

In group B there were no deaths and no baby developed symptoms suggesting kernicterus

Discussion

Premature babies tend to bleed in the first week of life (Smith 1954) It is usually advised that vitamin K be given to all premature babies after birth to prevent hypoprothrombinæmia, which is one factor producing the tendency to bleed Large doses of the vitamin (up to a total of 90 mg) have been used routinely in some centres

The present results show that the dose of synkavit given to premature babies after birth affects the degree of hyperbilirubinæmia on the fifth day of life The importance of this effect is shown by the fact that about 40% of the 55 infants given 30 mg of synkavit had plasma bilirubin levels of 18 mg per 100 ml or higher, and 2 died of kernicterus In hæmolytic disease of the newborn a plasma bilirubin level of 18 mg per 100 ml or higher is dangerous because of the possible development of kernicterus, and probably levels of this order are equally dangerous for all premature infants Certainly we have seen a small area of bile staining in the basal ganglia of a premature baby, not in this series, who died of an intercurrent illness and had a plasma bilirubin level of 17 8 mg per 100 ml a few hours before death

Only 2 of the babies given 1 mg of synkavit had a plasma bilirubin level of 18 mg per 100 ml or higher on the fifth day One of these babies had a birth weight of 4 lb 12 oz, and usually the reduction in the plasma-bilirubin levels in babies given the smaller dose of synkavit has been less marked in those with a birth weight over 4 lb 6 oz It must be remembered that fifth day plasma bilirubin levels are not necessarily maximal, and it is possible that a few babies given 1 mg of synkavit had levels above 18 mg per 100 ml either shortly before or after the fifth day

These findings indicate that a decrease in the incidence of kernicterus of prematurity could be anticipated if the practice of giving large doses of vitamin-K analogues to premature infants were abandoned Since it has been shown that one dose of 0 5–1 0 mg of vitamin K is as effective as larger doses in preventing postnatal hypoprothrombinæmia (Lehmann 1944), this dose might well be adopted universally for routine use

We have not investigated the mode of action of vitamin K in increasing hyperbilirubinæmia A reduced capacity of the liver to transform the indirect-reacting pigment, bilirubin, to direct reacting bile pigment is thought to be the major cause of the hyperbilirubinæmia of newborn

Among the 40 people who had stopped using their aids, the commonest reason given was noise and headache, 9 of them complained that the aid was too heavy Thus, the great majority of those who received the medresco aid were much better for it GETTES and TRACY remarked "Our general impression is that individuals who obtain employment and become deaf in the course of years usually retain their occupation and are helped to do so as the result of the provision of a hearing-aid On the other hand, deafness as such appears to make it difficult for some individuals to obtain employment, which difficulty is often overcome by the provision of a hearing-aid" They made no attempt to correlate the value of a hearing-aid with the causes of deafness From a medical rather than from a social point of view this information is, of course, of the utmost importance

KODICEK and GARRAD[3] have lately described a large survey of users of the medresco aid, and they included in their findings considerable detail about the relative values of the aid in different types and degrees of deafness They sent out 1459 questionaries to all patients who had been issued with an electrical hearing-aid by the ear, nose, and throat department at St Thomas's Hospital at least six months previously 964 replies were analysed The patients were placed in one of four main diagnostic groups according to the primary causes of deafness otitis media (29% were in this group), otosclerosis (41%), presbyacusis (senile deafness) (15%), and nerve deafness from other causes (15%) Thus, 70% suffered from conductive deafness, and the remaining 30% were about equally divided between cases of acquired nerve deafness and senile cochlear changes The otosclerotic group made the best use of the aid and seemed to get most help from it, wearing it both for work and pleasure The otitis media group was second best, as expected on clinical grounds These two groups accounted for more than two thirds of all the patients, yet only half of the 93 returned instruments came from patients in these groups An average loss of 60 decibels in the speech frequencies for both ears (by pure-tone audiometry) was taken as the dividing line between moderate and severe deafness, and it is interesting that those who were judged to be only moderately deaf were more critical of the aid, and used it less often and for fewer hours each day, than did patients with severe deafness Over half the employed people used their hearing-aids at work, but, from volunteered comments, it was clear that factors limiting the use of the aid at work were weight of batteries, background noise from clothes rub, and restriction of movement by the leads On the other hand, 19 patients volunteered the information that the aids had enabled them to stay at or return to work In reply to direct questions, over 90% said they found their aids helpful and that they had made their lives easier or more enjoyable The fact that 525 people failed to reply raises the question of the general applicability of the findings, and KODICEK and GARRAD think it probable that there was a larger proportion of satisfied patients among those who replied than among those who did not

However that may be, there are many thousands of people whose lives have been changed by the medresco hearing-aid When the National Health Service was introduced, the Government set out to produce an aid that would benefit the majority of deaf persons, at a reasonable cost they succeeded That is not to say there is no room for improvement there are very few hearing-aid users who would not welcome a less cumbersome "monopack" aid, and a preliminary trial has already been carried out with such a model It is only to be hoped that its general issue will not be too long delayed, although we are already warned that the earliest issues will be reserved, quite rightly, for children The transistor aids, with their lighter weight and longer battery life, offer attractive possibilities for the future, but they have yet to be put to the hard test of daily wear and tear, and it would be unreasonable to expect this latest modification to be applied to the Government aid until its rightful place has been carefully assessed As HELLER[4] puts it, "the advantages of transistor hearing aids lie in the realm of convenience and economy rather than in performance It is well to bear in mind that vacuum tubes have been used and studied for a much longer time than have transistors The latter are but recently developed and have considerable margin for change and improvement"

Annotations

PRINTING DISPUTE

SINCE work was provisionally resumed in the London printing-houses seven weeks ago, we have produced abnormally large issues of our journal so as to make up for some of its deficiencies in February and March But some obligations to subscribers and contributors inevitably remain unfulfilled, and, now that a settlement of the printing dispute has been announced, the Proprietors have decided to extend subscriptions to THE LANCET for four weeks beyond the present date of expiry To readers who obtain the journal through a bookseller or newsagent, and who were supplied with our token copies in February and March no charge will be made for the four issues of July

ANÆSTHESIA IN OBSTETRICS

THE benefits of new drugs and techniques in general anæsthesia are only slowly being brought into obstetric practice There can be few set operating lists in obstetrics and anæsthesia may be needed at any hour of the day or night Consequently the duty of giving the anæsthetic often falls to a junior and inexperienced resident But obstetric anæsthesia is seldom a simple matter, the patient may be unprepared and seriously ill, and there is usually a second life to consider Anæsthesia now holds an unenviably high place among the causes of maternal mortality,[5] and it therefore seems likely that a proportion of maternal morbidity and fœtal complications can also be attributed to it Yet modern methods, properly applied, have much to offer, not only by making conditions safer for operative obstetrics but by conferring advantages which, though less easily measured, can be found in such factors as a higher than normal maternal oxygen concentration and relaxation of skeletal muscle without uterine or fœtal depression

On another page Dr Coleman and Dr Day describe the use of a cuffed endotracheal tube in obstetric anæs-therapy The average myeloid erythroid ratio was 3 9/1 in both the treated and untreated groups Therefore in this series there is no evidence of stimulation of the bone-marrow by these dosages of radiation to the spine

Plasmacytosis

The normal level of plasma cells in the bone marrow was discussed by Hayhoe and Smith (1951), who reviewed the findings of several other workers and concluded that 2% or more was above the normal maximum

In the 10 patients with an increase in plasma cells (2 0–3 8%) there seemed to be no relationship between the plasmacytosis and a history of previous irradiation Of the 18 patients who had not been treated with X rays 6 showed plasmacytosis Of the 6 patients who had received previous irradiation 4 showed plasmacytosis Although, when investigated the E S R was raised in patients showing plasmacytosis, the converse was not true

The plasmacytosis may be explained by some relationship between ankylosing spondylitis and rheumatoid arthritis Hayhoe and Smith (1951) reported 10 consecutive cases of rheumatoid arthritis showing an increase in bone-marrow plasma cells, which was usually associated with an increase in the plasma-globulin fraction The plasma-proteins, however, were not studied in the present patients with ankylosing spondylitis

Eosinophilia

The normal level of eosinophils (both mature and precursor forms) in the bone-marrow was considered to be up to 7 5% (Whitby and Britton 1953)

Among the 4 patients with eosinophilia (8 4–14 6%) in the present series 1 had received X-ray therapy, but the 3 others had not 2 of the patients with eosinophilia showed also plasmacytosis (1 had received X-ray therapy but the other had not)

Eosinophilia occurs in many diseases where there is a body reaction to foreign protein In all 4 patients with eosinophilia the E S R was raised

Summary

28 bone-marrow examinations are reported from patients with ankylosing spondylitis

The only significant abnormalities in the bone-marrow were plasmacytosis in 10 patients and eosinophilia in 4

These findings could not be correlated with previous X ray treatment

We are grateful to Prof J S Mitchell for advice and permission to publish

ORAL STREPTOMYCIN IN BACILLARY DYSENTERY

GEORGE SANGSTER
M.D Aberd
ASSISTANT PHYSICIAN
CITY HOSPITAL FOR INFECTIOUS DISEASES, EDINBURGH

THE high prevalence of bacillary dysentery in the past fifteen years has apparently been uninfluenced by the introduction of chemotherapy and antibiotics, nevertheless the prevention of spread of dysentery may be aided by the successful treatment of acute cases and carriers

In recent years sulphonamides have produced fewer bacteriological cures in bacillary dysentery, this is generally held to be because resistant strains of shigellæ have appeared, and therefore the use of antibiotics must be considered seriously

Zintel et al (1945) showed that streptomycin administered orally produced a high concentration in the gut (particularly after four days treatment) and that absorption was negligible The earliest reports of its use in bacillary dysentery came from the United States, and good results were obtained by Hardy and Halbert (1948) in 37 cases of Flexner (Z) dysentery treated with 1 or 2 g daily for three days Ross et al (1949) gave a longer course for an average of 10 7 days to 34 cases with results which compared favourably with those in a control group treated with sulphadiazine In Shanghai, Chang and Su (1951) claimed a reduction in mortality from 14 to 4% using streptomycin. in their series of 110 cases they confirmed the rapid clinical response and the early disappearance of shigellæ from the stools, reported by the American workers

There are few reports from this country, and no large series has been published In a study of the sensitivity of *Shigella sonnei*, Forbes (1953) successfully treated 16 acute cases and 1 carrier with oral streptomycin, he gave 0 5 g *twice daily for two or three days with bacteriological* cure in all cases, although in 1 case the fæces proved bacteriologically positive on the sixth day after treatment 3 additional cases responded satisfactorily to streptomycin after sulphonamides and chloramphenicol had failed

More recently Abbott and Parry (1955), comparing the efficacy of tetracycline, phthalylsulphathiazole and oral streptomycin in Sonne dysentery, found that of 25 cases of all ages treated with streptomycin (0 5 g twice daily for three days) only 9 (36%) were cured by one course Similar results were obtained in the sulphonamide group of which 34% of 32 cases were cured by a seven-day course, but a high degree of success (96% of 27 cases cured) was achieved with tetracycline, again with a seven-day course

Previous Series

Of 200 consecutive patients (94% of whom were infected by *Sh sonnei*) treated in the City Hospital, Edinburgh, in 1948–49 with a seven-day course of succinylsulphathiazole or phthalylsulphathiazole or a combination of both drugs, all the 30 patients over 6 years old were cured by one course of treatment But of the 170 patients who were under 6 years old, only 106 (62%) were cleared by one course, 38 (22%) were cleared after two courses, and a further 8 (5%) after three courses, the remaining 18 (11%) were ultimately given streptomycin orally (1 g daily for five days) with good results, after four to six unsuccessful courses with several sulphonamides

The satisfactory *response in these 18 cases (they* were essentially convalescent carriers, having had positive stools for twenty nine to eighty-three days before streptomycin was started) *prompted me to use streptomycin* in acute cases In 13 such cases, the clinical response was entirely satisfactory, symptoms subsided in two to three days and all fæces were bacteriologically negative for periods ranging from thirty to fifty-eight days after the end of the five day course I therefore decided to adopt this form of treatment routinely for children, and later I extended it to patients of all ages

Present Series

The series comprises 1474 cases of proved bacillary dysentery treated with a five-day course of streptomycin at the City Hospital, Edinburgh, during the five years between November, 1949, and October, 1954 Cases of "clinical" dysentery and non-specific enterocolitis similarly treated are not included Most of the patients (1177) had *Sh sonnei* infections and the remainder (297) had *Sh flexneri* (type Z or X) infections, there were 1421 acute cases and 53 symptomless carriers The patients' ages ranged from 5 days to 79 years, most of them were under 10 years of age with chest pain there may be more in an advanced stage of the disease than there are among those who first have other symptoms." Taylor and Waterhouse[10] found that only 3% of 332 in whom the illness began with pain had a pneumonectomy, compared with 9% of those in whom the illness began with a cough and 13% of those in whom it began with hæmoptysis. Neumann et al., however, noted little difference in the proportion who underwent resection between patients under 40 and patients of all ages.

There is probably a greater danger in young people that the correct diagnosis will be missed, for in them lung cancer may not be so readily suspected. As we seem to be in the early stages of what has been termed a "pandemic" of lung cancer[11] this disease might well be put higher on the list for differential diagnosis even in those under 40.

SEMI-RETIREMENT

LAST week the National Insurance Advisory Committee recommended that the earnings rules for retirement pensions should be relaxed.[12] By their terms of reference they could suggest no radical changes, but their report has strengthened public interest in the principles on which our pension scheme is based. The committee recommended, and Parliament has now agreed, that retirement pensioners shall in future be allowed to earn 50*s* instead of 40*s* a week without loss of pension, and that pensioners earning over 50*s* a week shall have sixpence deducted from their pension for each shilling earned between 50*s* and 70*s* a week. This means that a pensioner can earn up to £5 a week before his pension is extinguished.

Probably these changes are as far as we can go without jettisoning the principle of pension on retirement rather than at a fixed age. Whether the principle is worth retaining is another matter. When unemployment was a national bugbear it was sensible to encourage elderly people to retire early and to give them some modest help to do so. But overemployment not underemployment is now our trouble, and today it might be equally sensible to encourage old people to remain at work as long as possible. Furthermore the proportion of old people in our population will rise steadily in the coming years. The help that they could give us will accordingly become more substantial, and, if need be, make it worth altering or adapting industrial traditions. In his reservation to the Phillips Committee's report Prof. A. K. Cairncross recast the problem. "Men of 65–70 (he said) should be free to choose not whether to retire but how much to retire." It is doubtful whether our present system of pensions gives them this freedom.

In defence of the principle of retirement and its bulwark the limitations of earnings, it is usually argued that employers would use the pensioner to cut wages, and that we cannot afford to pay full pensions irrespective of earnings. The advisory committee note that the abolition of the earnings rule would cost £76 million straight away. In his recent review of the subject Mr. Alan Peacock[13] was not greatly moved by either of these objections. The trade unions, he felt, might be relied on to defend the wage front. The Government Actuary on the other hand he thought might be overanxious. Had he not left out of account what the pensioners would bring to the Treasury by their effect on production and by their own increased expenditure? But Mr. Peacock agreed that the subject was difficult, for we are discussing the pensions problems "without any supporting inquiry into the economic resources of the aged."

Our nescience does not cover only the economic problems of the aged but extends to the intricacies of their pattern of employment. Here Mr. F. Le Gros Clark, with the backing of the Nuffield Foundation, is offering us a series of detailed reports on the kind of jobs that the elderly find for themselves. In his latest report[14] he has continued his inquiries among the employment exchanges and has discovered that many of the jobs found for the elderly are those that "have survived with us from the largely unmechanised world of the past." Perhaps this is a complementary problem to automation and one which in its way may prove as important.

POLIOMYELITIS FLOCCULATION REACTION

SPECIFIC flocculation reactions take place when a bacterial or viral antigen and its specific antibody are brought together under suitable conditions; macroscopically visible aggregates or clumps, appearing in antigen-antibody mixtures but not in controls, indicate a positive result. The term "flocculation" covers two phenomena: agglutination reactions, in which suspensions of large particles, such as bacteria, are clumped by specific antibody; and precipitin reactions in which very small particle antigens (often referred to loosely as soluble antigens) are precipitated by their specific antibody. Basically the reaction is the same in both cases. The term flocculation is sometimes used to cover them both, and also to describe the clumping of particles intermediate in size between bacteria and small particle antigens—for example, viruses. Antigens which flocculate with their specific sera usually fix complement under appropriate conditions, and flocculation and complement fixation have been useful techniques in investigating the antigenic properties of viruses and the serological responses of men and animals to infection. Flocculation reactions generally require the use of more concentrated and purified antigens than do complement-fixation tests, and for that reason the latter have been more often applied in virological investigations.

Recently Belyavin[15] showed that a specific flocculation reaction between influenza virus and antibody could be used for serological investigation of these viruses. Prof. Wilson Smith and his colleagues have followed this by applying the flocculation reaction to the poliomyelitis viruses, and on p. 710 they show very clearly that specific flocculation occurred when purified type 1 and type 3 poliomyelitis virus antigens were mixed with specific rabbit antisera. There is also preliminary evidence to suggest that specific flocculation may take place with sera of children convalescent from poliomyelitis. The test is likely to be useful in investigating the antigenic structure of the poliomyelitis viruses. On the other hand it is less likely that without substantial modifications the test will be much used in the routine laboratory diagnosis of poliomyelitis. This is because relatively large amounts of an antigen which has been previously concentrated 38.5 or 77 times are required, and it may be that complement fixation would be a more economical test to apply to this material. If not, however, the possibilities of a micro test seem well worth exploring. It would also be important to devise some method of inactivating the virus, if the test is to be used as a routine laboratory procedure.

THE next session of the General Medical Council will open on Tuesday, May 29, at 2.15 P.M., when Sir DAVID CAMPBELL, the president, will deliver an address. The Medical Disciplinary Committee will meet on Wednesday, May 30, at 2 P.M.

steady increase to approximately 25% in 1951–53, and by 1954 the proportion had risen to almost a third This increase was not responsible for the poorer results obtained latterly (table II) because, although the over all Flexner figures are slightly lower in the under-6 age-group, the chances of success after one course are more or less equal—i e , 4 out of 5 cases were cured, irrespective of the type of organism

TABLE IV—RESULTS OF TREATMENT WITH ORAL STREPTOMYCIN OR PHTHALYLSULPHACETAMIDE

Drug	No of cases	No of cases cured with			*Sh sonnei*	*Sh flexneri*
		1 course	2 courses	2 courses plus oxytetracycline		
Streptomycin	102	87	10	5	71	31
Phthalylsulphacetamide	102	53	28	21	73	29
Total	204	140	38	26	144	60

A Further Sulphonamide Trial

During 1953, sulphonamide was given a further trial Half the patients were given phthalylsulphacetamide ('Enterocid') in the recommended dosage for five days and half were given streptomycin (1 or 2 g according to age) for four days , all cases were treated as far as possible under similar conditions and the test of cure described above was employed Both groups were comparable as regards age and duration of symptoms The results are summarised in table IV

Better results might have been obtained with phthalylsulphacetamide if a longer course (seven days are recommended) and perhaps larger doses had been given Nevertheless it was clear that the sulphonamide results, which were similar to those obtained in 1948–49, did not compare favourably with those of the oral streptomycin group Although the four-day course of streptomycin was as effective as the five day course at that time, it was decided to continue with the latter to provide suitable comparison through the years

Discussion

The choice of dosage and duration of the course of oral streptomycin was influenced to a large extent by the experimental work of Zintel et al (1945), who suggested that 1 g of oral streptomycin daily would give a maximum concentration of streptomycin in the lower bowel of a healthy subject after four days Because the calculation of an optimum dose for each case was impossible owing to many variable and unpredictable factors and the absence of accurate fæcal estimations of streptomycin, I felt that a fixed amount, perhaps excessive in some cases, would be best, particularly as the effect of the streptomycin was almost entirely local Although the tests of cure in this series are not ideal, they were satisfactory in practice , in most cases which were still infected, confirmation was obtained from the first three clearance specimens

Forbes (1953) showed that, in vitro, streptomycin kills *Sh sonnei* in lower concentrations than aureomycin, chloramphenicol, or oxytetracycline, but that *Sh sonnei* acquires resistance to streptomycin earlier than to the others While this suggests that a short course of treatment is advisable, the speed of bacteriological cure is likely to be affected by the extent of the disease in the lower bowel and the accessibility of the organisms The five day course was considered sufficiently short to reduce the risk of resistance to negligible proportions , but, as a further precaution, if no sensitivity test had been done the course was repeated once only when indicated If the second course was unsuccessful another antibiotic (chloramphenicol or oxytetracycline) was given—with satisfactory results in all but a few cases Although the proportion of cases in the under-6 age group requiring more than one course of streptomycin increased from 11 to 20% during the survey, at least 95% of cases were cured by two courses throughout the five-year period (table II) This high degree of success attained by a second course does not suggest that the shigellæ soon acquire resistance but possibly in time this disadvantage will become more apparent

There were no toxic effects of the treatment , a few infants had a mild dermatitis in the napkin area, which may have been produced or aggravated by the streptomycin, but this subsided within a few days after the treatment was stopped

The results were equally satisfactory in acute cases irrespective of the duration of illness before treatment, and in carriers Moreover, the rapid control of symptoms (particularly diarrhœa) probably to some extent reduced the risks of auto-infection and cross infection A further benefit, of considerable importance to the patient as well as to the hospital, was the reduction of the patient's stay in hospital , this led to a considerable saving of time and beds Initially the cost of streptomycin treatment was relatively high, but this was offset by the advantages of a quicker turnover, and, with ever falling prices, streptomycin can now be used economically on a wide scale

It seems that streptomycin, administered orally, is useful and safe in the treatment of bacillary dysentery, and is to be preferred to sulphonamide That bacterial resistance will in time render it less effective is distinctly possible, but at present there is no strong indication for the routine use of newer antibiotics, some of which may have certain disadvantages

Summary

In 1949–54, 1474 cases of proved bacillary dysentery were treated with a five day course of streptomycin Although the percentage of first-time cures fell over the five years, the results in 1954 were still better than those previously obtained with sulphonamides , at least 80% of cases were cured by one course and 95% by two courses

A small trial (204 cases) in which phthalylsulphacetamide and streptomycin were compared showed that streptomycin was more effective and that the sulphonamide results were similar to those obtained before streptomycin was used

Oral streptomycin proved highly effective in clearing carriers who had been treated unsuccessfully with sulphonamide, as well as in acute cases

It is safe, reliable, and economical, but in time drug resistance may render it less effective

I am indebted to Dr A Joe, medical superintendent of the City Hospital, Edinburgh, for his support in this investigation The initial supply of 'Enterocid' was kindly provided by British Schering Ltd

symptoms necessitated their recall. Where abnormalities had been found, a large film was taken and the patient was given a clinical examination and sputum tests (or, in the absence of sputum, a laryngeal swab). When other lesions were suspected—e.g., bronchiectasis or amœbic abscesses (which were frequent)—physical examination and special laboratory tests followed and the patient usually went to the tuberculosis hospital for bronchoscopy or bronchography. But, with all these diagnostic facilities, some cases remained undiagnosed. They were those with cavitation resembling tuberculosis but with negative cultures and equivocal histoplasmin and other skin tests. Though sputa were repeatedly examined for parasites and fungi, our facilities for and knowledge of, special methods were quite often insufficient for any firm diagnosis.

Sputum tests were based on the standard staining technique, followed by cultures to exclude acid-fast saprophytes. Owing to the shortage of incubator space only those positive sputa could be cultured which did not tally with the radiological appearances. Before the termination of the project amendments to such technical shortcomings had already been approved.

As a routine cultures were set up in two bottles, one containing Lowenstein-Jensen and the other Medlar-Sesano medium, which were prepared in the project's own laboratory. The processing of cultures was hindered by shortages of reagents unobtainable in Thailand, by electricity cuts which affected the running of the incubators, and above all by contamination with moulds, which during the rainy season abounded everywhere—in books, in shoes, in clothes, and (not surprisingly) in the laboratories too. Repeated revision, and strict observation, of sterility rules on which expert advice was sent from the Serum Institute in Copenhagen, reduced the contamination-rate to 3% at the time of the team's departure and after another year's experience it had come down to 1%.

The laboratory also undertook tests of sensitivity to streptomycin and drugs, blood grouping, and clinical blood examinations (for which a small room with separate entrance was set aside). It did routine examinations of excreta, especially for intestinal parasites and their ova.

Prevention

In the domain of prevention the public health nurses held the key position. As soon as the diagnosis of tuberculosis was made or suspected, the doctor referred the patient to them.

The general plan was directed towards:

(1) Prevention of primary infection.

(2) Prevention of breakdown of lesions seemingly healed.

PREVENTION OF PRIMARY INFECTION

Elimination of Source of Infection

As it was impossible to admit every patient to hospital the first subject of instruction was the collection and *disposal of sputum* and contaminated material. The standard practice was to use as sputum containers the cigarette tins so abundant in Thailand. They had to be placed on a charcoal fire until the contents turned black, and the nurses spent much time in explaining their correct use, recommending a no-touch technique in which the tins were handled with tongs. When it was discovered that little children—numerous in nearly every dwelling—played with the tins and upset their content patients were told to put them out of reach; but, since in hot countries people squat on floor mats, such counsel proved more theoretical than practical. A new plan was therefore adopted whereby rolls of toilet paper were used as handkerchiefs and were immediately slipped into paper bags, made from newspaper, which could easily be fixed on a chair or at the bedside and could be burned daily. This became also the routine method at the tuberculosis hospital, where a paper bag was attached to each bed—which was quite handy for the very sick and instructive to students. The nurses then advised on how to cleanse contaminated linen—by soaking it in soapy water before washing—and on how to make full use of the sunlight for the sterilisation of blankets, pillows, and the like. In tests made by W.H.O. bacteriologists in India the sun killed tubercle bacilli, in a layer 2 mm. deep, in two hours, and its sterilising action has earned it the title of "the most effective minister of health in the East."

The next important step was to impress on the patient the need for *segregation*, particularly at night. This was the most difficult preventive measure to put into practice. In Bangkok two types of dwelling were in use by the needy:

(1) Huts made of bamboo and atap palm, or of wooden planks built on stilts. Though sometimes there was space under the house, this was often flooded (the rainy season lasts five to six months) and full of refuse.

(2) Small one-storey houses in rows in narrow lanes with no space outside in which sleeping benches could be put up.

The average size of a room accommodating about 6 persons was 4–5 square metres. Ventilation was fairly good on the whole, and the rooms were generally kept clean; but sanitation was extremely poor, with primitive means of disposing of fæces and waste. Lighting was by kerosene lamps which were a fire hazard. Furniture was at a minimum, the chief item being a mosquito net under which five or six people slept on grass mats on the floor.

Desperate though this situation was in most of the dwellings, there were some more spacious habitations which even had a yard or some little extra ground where a separate bench could be erected. This had to be

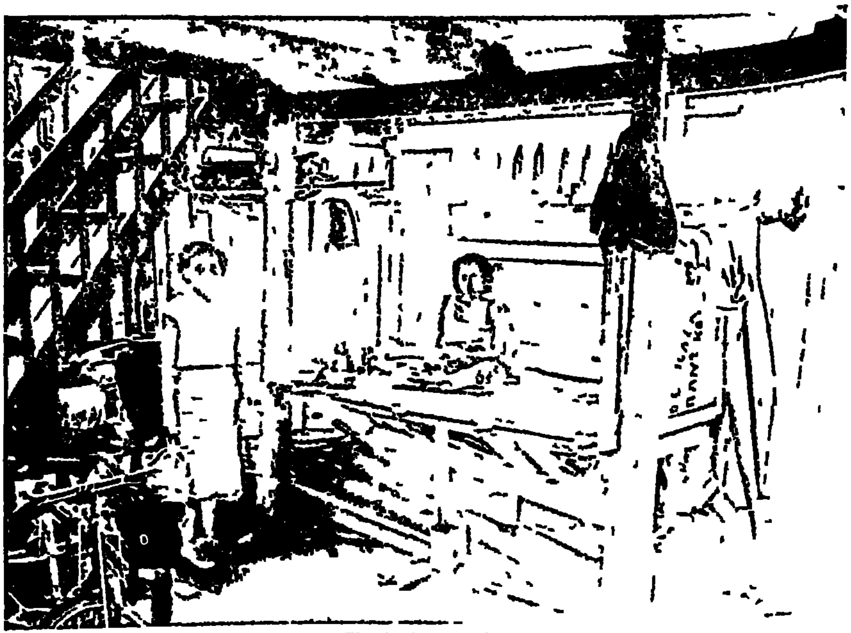

Fig. 1—Segregation.

Where some grounds or a yard were available, tuberculous patients were advised to use simple inexpensive sleeping benches made of wood from crates or remnants of wooden boxes. A mat was laid on the floor of the bench and a mosquito net affixed. The health visitor is seen on the left.

are presented in fig 2 Normal serum produces a dark lavender colour, whereas the serum in hepatolenticular degeneration produces a pale flesh colour The difference is so striking as to be recognised at a glance

Comment

The sequence of development of the characteristic biochemical abnormalities of hepatolenticular degeneration is unknown In several reported series the lowered serum copper-oxidase activity presented the most consistent and striking abnormality (Bearn and Kunkel 1952, Cumings et al 1955, Markowitz et al 1955) The lowered serum-copper-oxidase activity may be the most firmly established biochemical defect by reason of having been present longest—i e, the initial manifestation of hepatolenticular degeneration Reasoning on different grounds has led others (Bearn 1953, Scheinberg and Gitlin 1952) to suggest that deficient synthesis of cæruloplasmin (copper-oxidase) might be the primary defect If this hypothesis is correct, the use of this simple and inexpensive colorimetric technique in screening patients with obscure disease of basal ganglia or of the liver should detect those with incipient hepatolenticular degeneration far earlier than is at present practicable

It is not known whether the enzyme deficiency of the serum is always present from birth or has a gradual or abrupt onset before the development of clinical manifestations If the latter, a normal or near-normal oxidase activity could conceivably be found in someone who subsequently develops hepatolenticular degeneration Therefore, until evidence has accumulated on this point, it would be unwise to discount the possibility of early hepatolenticular degeneration on the basis of a single normal determination

Summary

A simple colorimetric technique is described for the estimation of serum-paraphenylene-diamine oxidase

Application of this test in cases of obscure liver or brain dysfunction may lead to the detection of early hepatolenticular degeneration and to earlier and more effective therapy

PHYSICIAN, ST JAMES HOSPITAL LONDON

C C BOOTH
M B St And, M R C P
MEDICAL REGISTRAR AND TUTOR

D L MOLLIN
B Sc, M B Wales
LECTURER IN PATHOLOGY (HÆMATOLOGY)

POSTGRADUATE MEDICAL SCHOOL OF LONDON

It is now recognised that there is a deficiency of vitamin B_{12} in addisonian pernicious anæmia (Berk et al 1948) A similar deficiency may develop in patients who have undergone gastric operations (*Lancet* 1955) or who have intestinal anastomoses, strictures, or blind loops (Mollin and Ross 1954) It has also been described in about a third of the patients with a megaloblastic anæmia associated with "idiopathic steatorrhœa" (Mollin and Ross 1954)

Vitamin-B_{12} deficiency due to an inadequate intake of the vitamin is much rarer, at least in temperate zones Megaloblastic anæmia and neurological lesions responding to treatment with vitamin B_{12} have occasionally been observed in people who take a strictly vegetarian diet, from which all animal protein, including dairy produce, has been excluded (A G Badenoch 1952, J Badenoch 1954), in such persons low serum concentrations of vitamin B_{12} have been recorded (Mollin and Ross 1954, Wokes et al 1955)

This paper records details of a patient who was not a true vegetarian, but who had a megaloblastic anæmia associated with B_{12} deficiency which was due to inadequate intake of vitamin B_{12} in the diet

Methods

Hæmatological methods were those described by Dacie (1950)

Serum vitamin B_{12} assays were made with *Euglena gracilis* var *bacillaris* using the method described by Ross (1952)

Gastric biopsies were carried out using the tube designed by Wood et al (1949)

Fat balances were carried out over a continuous nine day period The patient was given a diet containing 50 g of fat daily After four days on this diet all stools were collected for five days and the fat content estimated

Absorption of vitamin B_{12} was estimated by determining the excretion of radioactivity in the fæces after the oral administration of a test dose of radioactive B_{12} labelled with cobalt 58 Details of the method employed have already been given (Bradley et al 1954, Baker and Mollin 1955)

Case-report

An old age pensioner aged 77 was admitted to hospital on Nov 6, 1954, complaining of weakness and fatigue of three months duration and of increasing swelling of her legs for one month

History

In 1919 she had a gastro enterostomy for relief of a duodenal ulcer After the operation pain persisted and she severely restricted her diet Since 1943 she had existed on a diet of bread and margarine tea and potatoes She had taken no meat or fish, and her only available source of animal protein was the small amount of milk with which she flavoured her tea For a year before her admission to hospital she had taken orange juice daily For many years she had taken about 2 oz of Glauber s salt daily and she passed about five or six watery motions a day For ten years she had suffered from distressing prolapse of the rectum There was no history of anæmia in her family

Examination

She was a thin poorly nourished woman (height 5 ft 3 in weight 6 st 1 lb) and she was too weak to stand She was obviously anæmic The skin was sallow but not icteric There was no finger clubbing, koilonychia, or purpura Her tongue was pale but there was no atrophy or glossitis There was moderate pitting œdema of the feet Pulse regular, 72 per min Blood pressure 100/70 mm Hg Jugular venous pressure not raised No cardiac enlargement Soft apical systolic murmur Respiratory system normal Old healed operation scar on the abdomen Liver and spleen not palpable Cranial nerves normal No weakness or wasting Tendon reflexes present and equal Plantar responses flexor No sensory impairment

Investigations

Blood picture —Red cells 1,200,000 per c mm Hæmoglobin 5 4 g per 100 ml Packed cell volume 18% Reticulocytes 2% Mean corpuscular volume 150 cμ Mean corpuscular hæmoglobin concentration 30% Leucocytes 5000 per c mm Stained blood-smears showed macrocytosis and marked anisocytosis and poikilocytosis Sternal marrow biopsy showed moderately severe megaloblastic change Serum-B_{12} concentration was 75 μμg per ml (normal range 100–900 μμg per ml)

Barium meal —The œsophagus was normal The barium passed immediately through the stoma of the gastro enterostomy into the jejunum and also, less rapidly, through the pyloric end of the stomach into the duodenum and afferent limb The afferent limb was short and peristalsis was satisfactory The stoma functioned well and no ulcer was seen

Gastric secretion —Histamine fast achlorhydria was shown on two occasions

Gastric biopsy —Three fragments were obtained at biopsy Dr I Doniach reported 'There was moderate reduction in the thickness of the gastric mucosa Though in some parts specialised cells were partly replaced by mucous neck cells, our doing this on a large scale, but the need for going on with such work was impressed upon our Thai colleagues

A B C G campaign—Parallel with these activities of the public-health nurse a B C G campaign was started at the outset of the project The first object was to test and vaccinate Bangkok school children, but machinery had to be created for an eventual all-Thailand campaign of teaching and propaganda, and medical, nursing, and lay personnel had to be trained in the technique of testing reading, and vaccinating In eighteen months all Bangkok school children were covered by this programme, though a proportion of children of school age who did not attend school were not at first included Over 90% of all the negative reactors accepted vaccination At the age of 15, 73% boys and 63% girls were already tuberculin-positive

After the establishment of our B C G team, in which lay vaccinators played an essential part, a mass campaign was launched, but when it had been in progress for over four months it was handed over to a newly appointed W H O senior medical officer At the time of transfer more than 233,500 children had been tested and nearly 84,000 vaccinated—i e, 90% of the negative reactors By June, 1955, this separate W H O /UNICEF unit had tested nearly 4 million persons, and vaccinated over $1^1/_2$ million They found a much higher proportion of positive reactors in Bangkok than in the smaller towns and the countryside

A small survey on the rate of conversion was undertaken by our project in September, 1952, on nearly 4500 children in the age group 5–18, who had been vaccinated six to ten months previously 81% were found to have converted to positive

Preventive activities had to be carried into the patient's home, but the large number of nurses needed for such a purpose were not to be had in fact, to recruit more nurses was a perpetual struggle Home visiting was a trying and tedious job Transport difficulties were enormous—buses overcrowded, *samlors* (the popular tricycle) dangerous, and the project's facilities wholly inadequate Most of the patients' dwellings were far away from the main roads, often they could be reached only by a quarter of an hour's walk over cat planks (fig 3) or through muddy lanes In the constantly hot and humid climate all this was bound to tire out any home visitor Then there were "the baffling masses of houses and shacks with no sequence or complete lack of numbering, forming a bewildering topography," to quote the W H O public health nurse's report Often the patient could be found only by mouth to mouth inquiry —which took a lot of time Yet, to make preventive work effective, repeated visiting was essential Nurses had to make friends with the patient and his family, who themselves were encouraged to spread the gospel of prevention Much help was given to our project by the W H O /UNICEF maternal and child health project, whose nurses looked after the tuberculous in their area

A monthly radiological survey of all pregnant women was made at the maternal and child health centre by our project's mobile X ray unit The tuberculous were given priority for admission to hospital

PREVENTING THE BREAKDOWN OF LESIONS SEEMINGLY HEALED

Whereas prevention of primary infection was chiefly the concern of the public health nurse and of the B C G team, prevention of breakdown in those already infected was that of the social services Among the patients attending the chest clinic, undernourishment and worry seemed to be the main causes of such breakdown Houses were overcrowded, and vitality and resistance were low, public assistance was still rudimentary, and there were no monetary grants or food supplements Because of financial stringency, our project was not granted an international social worker, but the medical social work expert of the maternal and child health project was able to tap a number of resources for tuberculous patients, thus affording material help to some of them This showed that funds were to be had if one looked for them, and led to fuller recognition of social needs

Treatment

Treatment was taught and practised under two main headings

1 Simple procedures for reducing cough and sputum and "cooling down" an active lesion, and for managing tuberculous meningitis

2 Major procedures for closing cavities and eradicating the tuberculous disease

The simple procedures have already been described they constituted the standard treatment for the out patients of the chest clinic The major procedures were confined to the Nonburi Tuberculosis Hospital, situated in the country, about 22 km from the clinic

By a happy chance an American thoracic surgeon Dr John Wilson,* had been assigned to the Washington University group attached to F O A, to teach in the Thai medical schools, and after several ward rounds with our team, he offered his help in alleviating some of the distressing complications

Within two weeks a blood transfusion service was organised with medically selected inmates of the Bangkok prisons enlisted as donors (No risks were taken with rubber tubings and bottles, new sets being employed every time, with the result that a few minor but no major reactions were recorded in our eighteen months' work) Similar arrangements were made for electrolyte and fluid replacement Instruments anæsthesia apparatus, and other requisites were borrowed from various hospitals and ordered abroad by the government The anæsthetist of Dr Wilson's team, and his operating room supervisor, gave the necessary assistance one of the two resident medical officers was trained in anæsthesia and one nurse in operating room technique

A number of empyemas were relieved by drainage, and within a few weeks the first thoracotomy was performed—on a very ill woman who had had pain and discomfort from a plombage plasty with pingpong balls placed in her chest two years previously This first major operation proved more difficult than was expected, but the result

---

* Now head of the surgical department in the medical school of the American University of Beirut

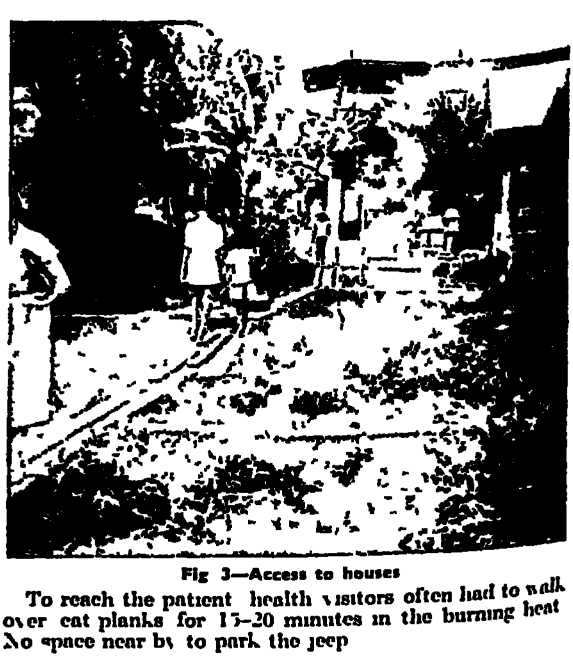

Fig 3—Access to houses

To reach the patient health visitors often had to walk over cat planks for 15–20 minutes in the burning heat No space near by to park the jeep pathological investigation. In this consecutive series there has been no mortality or complications, even though many of the patients were unfit for adrenalectomy. No evidence of any damage to the optic chiasma has been found. (In 2 cases with choroidal metastases vision has improved.) 1 patient, who has been in remission for a year, has a unilateral sixth-nerve palsy, the cause of which is as yet undetermined. There has not been a case of basal meningitis, or of cerebrospinal rhinorrhœa following this procedure.

Further careful assessment and follow-up of these cases is essential before any firm conclusion is reached, but apparently this method of accurate implantation and controlled dosage may prove a safe additional palliative measure in advanced carcinoma of the breast.

New Inventions

AN ARTICULATING ENTEROTOME

Since Paul first modestly described his method of colectomy with the formation of a spur in 1895, his operation has continued to be used by surgeons all over the world. In a bad risk case, or where, for a technical reason, colectomy with end-to-end anastomosis is dangerous, Paul's operation still offers a safe method of resection and approximation of the colon.

When restoration of continuity becomes necessary, various devices have been used. Some surgeons prefer formal end-to-end anastomosis, others use various techniques for destroying the spur. The success of the second stage of this operation depends on efficient destruction of the spur between the two loops, and numerous methods and instruments have been used to achieve this. Paul applied a pair of long dressing-forceps, tying the handles together with rubber tubing. Many kinds of enterotome have been used, including one devised by Dupuytren. All the instruments used for this purpose suffer from some defect, and it is difficult to devise one which is satisfactory in all respects. There are certain important points, however, which must be fulfilled if an enterotome is to be efficient.

(1) The blades must be sufficiently long to crush the whole spur, even in a patient with a fat abdominal wall.

(2) The blades should move parallel to one another and not, for example, as the blades of a pair of scissors, otherwise there is a tendency for the instrument to slip off, and for the deepest part of the spur to be uncrushed.

(3) The tips of the blades should meet first, though not so soon that they bite through the spur at the first tightening.

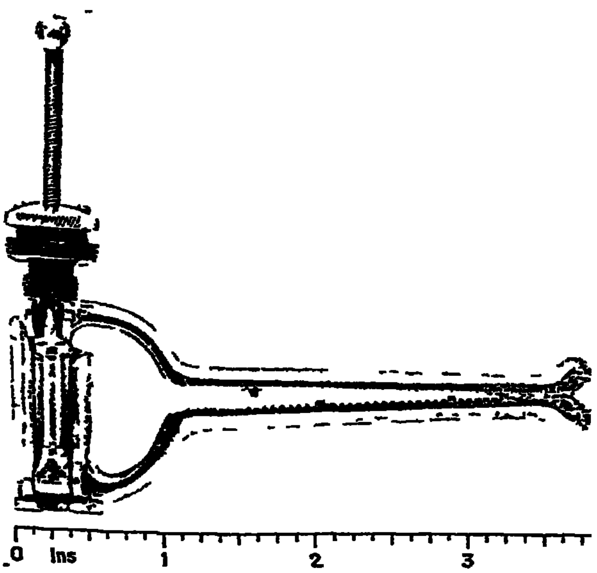

Fig 1

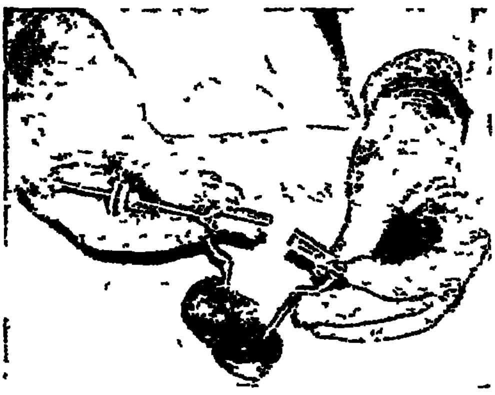

Fig 2

(4) There should be studs on the blades to stop them from slipping.

(5) The enterotome, when locked into place, should lie flush and snug against the abdominal wall.

(6) There must be a screw device which will approximate the blades and later separate them.

(7) If possible, the blades should be detachable one from the other, so that, when the colostomy lies awkwardly, each blade can be separately introduced into each loop of the colostomy and articulated when in position. They may then be screwed up tight.

I have used the instrument described below for five years and can honestly say that, on the whole, it has given satisfaction and does crush the spur right down to its base.

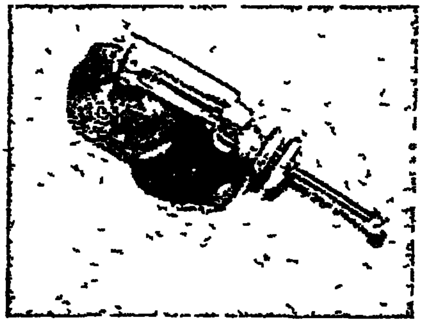

Fig 3

The instrument (fig 1) which is of stainless steel, consists of two serrated blades which "dovetail" like the blades of a pair of artery forceps. The female blade carries a hinged arm, which, when the male blade is slid into position, locks the blades together by means of a collar and knurled nut. The nut both approximates and (most important) separates the blades; it is double because a single nut tends to become unscrewed. The over-all length of the instrument is 4 inches, the blades are 3 inches long and $^1/_4$ inch wide. Each blade is studded to prevent slipping. The instrument is bowed outwards above each blade because, if the spur is crushed in its whole extent, there is a danger that the instrument may fall inside the bowel. Each blade is separately introduced (fig 2), and, when in position, as may be ascertained by passing a finger down alongside the blade, the two blades are locked together and screwed home. When the instrument is articulated and in place (fig 3) it lies fairly flat against the abdominal wall and does not protrude, and so does not tend to move as the patient moves. It is important to lock the blades fairly tightly on the first occasion, and they should be tightened at intervals until they can be tightened no further.

The Lloyd-Davies-Bond enterotome incorporates most of the features set out above, but the instrument described here can be disarticulated to enable the blades to be applied separately and then reassembled easily.

I wish to thank Mr Paul Dawson-Edwards for advice, Mr W Hanke, of Brierley Hill, Staffs, who made the prototype, Mr W E Smith, instrument mechanic of the Queen Elizabeth Hospital Birmingham, who modified it, and Messrs A L Hawkins & Co Ltd, 15, New Cavendish Street, London, W 1, who have made the existing instrument for me.

work between Thai, American, and W H O medical personnel

During two terms medical students, in groups of ten, were instructed on how to suspect, diagnose, and prevent tuberculosis, and on first-aid management of the emergencies of the chest It proved more difficult to impart modern knowledge on diagnosis and prevention to undergraduates than to postgraduates, since their professors still put their emphasis on physical signs, hardly considering prophylaxis at all They were also encouraged to spread the gospel of prevention among their own folk and to put it into practice by each taking an interest in three or four tuberculous families Unfortunately, the departure of the international team did not allow this important scheme to be pursued

Whereas most of the above responsibilities were carried by the team-leader, a large teaching programme was also covered by the W H O public health nurse Besides instructing the four to six nurses of her own office individually, she gave courses to student nurses of various hospitals, public-health supervisors of rural areas, municipal nurses, midwives, and sanitarians—with practical demonstrations at the clinic and during home visits The reading of 70 mm films was demonstrated to small groups of doctors by the W H O epidemiologist, who also organised a mass-radiographic survey, supervised the technique of B C G vaccination, helped to build up the B C G campaign, and evaluated the figures with his counterparts The statistician trained two young lay persons, with degrees in mathematics, in comprehensive charting and the principles of medical statistics

On the whole it proved rather difficult to impart theory to technical personnel For example, the local radiographers had not had schooling of a standard enabling them to comprehend elementary physics, and one had to be content with their technical skill and satisfactory photography

Results of Teaching and Training

Diagnosis —When we left, a medical staff of nine were skilled in the diagnosis of tuberculosis and other common chest conditions in so far as the potentialities of the laboratory allowed Four doctors were conversant with the interpretation of 70 mm films within the normal range of over reading and under-reading The bacteriological study of tuberculosis was in the competent hands of the bacteriologist in-charge and two reliable technicians, and several technicians were in training The routine examinations of sputa, taking laryngeal swabs, the preparation of media, the setting up of cultures, sensitivity tests, and (above all) the precautions for sterile handling of material, were under control Three technicians had become accomplished in radiographic technique and two doctors in bronchography and bronchoscopy

Prevention —All the medical staff and the small staff of nurses understood the meaning of prevention and the importance to that end, of combating cough and sputum

Treatment —More than ten doctors had full knowledge of routine procedures and of the diagnosis and management of the emergencies of the chest There was one fully trained surgeon with more than 60 major interventions, resections, and 'plasties (without any fatality) to his credit and a sufficient number of doctors to assist, including one acquainted with the principles of anaesthesia No major transfusion accidents had occurred and no postoperative abnormalities of posture On the medical side the following case histories may illustrate the standard of responsibility attained

(1) A tuberculous diabetic with ketonuria, tension pneumothorax and empyema left the hospital with his diabetes controlled his chest cleared of pus the lung almost re expanded and the residual pleural space obliterated by thoracoplasty His sputum had been freed from tuber bacilli and his weight increased by 7 kg

(2) A woman of 21, seven months pregnant and seriou ill with typical miliary tuberculosis, had complained of seve headache The cerebrospinal fluid was characteristic of tuber culous meningitis With standard treatment her sympto and her fever had long subsided, the cerebrospinal fluid h become normal, save for the number of cells (56 per c mm when she was delivered of a healthy child The baby wa immediately segregated and after four weeks was vaccinat with B C G Treatment of the mother continued until h condition was stabilised

In the past, the presence of a tuberculous lesion wa almost always regarded as an indication for endin pregnancy But when our Thai colleagues under tood that all children are born free of tuberculosis, and scheme for treating the mothers and segregating and vaccinating the newborn was put into operation, th previous policy was abandoned

Retrospect

Was this particular project in Thailand justified?

All three participants invested considerable fund UNICEF generously furnished a laboratory with modern apparatus, sent a mobile radiographic unit, a radioscope, and all the requisites for a mass B C G campaign (including a number of vehicles), and ensured a continuous flow of chemicals, radiographic film material, tuberculin, B C G vaccine, and a number of other items, even after our departure W H O provided the experts and repeatedly sent special advisers, also supplying some apparatus, instruments, and literature The Thai Government fulfilled all its obligations with regard to buildings with reasonable speed it completed a two storey laboratory, an extension to the chest clinic allowing separation of infectious and non infectiou patients, a new hospital block, and a nurses' home, and it commenced and planned a number of other buildings It procured high-quality radiodiagnostic apparatus and modern instruments for thoracic surgery The hospital wards were reconstructed and newly furnished The government also provided all the counterparts to the international personnel, and an additional staff of drivers, motor mechanics, technicians, doctors, and nurses

Among the Thai personnel there were able and talented doctors, nurses, and technicians, but salaries were generally low As a government division, the tuberculo i project could not create a precedent in this matter and the head of the tuberculosis division could certainly not be blamed for the failure to satisfy various social need of his staff But technicians—especially radiographer trained by W H O personnel—were in constant demand elsewhere, and many public health nurses and doctors had to do private practice to earn their living, particularly since most of them had large families This also accounted for a great deal of absenteeism of the nurse

Nevertheless a tuberculosis control project, with diagnostic, preventive, and curative sections, was established, and staff were trained sufficiently for each section to carry on the work indeed the facilities for diagnosi and prevention would have been the envy of many a Western tuberculosis service Moreover, interest in the fight against tuberculosis has been aroused, both in the population and in the medical profession This is reflected in the fact that, a year after the W H O team's departure attendance at the chest clinic had doubled, the chief of the tuberculosis division had been given a teaching appointment for tuberculosis at one of the medical schools, and frequent demonstrations on clinical and pathological chest material were being held by the Thai Medical Association Modern standards of diagnosis prevention, and treatment of tuberculosis are for the first time systematically attained in the country The project's laboratory has become the expert centre for

GLAXO LABORATORIES LTD, GREENFORD, MIDDLESEX BYRon 3434

J B Field and **De Witt Stetten** described studies on insulin resistance during diabetic acidosis They showed that the quantity of insulin required to save the patient was proportional to the concentration of a serum factor which inhibited the uptake of glucose by the isolated rat diaphragm Further observations on one case located this factor in the α globulin fraction, no adrenal or pituitary effect could be detected

K J Isselbacker, E A Anderson, and **H M Kalokar** demonstrated unequivocally that the essential lesion in galactosæmia is an absence of a specific intracellular enzyme, phosphogalactose transferase

R H Rosenman, S O Byers, and **M Friedman** reported work on anti kidney serum induced nephrosis in rats By preventing the external loss of urine they showed that hyperlipæmia and hypercholesterolæmia did not occur and, if urine loss was permitted, could be reversed by the continuous intravenous infusion of plasma albumin **R M Kark** supported this by reporting 3 patients in whom the intravenous administration of salt free albumin reduced the serum cholesterol and cholinesterase activity

At the meeting of the Association of American Physicians, **C A Janeway** described an arthritic syndrome in children with agammaglobulinæmia It was a polyarthritis, always involving and usually beginning in the knees, and going on to involve the middle sized joints Characterised by intermittent hydrarthrosis, it eventually led to chronic changes in the joints The syndrome was independent of any treatment received, and its ætiology was obscure

An interesting account was given by **I L Bennett** and his associates of an outbreak of pseudomembranous enterocolitis in chinchillas This was due to pathogenic staphylococci and promptly disappeared when aureomycin, which had been added as a growth promoting factor, was removed from the diet A section was shown from the bowel of a patient who died in 1893 from pseudomembranous enterocolitis Appropriately stained, groups of staphylococci and superficial necrosis, very similar to the chinchilla's lesions, were clearly visible

Data on a stilbene like compound (amphenone) were presented by **R Hertz** and his colleagues This substance was shown effectively to suppress adrenocortical activity, but was unfortunately a powerful narcotic Prolonged search has so far failed to reveal non-toxic analogues

W B Shelley and others described studies on the neurophysiological basis for itching They showed first that only certain spots on the skin can feel an itch They were about 1 mm in diameter, 1–2 mm apart, and localised in the dermis Further work showed that the sensation was caused by proteolytic enzymes, of which a number of examples, including trypsin, were given No structural changes were observed

J E Howard reported preliminary studies on a functional test for the detection of hypertension produced by one kidney The method used was to collect urine separately from each ureter, and to estimate its sodium content The concentration of sodium was lower in the urine from the affected kidney

Federation of Experimental Biologists

The Federation includes physiologists, biological chemists, pharmacologists, experimental pathologists, nutrition experts, and immunologists, and in the joint proceedings, also at Atlantic City last month, we were offered 2071 papers read in full (and a number of others by title only) in five days

The most significant papers were probably those recording synthesis of a virus by W M Stanley, H L Fraenkel Conrat, and R Williams,[1] of the California Institute of Technology They took two strains of the tobacco mosaic virus (a and b), broke them into two parts, one protein and one nucleic acid (a_1 and a_2, b_1 and b_2), and then reconstituted them as two new viruses (a_1 and b_2, b_1 and a_2) They went on to show that not only were the reconstituted viruses infective, whereas the fragments were not, but that many of the important qualities of the virus resided in the helical shaped nucleic acid

A series of joint sessions was devoted to atheroma J P Strong and his associates showed that subintimal fatty deposits were always present in human aortas by the age of 3 years, and that the rate of infiltration is greatest between 5 and 15 years T M Lin and his colleagues reported studies on 9 healthy subjects fed on standard diets supplemented by varying amounts of pure cholesterol They showed that, although absorption increased as the total dietary cholesterol increased, the blood-levels remained remarkably constant D W Petersons and his co-workers, however, showed that blood-cholesterol levels could be reduced by adding about 5 7 g of soy sterols daily to a normal diet, this could be concealed in butter, was quite tasteless, and produced falls, of 11% or greater in blood cholesterol J W Hahn and M A Nyman found that whole blood was capable of considerable synthesis of free cholesterol, phosphatides, and fatty acids when passed through a glass cannula, and that this effect was enhanced if a living aorta was substituted for the glass tube, implying some lipid synthesis by the aorta itself

Two papers with immediate clinical application are mentioned from the excellent series on blood clotting A J Quick reported a case of a woman of 22 with a history of mild bleeding since childhood and two severe postpartum hæmorrhages After the second, he found a normal platelet and prothrombin level, but clotting was indefinitely prolonged, and the thrombin time was 43 seconds (normal 3 seconds) He attributed these findings to hyperheparinæmia, and he was able to produce a similar picture by injecting papain into the rabbit D P Jackson and his colleagues reported severe abnormalities of blood coagulation after hæmolytic transfusion reactions in 2 patients In both there were hypofibrinogenæmia, hypoprothrombinæmia, and thrombocytopænia and in neither was there evidence of fibrinolysis One patient had reduced ac globulin activity and plasma thromboplastic component, and a circulating anticoagulant in low titre The picture could be reproduced in experimental animals by injecting thromboplastic substances, and it was suggested that the disorder followed the release of such a substance from lysed red cells

In the section on kidney diseases R C Mellors and L G Ortega gave a fascinating account of the localisation of γ-globulins in the kidney in human nephritis Using an ingenious technique they were able to show that, whereas there is no γ globulin in sections of normal kidneys, or in a variety of other conditions (e g, infarct, pyelonephritis), γ globulin is present in acute hæmorrhagic glomerulonephritis and in chronic membranous glomerulonephritis, but it is confined to the glomerulus

These and many other papers are summarised in the *Federation Proceedings*

Personal Papers

EYE-WITNESS AMONG THE EUGENISTS

The other day I turned up an early manuscript of my own, written some sixty years ago, which describes the first public meeting of the then embryo Eugenics Society As a medical student I enjoyed the meeting so much I lost no time in writing this detailed report For reasons that it may be evident it has not hitherto been published

A short time ago many learned people met together in London to discuss the "Improvement of the Race," or as the subject has recently been christened, the Science of Eugenics A casual enquirer after truth had inadvertently come into possession of a ticket of admission and was fortunate enough to be present at the meeting

The audience was composed of both sexes, and, in view of the subject under discussion, presented an interesting spectacle Healthy young men and women, parents of the next generation, in whose hands lay the immediate steps towards improvement, and to whom the meeting might be of some practical import, were singularly lacking In their place were the old and decrepit the halt the blind and the lame Hardly a

Burns and Scalds*

When the kettle is upset the first decision must be Do I treat this myself or do I call the doctor ? When the doctor arrives his first decision must be Do I treat this myself or do I send it to hospital ? In reaching these decisions the two most obvious guides are the extent of the injury and the degree of shock but a third factor which must be considered as soon as possible is the depth to which the damage has penetrated for failure to recognise that a burn or scald is a deep one is still responsible for long periods of disability Our correspondent whose letter appears on p 750 tells how his wife who is 80 years old, scalded her foot with half a pint of boiling water The exposure treatment was advised and for weeks the patient was confined to bed, suffering severe pain Treatment of burns by exposure [1] comes as a surprise to the many people who have been taught that the first thing to do for these injuries is to exclude the air immediately [2], and naturally our correspondent is doubtful of the value of a method which brought so much distress Probably in this case the scald went deeper than was at first appreciated Scalds, even when only a small area is involved, may be very deep and boiling water may entirely destroy the thin skin of an octogenarian, whereas in the same circumstances it would leave intact the deeper skin cells in the forearm of the baker After very similar accidents therefore, the baker s lesion may heal in fourteen days, and the old lady s may take months

From the days of Dupuytren doctors have recognised the significance of depth as well as the extent of damage, and his ' six degrees have been the accepted classification for over a hundred years

> " nous avons divise les brûlures en six degres ainsi caracterises 1° erytheme ou phlogose superficielle de la peau, sans formation de phlyctenes, 2° inflammation cutanee avec decollement de l epiderme et developpement de vesicules remplies de serosite 3° destruction d une partie de l epaisseur du corps papillaire, 4° desorganisation de la totalite du derme jusqu'au tissu cellulaire sous-cutane. 5° reduction en escarres de toutes les parties superficielles et des muscles jusqu'a une distance plus ou moins considerable des os 6° carbonisation de la totalite de l epaisseur de la partie brûlee " [3]

With advances in skin-grafting techniques, however, plastic surgeons have concentrated on distinguishing between two or perhaps three, groups—undoubted skin survival, undoubted full-thickness loss, and cases in which a period of waiting is necessary before it is certain that epithelium will grow over the area again The first 2 of Dupuytren s degrees belong to the first group, the last 3 to the second, and the 3rd degree (which provides most of the cases in hospitals and casualty departments) includes the ' uncertain " burns In the early stages the surface appearance of a burn is only a rough guide to its depth, for it can give no sure indication that the dermis has or has not, survived [4] Tests for circulation may be deceptive for pooling of blood in dead capillaries may produce reversible blanching on pressure when, nevertheless, coagulation necrosis will result in deep sloughing a week or two later Loss of sensitivity to pinprick in areas such as the trunk legs arms and backs of the hands (but not the face, scalp palms or soles), may indicate full-thickness destruction This is perhaps the only physical sign of much help in the first few days Sometimes a firm decision cannot be made until the eschar is beginning to separate, and this may not be until after the second or third week Electric burns in which the current has passed through the wound are particularly difficult to assess and their depth is very often underestimated

When the family doctor has decided to treat a burn or a scald at home, what can we regard as the modern treatment and what advantages can it claim over such simple remedies as ointments or picric acid ? The exposure method produces a hard coagulum within two or three days, but, as our correspondent makes plain, the pain may be considerable Local applications relieve the stinging and they have the added advantage of making it apparent that something is being done Moreover, doubt has recently been cast on the superiority of the exposure method by Lowbury et al [5] who showed that although the dry surface of the coagulum remains sterile the bacterial flora on its under side, where it is hoped that skin regeneration is taking place may be varied and prolific The probability is that when skin damage is only superficial, there is little to choose between the healing-times with any form of treatment If the initial estimate of depth is accurate, therefore those cases suitable for treatment at home should respond to any method and there seems to be no objection to the application of a soothing dressing and to the exclusion of air Before the development of blisters an anti-histamine ointment may minimise the reaction If blisters have appeared, the ' cleavage dressing ' [6] of two apposed pieces of tulle gras provides relief and allows a reassessment in four or five days without disturbing the surface of the burn itself The outer layer of tulle gras can be peeled off carrying with it caked gauze wool, and bandage This leaves the inner layer attached to the burn, which while still virtually undisturbed is painlessly displayed for inspection All burns should be gently cleaned with a detergent, and dried, before the first dressing is applied Opinion is divided on the use of antibiotic powders as a local application In giving their views on the management of burns,[7] the Association of Plastic Surgeons held and arteriovenous nipping are not dissimilar from those *found in man, the crocodile would seem to be an ideal* experimental animal, though minor technicalities remain to be overcome

Meanwhile, at Barthomary's Hospital, clinical studies continue Two active principles have now been isolated, yenwupongine and venwupongeine, both of which, when suspended in vitriol and administered by surreptitious injection, produce perivascular cellular infiltration, necrosis, and refusal to submit to further treatment This phenomenon, known as Ducane's triple response, is thought to originate at some place in the craniotarsal axis, though some would dispute this hypothesis Other toxic side-effects may include leucocytosis, leucopenia, frequency, oliguria, depression, euphoria, wasting, obesity, diarrhœa, and constipation Clearly, the theoretical justification for the exhibition of yenwupongine and yenwupongeine has not yet been fully elucidated, nor are these measures free from hazard But the physician has acquired a remarkable chemical tool which, if used judiciously, may lead to a better understanding of a common disease of today

* * *

Parents and psychiatrists may be concerned because cowboys and Indians have lost their appeal Robin Hood is a back number, and all the current heroes are intrepid explorers of outer space and distant planets But for one anæsthetist it is a blessing The six-year-old spaceman never objects to the bathing-cap which is affixed preoperatively It is so like a space-helmet that it might have come straight from Dan Dare himself The anæsthetic face-piece holds no terrors for the modern nipper, for all the best space-men apparently breathe oxygen from a similar device Induction is carried out smoothly with appropriate asides—"Air-lock closed," "No two motor ready"—so that the roaring in the ears which heralds impending unconsciousness follows quite naturally The rocket motors are on (Somehow they never did seem to swallow that yarn about the workmen outside in the street)

This simple deception can be easily enhanced by the glittering paraphernalia on the average Boyle's machine A laryngoscope makes a very fair space-gun, an ethyl-chloride spray a convincing death-ray And Magill's forceps are just the job for removing meteorites from Martians' hooves

Lit-tle Gee-Pee is very hap-py be-cause his poorly pat-ients are all get-ting bet-ter on Sachets of Servo-assisted Senna, the new Wonder Drug "Ha-ha!" he laughs!

Lit-tle Gee-Pee reads all about Sachets of Servo-assisted Senna in the Fairy Tale Picture Books which the kind Uncles at the manu-fact-urers' of-fices send him ever-y morn-ing

But here comes Teacher! She is cross with Gee-Pee for pre-scribing Servo-assisted Senna in-stead of Bis-2 4 6 8 diethyleeni-meeni-amino-p'-benzaldehideho-dehyde of senna (90% u p) *N F* (Wasn't that a long word, Teeny-tinies? Be sure you get it right, or Jolly Uncle Jack at the Pric-ing Bur-eau will have to make you write out your pre-scrip-tions all over again!)

"You are a *naughty* boy, Gee-Pee!" scolds Teacher "Instead of play-ing golf this after-noon with the other lit-tle girls and boys, you will stay in after Surg-ery and write out fif-ty times, in your best hand-writing, 'The Standing Joint Committee on the Classification of Proprietary Preparations and the Joint Committee on Prescribing Know Best'"

"Boo-hoo!" cries poor Gee-Pee "*I will tell my* Psy-chiatrist about you!" But his lit-tle friends Sam-my Statist-ician and Rupert the Rep do lots of hard sums, and—what do you think! They find that Sachets of Servo assisted Senna cost ever so many less pennies than Bis- 2 4 6 8 diethyletcetc *of senna* (90% u p) *N F*!

Off they scam-per to tell Teacher, and now they are *all* staying in after Sur-gery *ever-y day this week* to write out one hun-dred times, in BLOCK CAPITALS, "I must not teach my Grand-mother to suck expensive medicaments" And there will be lots of pen-nies de-duct-ed from their quarter ly cheques!

(An-other teeny-tiny tale soon)

Letters to the Editor

SMOKING

SIR,—The Minister of Health's cautious pronounceme on the association of smoking with cancer and th tobacco firms' pontifical edict belittling the importa evidence to date[1] are disappointing but understandabl for the health service, for which the Minister is responsibl derives a substantial part of its financial nourishme from taxation on tobacco, while the tobacco compani have naturally to consider their employees and shar holders In the face of such powerful vested intere it is not easy for our profession to convince the publ of the dangers of smoking it is even more difficult f those of us who are already enslaved by the habit

The recent increase in tobacco duty suggests that th Government already have a guilty conscience, but wh did they not give a moral lead by increasing the ta on cigarettes only, for these represent the princip threat to health? They should have announced the intention of introducing legislation to prohibit the s of tobacco to persons under 18 and so educate the publ to adopt, as with alcohol, a responsible attitude towar its enjoyment At least they could have determined t warn National Servicemen, for whom they have a speci responsibility, of the insidious and costly nature of th cigarette habit

The tobacco companies' "smoke screen," to which yo referred in your annotation last week, is cleverly worded they speak of "a *possible* relationship" between lun cancer and smoking when the profession has accepte the association for some time, and "a *suggestion* tha smoking *may* be a *contributory* cause" (italics all mine They note that only a small proportion of smokers con tract this disease, which occurs also in non smoker What are they waiting for? Until every smoker contract cancer and until all atmospheric pollution has bee banished? Not everyone falls victim to smallpox o poliomyelitis in an epidemic, but this fact does not dete the State and the profession from doing their best t save as many lives as possible But even more perniciou is the firms' claim that smoking is a boon to million and that its benefits, both physiological and psychologica and as yet ill defined, might well be the subject o scientific research Such subtle propaganda as they hav put forth, directing the public's attention away fro the lethal facts, is calculated to stimulate the hardene but recently scared habitue to once more reach out fo a packet of his favourite blend of the drug and to incit others, including susceptible teenagers, to investigat for themselves these alleged benefits It would b salutary for the boards of certain tobacco companies wh actively encourage the growth of the cigarette habit t see the final stage of the grim tragedy, as do we, all to often, on the necropsy slab Their generosity in providin money for research was unquestionably activated b humanitarian interest, but at the same time it inspire the public's trust in their policy and judgment, the have therefore assumed a grave moral responsibility

As a profession it is our clear duty to be outspoke and broadcast the important truths which have *alread* been established We can vehemently discourage smokin in adolescence and warn against its habit-forming tend encies We can begin now to speak of "tobacc *bronchitis,*" "*smoker's cancer of the lung,*" "smoker cancer in the liver (or in the brain)," so that the publi will the more quickly learn to associate cause with effect Finally, we who enjoy a smoke can ourselves se an example by keeping the habit under control

W H McMENEMEY

London

---

[1] *Times* May 8 1956

criteria for physical signs a tumour was also found in a considerable proportion of well babies of this age (25 of 115 babies under two weeks old). A barium meal was given to 62 of the babies, and hurry seemed more common than delay in emptying of the stomach. Post-mortem examination of the pylorus in 138 newborn or stillborn babies did not reveal any muscular hypertrophy corresponding to this frequent clinical finding of a palpable tumour. CRAIG's important conclusion was that a palpable tumour in the first two weeks of life is not evidence of an organic change in the pylorus: it seems rather to indicate a dysfunction which can resolve rapidly. It is comforting, however, to note that these tumours, although similar to those of hypertrophic pyloric stenosis in rather older babies, were not usually identical. They were not so firm, well defined, or rapidly contractile, and they did not fit so aptly the classical description of the tumour of pyloric stenosis as resembling an olive suddenly appearing beneath the examining finger. It seems that attention to detail must be even stricter in assessing a palpable tumour in the newborn than in the slightly older baby suspected of having hypertrophic pyloric stenosis.

CRAIG discusses the condition of pylorospasm as an entity causing vomiting in the absence of organic pyloric hypertrophy. On the other hand THOMPSON and GAISFORD[13] believed it "exists more in the mind of the pædiatrician than in the abdomen of the child". WOOD and ASTLEY,[14] however, when they were studying a group of babies with vomiting of uncertain origin, considered that they had radiological confirmation of pylorospasm in some of their rather older "non-persistent vomiting babies". Clinically their cases bore some resemblance to those described by CRAIG. In a contrasting group, there were persistent vomiters, some of whom later showed evidence of gastro-œsophageal abnormalities. These conditions, such as œsophageal hiatus hernia, must also be borne in mind in the diagnosis of vomiting in these younger babies. Perhaps the term pylorospasm should be retained as a convenient label suggesting a reversible upset of function rather than as an exact diagnosis. CRAIG agrees with THOMSON's view[15] that such babies often empty their stomachs by repeated small vomits rather than by one copious vomit as in typical hypertrophic pyloric stenosis. The affected babies in CRAIG's series stopped vomiting with no more treatment than gastric lavage, but he mentions the possibility of giving antispasmodics. Some people may feel that this might confuse the issue and lead to difficulty and delay in diagnosis when there is in fact an organic cause.

CRAIG's investigation is modestly described as a pilot study showing that a palpable tumour is not evidence of organic hypertrophy of the pylorus in babies under two weeks of age. Further research along these lines should increase our knowledge of gastric function in the newborn. Moreover this knowledge may become of increasing practical importance in the examination of babies who are shown by such ætiological studies as those undertaken in Birmingham, to have a greatly increased risk of developing true hypertrophic pyloric stenosis.

The Medresco Hearing-aid

THE Medresco hearing-aid was introduced with the National Health Service in 1948 and it remains one of the very few appliances that can still be obtained entirely free of charge, on the recommendation of a consultant otologist. That it is one of the most widely appreciated amenities of the health service has long been apparent to those working in hearing-aid clinics. What is perhaps not quite so fully recognised is the type of case likely to benefit from the use of a hearing-aid. Deafness can be classified into three broad categories: conductive deafness, from deficiencies in the sound-conducting apparatus; perceptive or nerve deafness, from affections of the neural apparatus of hearing; and mixed deafness, by which is commonly understood a combination of conductive and perceptive deafness. Many causes of conductive deafness, such as otosclerosis and inflammations of the middle-ear cleft, can be treated by medical or surgical means with varying degrees of success. When these measures are unsuccessful or the patient declines them, nearly all patients with conductive deafness can derive very real benefit from the use of a hearing-aid. The problem of perceptive deafness is much more difficult and the results less happy; for perceptive deafness is essentially untreatable and the hearing obtained through an electrical aid is less satisfactory. But fortunately most deaf people fall into the conductive group; and even in nerve deafness modern developments in construction and design have produced hearing-aids that can bring relief to many who were previously thought to be beyond their help.

The requirements of an ideal aid are "high amplification, high fidelity, small size and weight, low power consumption and low cost. Not all of these qualities can be achieved in practice. Objectives of low cost and light weight are directly opposed to the objectives of high fidelity, high amplification and long battery life".[1] This is certainly true of valve aids, and all models of the medresco are at present valve aids. It is also partially true of the newer transistor aids now being manufactured, but these do in fact combine lightness of weight with high fidelity, high amplification and long battery life. But a transistor aid costs considerably more than a valve aid. With increasing experience in the development of the transistor aid, costs should fall.

Last year GEFFEN and TRACY[2] recorded an investigation into the distribution and use of medresco aids supplied by the Royal National Throat, Nose and Ear Hospital in London to residents of St. Pancras. 419 aids were issued between June 1948 and May 1953, the period covered by the survey. 330 of these patients were visited and interviewed by one of the borough's sanitary inspectors. The object of the questionary was to determine how much the aid was used and how valuable it was. 31% used their aid all the time, 57% used it only part of the time, and 12% had ceased to use it altogether. In other words 88% derived some benefit from the aid. In almost half the cases the aid had never caused any trouble, and in a further third very little trouble; in the remainder the instrument had failed frequently

[1] Fisch, L. *Med. ill.* 1954, 8, 302.
[2] Geffen, D., Tracy, S. M. *Med. Offr*, 1955, 93, 261.

In (*a*) and (*b*), which are likely to be of long standing particularly in mitral disease, thickening of the alveolar basement membrane prevents the easy access of interstitial fluid into the alveoli [10]

It is fundamentally important to interpret radiographic signs logically (hence radi ology) in terms of anatomical site, disordered physiology, and pathological processes This valuable radiographic sign, appreciated years ago by Kerley,[11] should be regarded as indicating œdema of the peripheral interlobular pulmonary septa and *not* necessarily as indicating pulmonary hypertension The anatomical site is the interlobular septa ; the disordered physiology is œdema ; and the pathogenesis is either pulmonary capillary hypertension, lymphatic obstruction, or, less commonly, increased permeability of capillary membrane or hypoproteinæmia, depending on the particular clinical associations

Now that the basic mechanisms responsible for these lines are better appreciated, we are no longer justified in naming them in purely visual (and verbose) terms (e g , " basal horizontal lines on chest radiographs ") or by eponymous reference This valuable radiological sign should be given an anatomical designation (e g , " peripheral or [basal] interlobular septal lines ") or should be described in pathological terms (e g , " lines of interstitial pulmonary œdema ") When described in such terms, their significance will become more widely appreciated they represent the only objective evidence of waterlogging of the pulmonary interstitial tissue and its lymphatics

St Thomas's Hospital
London S E 1

RONALD G GRAINGER

SIR,—We were most interested to read the paper by Dr Rossall and Mr Gunning The findings agree substantially with our own [12] As we stated, " when lines B were absent the pulmonary capillary pressures were usually well below 30 mm Hg When present the pressures were almost invariably above 30 mm Hg " We agree with Rossall and Gunning on ætiology also " It appears likely that when the pulmonary capillary pressure approaches plasma osmotic pressure, there is exudation of fluid with deficient reabsorption "

We, too, found at first some difficulty in seeing basal lines in patients with heavy breast shadows, but this was overcome by taking an additional postero-anterior chest film of the bases with the mammary tissue well elevated by the patient's own hands The film, however, is likely to be too dark for diagnostic purposes unless some reduction is made in exposure—usually of the order of 3 kV

Our present studies suggest that, although the raised pulmonary capillary pressure plays a major part in the production of basal horizontal lines in mitral valve disease, in the other conditions in which the lines occur there are other factors of greater importance

J H E CARMICHAEL
D G JULIAN

Liverpool

TREATMENT OF BURNS AND SCALDS

SIR,—Last November my wife who is 80, scalded her foot very badly, although it was the result of upsetting only half a pint of boiling water Her doctor said that no ointment or oil should be applied, and the foot must be exposed to the air, even to the extent of keeping it out of bed for two nights, in none too warm weather

For weeks my wife was confined to bed, with severe pain for which no soothing substance was applied Later on penicillin injections were given It is only within the past two or three weeks that she has been able to get about while the foot has been, and still is very painful There is a large scab of wrinkled flesh right across the toes, from the stretching of which, during walking, blood has appeared in two places

Can this be considered a successful example of the modern method for dealing with burns and scalds? In contrast, I would instance the case of a local baker who badly burned his arms He was treated in the old-fashioned way, by applying ointment and covering the arms Within a fortnight he was back at work

UNCONVINCED

CYSTIC PNEUMATOSIS

SIR,—Cystic pneumatosis, although comparatively uncommon, cannot be so rare as is imagined Since 1951 two cases have occurred in this hospital Both were detected during routine barium meals and were subsequently proved at operation

Most workers agree that this condition occurs in association with intestinal obstruction

Nitch [1] described 85 cases and stated that 50% of the cases were associated with gastric or duodenal ulcer and in 83% of these pyloric stenosis was present

Mathews [2] reported a case of enteric pneumatosis in which the pelvic colon was mainly affected, the cysts being submucous and subserous

Griffiths and Ellison Nash [3] report a case of gastric ulcer with associated ileal pneumatosis, the affected loop being under the diaphragm and in a suprahepatic position and leading to a diagnosis of peptic perforation

The commonest complications are pneumoperitoneum and intestinal obstruction, including intussusception Nitch is of the opinion that the cysts and the affected portion of the intestine are best left alone unless causing obstruction by pressure, adhesions, or projection into the lumen of the bowel The cysts disappear in the majority of cases after the cure of the coexisting lesion

Jones [4] described a case in which a chronic volvulus of the sigmoid colon was associated with cystic pneumatosis of the large gut However, I am unable to find a reported case in which chronic volvulus of the jejunum was the obstructing lesion

CASE 1 —A man, age 49, was admitted to this hospital on Dec 6, 1951, with a two year history of intermittent dragging pain on the left side of the abdomen, associated with attacks of diarrhœa and constipation Subsequent barium enema revealed no abnormality, but straight radiographs of the abdomen showed mild pneumoperitoneum and several fluid levels in moderately distended loops of small intestine in the left upper quadrant Barium meal and follow through showed partial obstruction of the upper small gut but no abnormality in the stomach and duodenum

Laparotomy on Dec 23 1951, revealed volvulus of the upper jejunum The mesenteric border of the affected jejunum contained multiple large diverticula ranging in diameter from $^{1}/_{2}$ to 2 in The terminal ileum was affected by cystic pneumatosis, the cysts being subserous and situated both on the mesenteric and the antemesenteric borders All were small (about $^{3}/_{8}$ to $^{3}/_{16}$ in in diameter) and sessile The volvulus was reduced and the affected jejunum resected continuity being restored by end to end anastomosis

Convalescence was marred by a burst abdomen, but the patient was finally discharged as an inpatient on Feb 5, 1952

CASE 2 — A woman age 60, was admitted to this hospital on April 6, 1954 with a two year history of vomiting and indigestion indicative of pyloric stenosis The patient was thin and had a vague, tender, small epigastric mass Radiographic examination on April 14, 1954, showed free gas under both halves of the diaphragm and evidence of a small pyloric ulcer with severe spasm

Laparotomy was undertaken on April 20, 1954 when a firm hypertrophied pylorus was found in association with cystic pneumatosis of the terminal ileum, involving two isolated lengths 6 in and 9 in long The cysts which were about thesia primarily to prevent the aspiration of gastric contents The essence of their technique is to induce anæsthesia with a mixture of cyclopropane nitrous oxide, and a high concentration of oxygen, and then to use the short acting muscle relaxant, succinylcholine chloride to produce favourable conditions for intubation When the tube is in the trachea and the cuff inflated, they maintain anæsthesia on a light plane with a similar mixture of gases, and once the succinylcholine has worn off relaxation is produced by intravenous gallamine triethiodide Respiration is assisted or controlled as necessary Many people will protest that this seems to be an unnecessarily complicated technique for obstetric practice and that it introduces the potential hazards of muscle paralysis while not entirely excluding those of aspiration until the cuffed tube is in position Yet in its essentials this is a method with which many anæsthetists are familiar in the operating-theatres of general hospitals, and which, in its ultimate results, has been shown to be of considerable value Moreover the use of an endotracheal tube not only eliminates the risks of aspiration but also ensures adequate oxygenation at all times and satisfactory conditions for operation with the minimum of depressant anæsthesia Paradoxically, should it be desirable or necessary to deepen anæsthesia, this can be done easily and quickly All in all the obstetrician is not called upon to hurry because of the anæsthesia

[10] Parker F Weiss S *Amer J Path* 1936 12 573
[11] Kerley P J *Brit med J* 1933 ii 594
[12] Carmichael J H E Julian D G Penrhyn Jones G Wren E M *Brit J Radiol* 1954 27 393

[1] Nitch, C A R *Brit J Surg* 1923, 11 714
[2] Mathews F J C *Brit med J* 1951 i, 851
[3] Griffiths J D Nash D F E *Ibid* 1955 ii, 1602
[4] Jones J D T *Brit J Surg* 1948, 36, 49

With such a method dangers are most likely at induction and during the period before intubation is complete During induction there is a risk of vomiting, but with the onset of paralysis this is superseded by that of passive reflux In considering the prevention of these complications, not all anæsthetists would agree with Coleman and Day's method of induction with cyclopropane and nitrous oxide, which is relatively slow, followed by inflation of the lungs before intubation and with the patient horizontal Quicker loss of consciousness can be achieved by a 50% mixture of cyclopropane and oxygen inhaled from a 6 litre bag[6], and a head-up tilt will help to prevent reflux from the œsophagus when the patient is paralysed With this technique the mother's oxygen saturation remains high enough for intubation to be performed without prior inflation of the lungs, but the tube must be passed without delay

The success and safety of these and similar types of anæsthesia depend upon two essentials—an experienced anæsthetist and adequate equipment Indeed the standard of labour-ward anæsthesia—whatever the technique—will be raised only when both are freely available Coleman and Day are at pains to emphasise this and they point to the need for an efficient suction apparatus and a labour-ward bed that can be quickly tilted

If these methods of anæsthesia become generally acceptable in hospital practice, what should be done in domiciliary work? There is little to recommend them for use in the home even in the hands of an anæsthetist of experience There is a problem here, especially for the teaching hospitals What are students to be taught about obstetric anæsthesia and how are they to be equipped to deal with an emergency in domiciliary practice?

BRAND-NEW SHAMBLES

ALLOCATIONS to hospitals for capital expenditure still lag behind real needs, and we should all like to believe that any money which the country spares for this purpose is prudently used A few months ago a new operating-theatre suite was opened at a hospital in the Home Counties The following were among the defects which came to light

In the *theatre* eleven floor blocks were loose, when stepped on, they went down at one end and up at the other Four of the encased radiators leaked and every day rags had to be placed here and there on the floor to absorb the water

In the *sterilising room* the steriliser itself leaked and some of its taps leaked and could not be used It had been so installed that it could not be serviced without complete disconnection The hood above it, to collect the steam came no farther forward than the front of the steriliser Accordingly steam condensed on the ceiling from which water fell impartially on the sterile and the non sterile Subsequently the paint on the ceilings of the sterilising room and the sluice room peeled off

The *swing-doors* warped and dropped catching against each other

Most of the faults might perhaps have been averted by closer supervision of the building work, and one or two by consulting accounts of the design of other operating-theatre suites—this, after all is not the first to have been erected in Britain A harassed staff has for the past month been working in the theatre which they had hopefully discarded, while the new theatre is being put in order We hope that their unhappy experience may, by example help to avert such happenings elsewhere

LUNG CANCER IN YOUNG PERSONS

IN England and Wales during 1954 308 persons under 40 years of age were certified dead from lung cancer[1] This was only a small proportion—less than 2%—of the total lung-cancer certifications, but the disease in young patients has some interesting features For instance, the ratio of men to women—3 to 1—is lower than in older people and the squamous type of cancer is much less common Neuman et al,[2] at the Mayo Clinic, have studied 51 patients under 40 and found only 4 (8%) with squamous tumours compared with 34% among patients of all ages at the same hospital[3] On the other hand there were 37% with adenocarcinomas (the type believed to be less commonly related to cigarette-smoking[4-6]) whereas there were only 13% in the whole group In the young the disease runs a more rapid course In one series only 31% of patients under 50 who were not treated surgically or by radiotherapy survived for a year compared with 46% of those over 70[7] Neuman et al state that the survival-rate after resection is "definitely lower" in young patients But their conclusions are based on only 13 resections, and Bignall and Moon[8] found that in 77 patients under 45 who survived operation the five-year-survival rate—45%—was in fact higher than that of patients aged 45–59, and the distribution of histological types among their young patients was much the same as that in older patients There seems to be insufficient evidence at present to conclude that in young people the outlook after resection is necessarily bad.

Anderson et al[9] found that chest or shoulder pain was the commonest presenting symptom in 30 young men, this symptom was recorded in almost three-quarters of them In most large series of patients of all ages cough is the commonest early complaint There is some indication that among those whose illness begins amounts of ordinary alcoholic drinks for about ten years They then turned to methylated spirit for economic reasons and at a time of "heightened loss of morale"[1] However, as Dr MacDougall remarks, methylated-spirit drinking is by no means the last stage of alcoholic excess On the average a further five years of excessive drinking followed before these addicts reached what they themselves regarded as their "lowest point"

Compared with the majority of our alcoholic patients, the methylated-spirit drinkers were slightly lower in occupational status, intelligence, and rates of recovery and improvement Thus most of them belonged to social class III and were of average or just above average intelligence (compared with a large proportion in social classes I and II and of superior intelligence among our alcoholics in general) Methylated spirit drinkers were also found among small recent samples of homeless excessive drinkers (3 out of 40)[2] and of alcoholics admitted to a London observation ward (4 out of 56)

Drinking of methylated spirit was held responsible for the condition of the offender in approximately 0 9–1 8% of "proved offences of drunkenness" in England and Wales over the past fifteen years[3]

Warlingham, Surrey M M GLATT

ARTIFICIAL RESPIRATION

SIR,—I am writing on behalf of the chief medical officers of the area gas boards

Artificial respiration should be carried out immediately and uninterruptedly on people who have been partly asphyxiated by drowning, gassing, or electrical shock It is well recognised that a delay of even a few seconds may be fatal Nevertheless it appears to be common practice to move patients undergoing artificial respiration into an ambulance and to attempt to carry out artificial respiration on the way to hospital

It is highly improbable that satisfactory artificial respiration can be carried out in a moving ambulance, and it therefore follows that a patient who needs artificial respiration should have it on the spot This must be well known to all doctors who have considered the matter, but the fact that such patients are still put into ambulances indicates that the ambulance attendants are not aware of the correct practice We therefore suggest that all doctors who have to do with the instruction of ambulance attendants should emphasise and re emphasise this point

CLOSED TRAUMATIC LESIONS OF THE AXILLARY AND BRACHIAL ARTERIES

SIR,—I read with interest the successful results of sympathectomy for occlusion of the axillary artery described by Professor Rob and Mr Standeven (May 5) The following case responded to intravenous procaine

A woman, aged 67, was referred by Dr Curtis Bain, with thrombosis of the right axillary artery of seven weeks' duration The right hand and forearm were cold and pale the pallor increasing on raising the arm and on immersion in hot water Movements were weak and inhibited by pain No pulsation was palpable in the right brachial, radial, and ulnar arteries A feeble pulse was felt at the apex of the axilla The pulses of the left arm and both legs were normal

Intravenous infusions of 1 g of procaine hydrochloride in one pint of physiological saline solution were given at a slow rate daily for four days in the outpatient department Thereafter, procainamide 0 75 g daily in three doses was taken by mouth for one week Improvement began at once and after the third infusion was maintained Four to five hours after the third infusion the patient felt a wave of warmth steal down her arm, and she saw the veins of her hand fill up Pain on movement was reduced to a dull ache On the sixth day the stellate ganglion was blocked The hand warmed still further within five minutes—an effect similar to that at the end of an infusion of procaine hydrochloride This effect lasted four to five hours Eight days after the beginning of treatment she spent all the morning sewing with her right hand and complained of only a slight ache The right hand was now only slightly paler and colder than the left It became red and comfortable on immersion in hot water Sympathectomy now seemed unnecessary Six months later the brachial and radial pulses had returned

The vasodilating properties of procaine hydrochloride are cumulative and independent of the speed of infusion Unpleasant side effects can be prevented by slow administration The procainamide may or may not have been beneficial

General Hospital, Harrogate JANE PEARCE

PERFORATED ACUTE AND CHRONIC PEPTIC ULCER

SIR,—We owe a considerable debt to Mr Hermon Taylor for proving, beyond all doubt, that a diagnosis of perforated peptic ulcer does not necessarily demand immediate operation

However, I am a little confused by the recent report by Mr Taylor and Mr Warren of their treatment of 200 cases of perforation (April 14) Part of the confusion may be due to their published data having been limited by considerations of space

1 What proof is there that all these 200 cases had a perforated ulcer? The authors do not pretend that clinical diagnosis is very reliable, and indeed they admit to 17 proven errors in 108 cases Is it possible that there were other, unrecognised, mistakes? May we know how many unoperated cases showed no radiological evidence of gas in the peritoneal cavity?

2 They remark "it seems clear that partial gastrectomy is the treatment of choice" for perforated chronic ulcers which do not respond to conservative treatment With the utmost respect, it is not clear to me How many emergency gastrectomies were, in fact, performed, and was the number large enough to justify such a dogmatic opinion, from so authoritative a source, on a matter of such far reaching importance?

Why is it better to stop the leak by an operation lasting an hour and a half on a patient in rather a delicate state of health, when it can be stopped quite easily by an operation lasting fifteen minutes? It beats me

South Mimms, Herts V J DOWNIE

MEPACRINE FOR PETIT MAL

SIR,—Arellano and Alejandro[1] described long continued benefit in cases of petit mal epilepsy from mepacrine in a dosage, for patients over 7 years of age, of 100 mg every six hours to a total of 1 3–3 3 g In the two following cases I gave 100 mg six-hourly for four days to a total of 1 6 g

CASE 1 —An imbecile boy, aged 7 years, had had severe petit mal despite many different drugs The best regimen was phenobarbitone gr $^1/_2$ thrice daily and dexamphetamine 5 mg twice daily, but even with this the average number of petit mal attacks observed was 300 a month To his normal routine was added a course of mepacrine Fits immediately ceased for two weeks, they then returned in their former intensity but slowly decreased over the next month to a level of 2–3 a day, and this level has been maintained for the past three months This boy has improved as a whole and can now take a greater part in the games of his friends and walk to the occupation centre (about 200 yards) without falling Before treatment with mepacrine he had had to be taken in a chair —

TUBERCULOSIS IN THAILAND

The Story of a Venture

A J BENATT
M D
FORMERLY W H O SENIOR MEDICAL OFFICER,
TUBERCULOSIS CONTROL PROJECT, THAILAND

IN many Eastern countries, though immunisation of large numbers of children with B C G may be feasible, there are grave difficulties in introducing other Western methods of controlling tuberculosis Is it, in fact, worth trying to introduce them until social and economic circumstances change? In particular is it worth establishing a "tuberculosis control project" like the one in which I worked in Thailand? Since the answer to these questions is important for people in the East, I shall describe what we tried to do and what we did

Unlike its neighbours Burma, Indo China, and Malaya, the kingdom of Thailand has never been under foreign rule Its population of nearly 20 million are Siamese and Chinese—the latter mostly immigrants Poverty is wide spread Bad housing, overcrowding, and malnutrition—particularly in the capital, Bangkok, a city of over a million—provide all the conditions favouring a rapid spread of infections, including tuberculosis Tuberculin testing of school-children showed in 1951–52 a positive Mantoux reaction in 70% at the age of 15, suggesting that children are much exposed to the disease A random-sampling radiographic survey in 1954 revealed a tuberculosis prevalence of at least 5% in the capital, and the figure was probably higher in the poorer quarters Tuberculous meningitis and miliary lesions were common

The General Plan

Confronted with tuberculosis in a country where modern measures of control have hardly been attempted, a W H O team-leader will think it his principal task to prevent the spread of the disease, especially to the young The first essentials, when a case is recognised, are to make the sputum free from tubercle bacilli, by the simplest means, and to safeguard possible contacts Compared with the control of infection the further treatment of patients is a secondary objective

But, however correct this may be in theory, it did not prove workable in practice In Thailand we found a small tuberculosis hospital, of 75 beds, in which patients had been kept for years with little hope of recovery or discharge—a picture of gloom This hospital, having lately come under the jurisdiction of the tuberculosis division of the government, was the main concern of the chief of that division, and he asked our help in alleviating some of its worst features Our activities in the hospital were evidently to be the acid test of the usefulness of the international team—a *hic Rhodus, hic salta* So, without neglecting preventive duties, we had to give a certain priority to amending as well as preventing therapeutic disasters, and it was not long before we found that, in point of fact, understanding of the importance of the social aspects of tuberculosis or other diseases could be imparted to the national staff more effectively if relief to the physically distressed could be demonstrated In the two medical schools of Thailand, preventive and social medicine were not part of the curriculum With its discussions on ward rounds and clinical conferences the tuberculosis hospital offered a golden opportunity to inculcate and encourage thinking in terms of prevention, social needs, and rehabilitation

The Team and Its Language

Since 1949 a tuberculosis service of the Thai health department had gradually developed, with a physician in charge who had had several years' training in the United States A chest clinic had been established with a small laboratory radiological apparatus, and a small nursing service Under an agreement with W H O, an international team was to be sent to Bangkok to set up a demonstration centre and to teach and train local staff The government had promised to provide for each international member a suitable counterpart, preferably with previous experience in his field, the counterpart to the team leader being the director of the tuberculosis division Parts of the project were to be equipped by UNICEF

The international personnel, who were sent to Thailand one by one during the latter part of 1951, consisted of a British trained laboratory technician, a British public-health nurse, a Dutch radiographer, a Chilean epidemiologist, an Indian statistician, and a British team leader—this last replacing, in June, 1952, a Swiss physician who had initiated the project Two British laboratory experts came for short periods to give advice, and a Danish laboratory technician to revise the sputum culture technique A Swedish technician assisted for a few months in improving the radiological technique

The language was to be English As only a few of the Thai team, of whom some had held fellowships abroad, knew much English, the language barrier was (and remained) a difficulty, especially with the technicians, who had seldom learnt English at school However, the Thais got to know English far more rapidly than the international team got to know Thai To have to acquire a difficult language imposes a serious additional strain on people tired by a day's work in great heat and humidity, and I would urge the need for teams, *before* they go abroad, to get acquainted with the fundamentals of the language of the country to which they are assigned The language barrier is also important in relation to clerical assistance In Thailand, anyone proficient in English could earn from commercial firms high salaries with which the government could not compete Thus the international staff had to spend on clerical work much time that should have been spent in other ways

The Central Chest Clinic

The chest clinic lay in the heart of a congested middle-class shopping area in the centre of Bangkok In 1952, a few months after the project began, there was a monthly attendance of 2800 of whom more than 500 were new patients Two years later, when the project ended, the corresponding figures were 3500 and 750 Of those attending for the first time half were found to have tuberculosis

More than three quarters of those who came to the clinic sought advice of their own accord, others were referred by the mass X-ray survey of the project, while a few were sent by their doctors or by other organisations About 40% lived far outside the Bangkok area, and, in hope of getting effective treatment, many had to make long journeys by boat and train, not infrequently taking two or three days, or even longer, to reach Bangkok

A new patient entered the chest clinic by a special entrance which was also used by sputum negative patients Entrances and waiting rooms were put at the two opposite ends of the building so as to minimise the mixing of the tuberculous and non tuberculous When the team left, an entirely separate small block only for contacts was under construction

Facilities for Diagnosis

Every patient seeking advice had a 70 mm film taken by a static mass radiography unit At the same time the tuberculin test with 5 units P P D was applied If he was very ill, a clinical examination followed immediately, but otherwise he was asked to return in three days for the results of the miniature X ray and for the reading of his tuberculin test Patients without radiographic abnormalities were then discharged, unless special tions owing to intolerance and 22 4% owing to inadequate response Some may have failed to respond because they were suffering from a megaloblastic anæmia of pregnancy, which does not appear to have been excluded by examination of the bone-marrow

PRODUCTION OF CODEINE

SIR,—The enzymatic dehydroxylation of phenols, which Mr L M Spalton (March 24) claims is non-existent, is not an uncommon reaction Burton [1] has shown that dopa melanin is formed by the elimination of water between phenolic hydroxy groups A large number of analogous reactions have been reported [2]

Winnipeg Canada

E P EVANS

CARRAGEEN

SIR,—In your issue of April 14 a Peripatetic Correspondent says that he often wonders what chondrus or carrageen is

Carrageen is familiar to most people in Ireland and often is consumed as a sweet there It is a small seaweed, which has curly, branching fronds It is harvested on the shore and is washed and then dried and bleached in the open

It may be purchased loose from sacks in grocers' shops in towns near where it is harvested and elsewhere in packets in which it may be inspected through a transparent window It is packed loosely and is very light for its bulk

Nowadays its commonest use is for making a sweet which is a cross between jelly and blancmange, with a delicate flavour It is soaked for some hours in water and then discarded, the decanted liquid being heated with milk, which may be coloured at will and which some misguided persons also flavour artificially The agar like gel extracted by soaking causes the milk when cooled to set The resulting dish is light and readily taken in large quantity Hence it has a place in the diet of invalids

Its other medical interest lies in the fact that from ancient times it has been thought to have a value in the treatment of cough, being so used by the public to some extent even now and being incorporated in some commercial cough remedies widely sold at present in Ireland I doubt if it has any effect on cough apart from its soothing of the throat, but who am I to say that another Fleming may not at some later time say otherwise ?

If your correspondent or others not familiar with this weed would like to try some, I should be happy to oblige

Uarán Mór

SEAGHAN UA CONCHUBHAIR

THE PATTERN OF GENERAL PRACTICE

SIR,—I should like to thank Dr Richards (May 5) for telling us something of his experience of general practice and its relationship to medical education Though he said little that was new he presented many of the important facts and feelings in a connected and convincing way

For those who work and teach in hospital this kind of communication is most helpful, and I hope that other family doctors in differing types of practice will be encouraged to follow Dr Richards's example All medical practice, including general practice, requires both general professional education and specialised training In planning this for the undergraduate and early graduate stages we need to know more precisely than we do at present what are the proper functions of a family doctor today This is essential if the doctor in training is to make serious contact at appropriate points with the attitudes and experiences of family practice

I hope myself that at the undergraduate stage this contact will be limited, that in the preregistration stage we shall one day find time for a substantial apprenticeship for all in general practice, and that during the years of established professional activity we shall step out beyond the occasional "round" and the afternoon "course" into more imaginative forms of contact between the general practitioner and the specialist

Newcastle upon Tyne

DONALD COURT

RESEARCH DEFENCE SOCIETY

DR W LANE-PETTER, hon secretary of the Research Defence Society (11, Chandos Street, London, W 1), writes

On more than one occasion recently there have been broadcast programmes on the subject of animal experiments in which doctors have taken part May we, through the courtesy of your columns, invite any doctors or scientists who may be asked to take part in future programmes of this kind to remember that the Research Defence Society exists to help them in just this sort of activity

DAPHNE AND THE GREENFINCHES

MR MAX PETTERSSON, PH D (Linnean Society, Burlington House, Piccadilly, London, W 1), writes

In the classical myth Daphne was persecuted by Apollo, while in contemporary gardens her namesake, *Daphne mezereum* L , is newly set upon by greenfinches (This daphne species is the small shrub covered with a profusion of pink and fragrant blossom about March) A pair of greenfinches will gouge out every single seed, in May or June, and before the fruit is mature—to feed themselves and their nestlings To study the origin and spread of this new habit, I should be glad to hear of cases where this does, or does not, happen and, if it does, about how many years ago the first despoliation took place Further details are given in *Nature* (April 14 1956, p 709)

Public Health

Contaminated Flour ?

AT Pontardawe, Glamorgan, over 100 people were affected in an outbreak thought to be due to contaminated flour The first to be taken ill were those who had had bread rolls in a canteen Later, cases became more general in the village The illness began one to three hours after eating the bread Those most severely affected had epileptiform fits, sometimes accompanied by violent muscular contractions and followed by unconsciousness for up to one hour In milder cases there was weakness, twitching, nausea, and confusion of thought Some people became aggressive They all recovered, but a number were injured when they fell Inquiries suggest that 3 sacks of flour out of a consignment of 100 were contaminated—perhaps by coming in contact with some toxic substance Samples are being analysed

Help for the Family

Kent County Council recently completed the first year of a family-help service to households where there was temporary difficulty in looking after the children in their mothers' absence The aims of the service were to avoid breaking up the family and to reduce the cost of taking the children into the care of the county council It was limited to families of 2 or more children, with an initial term of not more than three months, and a contribution was assessed on the parents' means

The helpers were recruited mainly from the council's domestic help service, and they either lived in or visited daily 1000 children in 302 families were helped in that way during the year, with an average of twenty four days per family The cost of £5400 was estimated to be less than half the expense of taking them into the council's care

94% of the cases were the result of confinements or treatment in hospitals and convalescent homes, and the remainder were due to deaths or desertions 126 further applications for the service were not granted, most of those families made their own arrangements, and only 12 children had to be taken into care by institutions or foster parents Although it was intended that help should be withdrawn when the mother returned home, it proved necessary to extend it in some cases until she was able to cope with her children's needs constructed in the simplest possible way with the least possible expense to the patients most of whom were living below subsistence level The wood of crates or boxes was used for the basic structure to which a mosquito net was affixed (fig 1)

---

[1] Burton H *Nature Lond* 1948 161 725

[2] Mason H S *Advanc Enzymol* 1955 16 121

Because segregation was so difficult, other ways of preventing the spread of infection had to be found The *combating of cough and sputum* became one of the project's main objectives One of the recognised means of diminishing cough is rest, but this rule was hard to observe in the hot and humid climate of Bangkok moreover, most of the people had to go out daily to earn their living, whatever their physical condition—the more so since there was no system of financial assistance for the sick Streptomycin, with the two cover drugs, is usually effective against cough and sputum, but in order to get it the patient had to go to the chest clinic at a sacrifice of time working hours, fares, or rest We were considering, therefore, whether we could recruit and organise a flying squad of nurses who would go out in jeeps to the various districts to give streptomycin injections But when the first results of a Medical Research Council trial on isoniazid and *p* aminosalicylate treatment by mouth were published[1] this plan was abandoned The M R C workers had found combined use of these two drugs almost as efficacious as the use of streptomycin plus one of them, and since administration of isoniazid and P A S is a relatively simple matter, we hoped that the introduction of this combination might prove to be the *turning-point in the control of tuberculosis* in countries *en cours de développement*

Between January, 1954, and May, 1954, a total of 550 patients were treated by this method at the Bangkok chest clinic, and *at least* half of the patients receiving the two drugs for two or three months (including those who continued physical work) said that cough and sputum had become slight or had disappeared The recommended dose of 20 g P A S daily proved impracticable and had to be reduced to 16 g, or (in most cases) 12 g, but the subsequent M R C report[2] justified this smaller dosage One could be pretty sure that the drugs supplied were taken, since, once he accepted medical advice, a poor Siamese or Chinese would follow it strictly

Where isoniazid and P A S did not fully control cough and sputum, and in the few cases where P A S could not be tolerated, artificial pneumoperitoneum was induced at the chest clinic, provided that suitable arrangements could be made—e g, if a car or ambulance could get near enough to the patient's dwelling to take him home, and if he could receive a certain amount of care at home Though in Britain the use of artificial pneumoperitoneum has latterly declined, in areas such as Thailand, where the tuberculous patient can seldom rest for any length of time, it can still be an important adjunct to drug therapy, reducing cough, and a useful means of preventing extension of the disease after drug treatment has ceased In the second year of the project 275 patients had an artificial pneumoperitoneum

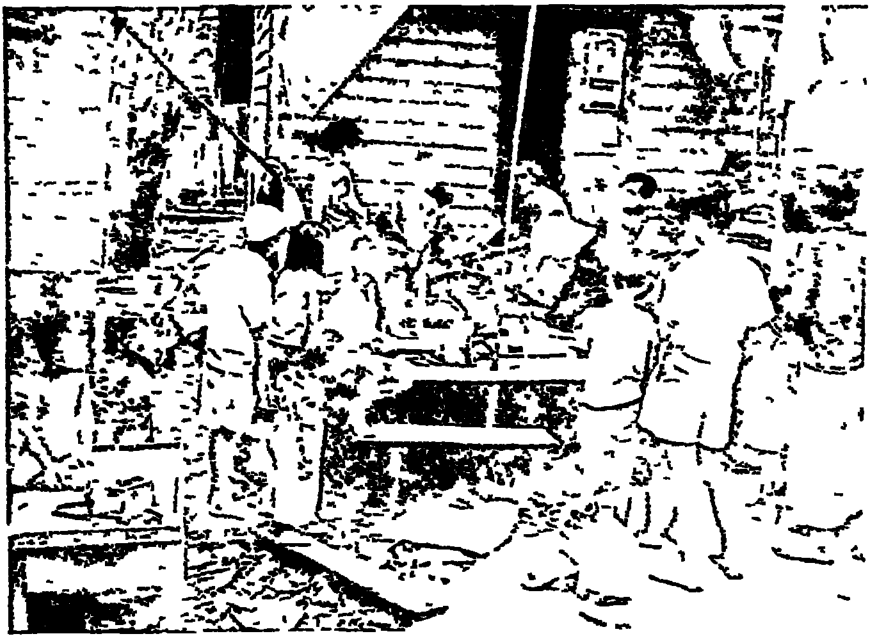

Fig 2—Contacts

"Where a younger patient is immobilised he becomes the focus of attraction for the neighbour's children They are considered as contacts and vaccinated with B C G on the spot"

The patient is the young man in a white shirt, squatting

Note the close proximity of huts, and the cleanliness of the children in contrast to the amount of rubbish characteristic everywhere

Few cases failed to respond to isoniazid and P A S by mouth, or to these drugs supplemented by pneumoperitoneum Unfortunately the time limit set on our project prevented any statistical assessment of the value of these measures, but it was evident that patients receiving this treatment no longer required sputum-containers or toilet-paper handkerchiefs in increasing numbers

Prevention by Conferring Immunity

The contact clinic—This clinic, organised by the W H O public-health nurse, was the first of its kind in Thailand All contacts were tuberculin-tested, and (once the test proved unequivocal) negative reactors were vaccinated with B C G positive reactors under the age of 12 with clinical suspicion of abnormality, and those over the age of 12, were radiographed with a 70 mm film

In trying to ensure satisfactory attendance the nurse encountered many obstacles The elderly could hardly be persuaded to leave their homes for radiography, and as the very old customarily looked after the very young, they were often a source of particular danger Also distances were great in Bangkok a city of bizarre lay out intersected by numerous *klongs* (canals) which made short cuts impossible and caused congestion of traffic Families were usually large and could not afford the fares to the clinic—especially when (as often) the mother was the breadwinner Disruption of communications, by floods and quagmires, during the rainy season was another difficulty Yet with all this the number of contacts attending the clinic steadily rose

Where the contacts could not attend, we sometimes undertook tuberculin testing and B C G vaccination in the patient's home Any tuberculous person who was partially immobilised usually attracted a crowd of the neighbours' children and regarding these as contacts, we sought their parents' consent, and then tested and vaccinated them with the household members (fig 2) Unfortunately, shortage of nurses and transport prevented

CUTHBERT ALLAN SPRAWSON

Kt, C I E, M D Lond, D Litt Lucknow, F R C P

Sir Cuthbert Sprawson, whose death on May 7 at the age of 79 we announced last week, held high administrative and university appointments in India at a time which was important for the future of the medical profession there As director-general of the Indian Medical Service, as professor of medicine in the University of Lucknow, and as the first president of the Medical Council of India he made a lasting contribution to the land which he served for nearly forty years

[Stoneman

He was born at Wimbledon and educated at King's College School and King's College Hospital, qualifying in 1898 Two years later he joined the I M S and at Netley he won the Herbert prize and the Montefiore medal and prize He held posts as deputy sanitary commissioner in the United Provinces and as civil surgeon at Jhansi before he was appointed professor of physiology at Lucknow Medical College in 1911 In 1913 he became professor of medicine at the college During the 1914–18 war he left India to serve as a consulting physician with the Mesopotamia Expeditionary Force In 1919 he was elected F R C P and appointed C I E

In 1920 he returned to his work at Lucknow, and on the formation of the university there he was appointed professor of medicine and dean of the medical faculty The university conferred on him the honorary degree of D LITT, and J W D M writes

"The award of this distinction by an Indian University to an I M S officer may well have been to some extent a tribute to his remarkable personality which ensured for him the friendship and confidence of people of every race and class This power of inspiring trust and affection was also the secret of his ability to maintain harmony among the students of different classes and communities who were living together in the hostel of the college His example of disinterested friendship was far more effective in this respect than disciplinary measures would have been He was an accomplished physician and teacher of medicine, he never ceased to be also a student and a seeker after fresh knowledge '

In 1930 he was promoted major-general and became inspector-general of civil hospitals in the United Provinces and surgeon-general with the government of Madras Three years later he was appointed director-general of the I M S During his term of office the Medical Council of India was set up to establish a uniform standard of higher qualification in medicine for all provinces For the first four years the president of the council was nominated by the governor-general, and Sprawson became the first president He retired in 1937, but his interest and his influence continued He published an important survey of the teaching standards and of the facilities at Indian medical schools which was the basis of an All-India conference in 1938 This conference recommended the gradual abolition of the inferior licentiate medical qualification throughout India, and the upgrading, by stages, of the schools to college status These proposals became effective in one province before the late war interrupted progress, and to some extent paved the way to the commissioning of licentiates as medical officers in the I A M C which was created in 1913

G R McR writes

"Throughout his service it happened that Sprawson occupied posts at a time when events of importance were taking place His appointment to Lucknow University gave him an opportunity to make his influence felt during its critical formative years, in Mesopotamia his experience of the nutritional needs of Indian soldiers and his knowledge of their reactions to disease was complementary to the wider experience of diseases of temperate climates possessed by his British Service colleague, W H Willcox the pair made an admirable consulting team When surgeon general with the Government of Madras he succeeded in opening the teaching hospital to highly qualified members of the independent medical profession as honorary members of the consulting and teaching staffs As director general it was fitting that he was the first president of the All India Medical Council He strove hard to put the new council on a strong foundation before the first non official president, Dr. B C Roy, took charge At all times Sprawson bore in mind the main objective—to prepare for the eventual hand over to Indian successors His work as professor, principal, inspector, and director general was steadfastly directed to that end .

"The pulmonary infection which laid him low from time to time might have daunted a lesser man He carried on resolutely in his own determined fashion—sometimes at odds with those in high places In addition to his official work he was greatly interested in tuberculosis and leprosy work He was a valiant campaigner in both causes while in India After retirement he was an active member of the medical committee of the British Empire Leprosy Relief Association until his death"

Sir Cuthbert married in 1901 Miss Theodora Mary Burton, who died in 1912 He is survived by a son and a daughter

ROBERT PAUL SCOTT MASON

M C, F R C S

Robert Paul Scott Mason, surgeon to the United Birmingham Hospitals, died on May 3, only two days after his 63rd birthday His origins were cosmopolitan, for he was born in Brest of a French mother, and spent his early years in the Far East It was even said that he could speak Japanese before his native tongue These early vicissitudes were due to his father's peripatetic profession, that of a naval officer who had been a wrangler and whose mathematical talents were bent to the science of gunnery Tradition did not dictate that Scott Mason should follow his father's career, after leaving Portsmouth Grammar School he turned to medicine, entering Middlesex Hospital Medical School in 1910, where he came under the influence of Bland-Sutton, Pearce Gould, and Sir Gordon Gordon-Taylor Soon after he qualified in 1915 he joined the R A M C, and as regimental officer to the artillery in the 18th division early proved his remarkable courage, for which he later received an immediate award of the M C His courage was manifest again during the last eighteen months of his life when, though he was seriously ailing, he continued to fulfil his duties both as senior surgeon and adviser within his own hospital, and as vice-president of the Royal College of Surgeons

After the first world war he returned to Middlesex Hospital to work under Sir Gordon Gordon-Taylor then went to Bradford General Infirmary as resident surgical officer before holding a similar position at the Birmingham General Hospital Here his surgical skill soon won the respect of his discerning seniors such as Seymour Barling From the time of his election to the honorary staff of that hospital, and the Children's Hospital in 1925, his reputation as a general surgeon with thoracic interests and a particular facility in gastro intestinal work grew until in his maturity he was recognised in the Midlands as an outstanding abdominal surgeon He was elected to the council of the Royal College of Surgeons in 1946 and in 1955 became a vice-president

B N B writes ' Scott Mason's operating was a delight to behold, being the acme of gentleness, there were never any histrionic flourishes, no alarums and excursions and each was encouraging. Two weeks later a pneumonectomy was done on a male teacher, with unilaterally advanced disease, in whom a previous thoracoplasty had failed. Both patients did well and were back at work long before our team departed. In the subsequent sixteen months other resections, as well as thoracoplasties, were undertaken—106 interventions in all, with 2 postoperative deaths.

Dr Wilson completed the training of a Thai surgeon who had qualified in England and studied thoracic surgery for a brief period in the United States. By the time the American team left after ten months' work the latter was proficient in all major operations. The resident medical officer who had become familiar with the basic principles of anæsthesia prepared himself to go to the United Kingdom on a British Council scholarship. Postoperative adjustment of posture was practised by one of the Thai doctors following the manual of the British Association of Physiotherapists.

When our team began its spade work at the hospital, where it was soon assisted by the American surgical group, there were only two Thai doctors in attendance. But their devotion skill and cooperation was exemplary. Besides taking part in the preparations for building up a surgical unit, attending to all the preoperative and postoperative care, and assisting with operations anæsthesia, and transfusions, they carried a heavy load of nursing duties. Gradually, however, the medical staff increased from two to nine. More nurses were employed, especially aides, since well-qualified nurses were few and far between. A nurses' home was built. The small operating theatre received modern equipment, the wards new beds and nursing requisites. A new two storey hospital block for female patients was added to the bed space, now 130. A small hospital laboratory increased its scope. A modest electrocardiographic department was set up and a doctor was trained in the technique and in the common abnormalities, especially those associated with thoracic surgery. In short, the previous gloom gave way to cheerfulness hope replaced despair and resignation. Coughing was rarely heard on the wards. Patients no longer wore masks—a depressing sight at first. The infection scare was dispelled and the "plague" stigma removed. Instead of wearing their daily clothing in hospital beds, as is common in the East, the patients now had light white garments.

Unfortunately, as there was no provision for rehabilitation, or for social assistance, only those with reasonable home conditions could be considered for major surgery. The Thai team recognised this shortcoming and agreed to set up a convalescent home, with retraining facilities, which would have had the additional advantage of relieving the pressure on hospital beds. Before the international team left, a convalescent home beside the hospital was being planned, but sudden budget restrictions imposed delay.

The Mass-radiographic Survey Near Failure

"Random sampling" was the method chosen to investigate the prevalence of tuberculosis in Bangkok, and the United Nations statistician assigned to the Thai National Economic Council provided the samples. For this purpose, Bangkok was divided into several hundred areas. Of these twenty-four were selected at random for the radiological survey, which was to be combined with tuberculin testing and sputum examination (or laryngeal-swab cultures in the absence of sputum). House to-house propaganda was prepared by sanitarians who explained that in no circumstances would the results be communicated to the employer. But, when an attempt was made to register names, difficulties at once arose. A large proportion of the population were Chinese, who lived under certain legal restrictions, and, fearing political implications, many of them resented an inquiry. It was then proposed to enlist Chinese helpers to explain, but the Chinese comprised at least three groups whose dialects were unintelligible to each other. Tuberculin tests and laryngeal swabs soon became unpopular, and had to be confined to the radiologically suspect. Finally—one of the greatest disappointments—the demographic information arrived rather late. However, before this sampling scheme was undertaken, group surveys had been made frequently in factories and big industrial concerns, and among port personnel and others.

Taking the group and sample surveys together, 16,000 adults were radiographed, and in 5% of these the findings suggested tuberculosis. But bacteriological confirmation was often impossible, for the collection of sputum was fraught with error and the setting up of laryngeal swab cultures unsatisfactory because incubator space was insufficient at the time. All these hazards were aggravated by a succession of technical mishaps, more numerous and harder to overcome than was expected. A further year or two, at least, and the help of international personnel, would have been required to make this survey successful.

The case-finding programme will go on. Advice was given before departure to continue the monthly survey of maternity cases at the maternal and child health centre and to refer to the chest clinic those with a pulmonary lesion.

Teaching and Training

From the beginning we realised that little would be gained by ex-cathedra teaching in English and throughout our two years we taught only individuals or small groups, in question-and-answer fashion. This kept tuition alive, allowed time for repetition and interpretation, encouraged thinking and free discussion, and eased tension and embarrassment. The teacher could soon tell whether he was understood and distinguish between the capable and those who took longer to comprehend. This vast project, with a life-time of a little more than two years, had in the first instance to make use of the ablest and train them to be teachers themselves. Standing rules of the team were to eschew speculations and unproven statements to refrain (above all) from talking down to the students, and yet to be firm and critical.

Of the medical subjects taught, two were given priority first, consideration for the patient's comfort, and, secondly, prevention and management of therapeutic catastrophes.

1 Wherever opportunity arose, attention to the very sick was impressed on medical and nursing staff. Many Thai doctors were as eager as those of other nations to give injections when the real need was comfortable recumbency and fluids. One could not emphasise too strongly the importance of combating pain by simple means, and the benefit of a local anæsthetic for minor interventions—using sharp needles. How to lift, how to feed, and how to give a drink to an immobilised patient were simple but indispensable demonstrations.

2 As tension pneumothorax, empyema, failed surgery, and other complications were at first encountered in considerable numbers, there were opportunities for analysing the causes of failures and the means whereby they could be put right. The importance of fluid and electrolyte replacement and of simple sedation was brought home to the medical staff time and again.

Diagnosis and differential diagnosis of chest conditions was taught in two sessions (to medical staff and visitors) on weekly selected radiological material with all the bacteriological, clinical, and social information. Stress was laid on the pathology of the lesion and on the planning of the stages of treatment. Each case was also considered in all its preventive aspects, the home visitor often being called to the conferences to supply information and receive instructions. Moreover, a two hour teaching ward round was held once a week in which for more than eight months the American thoracic surgeon always joined. Since one was adamant in requesting all the necessary examinations and tests, reports on precautionary measures in the homes, and accurate charts, these ward rounds elicited fruitful discussions, and with many other conferences they became a forum of happy team-

Notes and News

WORLD HEALTH ASSEMBLY

THE ninth World Health Assembly opened at Geneva on May 8, and it is expected that it will continue till May 26 The medical members of the United Kingdom delegation are Sir John Charles, Sir Eric Pridie, Dr H K Cowan, and Dr M T Morgan

In his inaugural speech Prof Jacques Parisot (France), the president, pointed out that national economics were based on human economy and that the productivity, welfare, and strength of a country were related to the "health capital of the population" To improve health on an international level governments and peoples must unite The world was growing smaller every day, inequalities in health were a danger to all and we needed a world wide offensive not only against diseases of the body, but also against diseases of the mind and against the social inequalities which breed conflict He was therefore especially glad to be able to welcome several new members to the World Health Organisation Morocco, Tunisia, and Sudan were admitted to full membership and the Gold Coast, Nigeria, and Sierra Leone to associate membership Professor Parisot regretted that the U S S R 's resumption of membership had been postponed

Mr Milton P Siegel, the assistant director general in charge of finance, was able to give an encouraging report of his department The financial position of W H O , he said, was the best since its start in 1948 During 1955 92% of the total contributions due had been paid and substantial arrears collected Dr M G Candau, the director general of W H O , reminded the assembly that the 1956 programme had had to be adapted to the budgetary level approved for 1955, though this did not meet even the minimum demands of member States He hoped that the assembly would make it possible to meet those needs in 1957

THE ROYAL SOCIETY

THE president and council of the Royal Society received guests at the annual conversazione on May 10 at Burlington House, where Science's latest was on exhibition For those anxious to catch up with what had been going on in scientific corners other than their own the evening was as attractive as usual And for those who felt that they were too far behind to catch up with anything, there were many encouraging exhibits which gave a nice straightforward picture of such delights, for example, as the ceiling temperature phenomenon in addition polymerisation reactions

Vitamin B_{12}, looking rather like an unknown political prisoner in some of the models, was the star of an effective demonstration arranged by Dr Dorothy Hodgkin, Dr E Lester Smith, Prof A W Johnson, and Sir Alexander Todd By a combination of chemical and crystallographic evidence, the structural formula of B_{12} has been deciphered The calculations established the presence in the molecule of a planar fragment with a structure clearly related to porphyrins, though in a quite unexpected way Nearby Prof W D M Paton was considering the chemical transmission of nerve effects in the isolated intestine No one had been certain which of the muscle stimulants in the wall of the small intestine transmitted activity from the nervous structures there to the smooth muscle By placing one electrode within the lumen and one outside the guineapig ileum, vigorous twitches were obtained with single shocks of 0 5 millisecond, and the preparation was found to be cholinergic in its properties Moreover when the tissue was treated with eserine, stimulation caused acetylcholine to appear in the bathing fluid in sufficient amounts to cause another unstimulated piece of intestine to contract

The kaolin model glaciers were a great success and several enthusiasts regretted that they had left their ice axes and crampons at home Mr W V Lewis and Mr M M Miller, of the department of geography at Cambridge, worked hard at their model ice falls down which they urged a mixture of one part kaolin to two parts water The kaolin glaciers crevassed and flowed realistically, and dust was scattered on the surface to illustrate the movement of the summer accumulation between the cleaner snows of winter The crowd watching the glaciers became so thick at times that they threatened to upset another formidable display of Nature's ingenuity—the model of the molecule (or rather a small part of the molecule) of deoxyribose nucleic acid, which had been constructed at the biophysics research unit of Ki College, London This strange substance seems to hold s of the secrets of the transmission of hereditary cha teristics, and it may be that the arrangement of the atom the molecule forms a sort of "code" for the transmissio information from one generation to the next

Those who feel that evolution is a dull business, which aggravatingly failed to attune itself to the pace of mod life, should see Dr H B D Kettlewell's splendid f *Evolution in Progress*, the story of natural selection "industrial melanism" About 70 species of moth in country are at the moment in the process of changing t complicated wing patterns, intended for concealment lichened tree trunks, boughs, or rocks, to all black, whic better suited to the dirty bark of industrial areas This first noted about 1840, and the rate at which the black fo are spreading is the most striking evolutionary change witnessed in any living organism Dr Kettlewell's study these moths and the birds that prey on them was viv illustrated in the film, which was taken by Dr Niko Tinberg It showed how the birds are responsible for the vir elimination of the white moths from polluted countryside how, in districts with purer airs, the black forms are the o that get plucked from the clean lichened tree trunks

THE DESERT AND THE ROSE

WITH increasing populations the world's need of fo continues to increase[1], and, because there is not mu unoccupied tillable land available for agriculture, mo attention has been given to the possibility of breeding cat and growing crops in the deserts

In 1952 the Institute of Biology organised a symposiu on the biology of deserts, and its proceedings have sin been published[2] Prof Frank Debenham points out th deserts are characterised by extreme heat by day and extrem cold by night, requiring special adaptation in their fau and flora Brigadier R A Bagnold, F R S , goes into t question of water supply and shows how man and the larg animals depend on nomadism for their existence in deser Prof F W Shotton discusses the use of the undergrou water which is usually too salt for irrigation Dr H Bo reminds us that, even if we find new sources of food in th natural vegetation of the deserts, the commercial productio of them would be a complex problem, and Prof Pa Vayssière shows that, as soon as introduced crops beg to grow, locusts immigrate to devour them Tackling deser from a different angle, Prof E P Stebbing explains how th arise and how to stop existing deserts from expandin Dr J S Weiner discusses man's adaptability to the dese and claims that "disorders occurring purely as a resul of the climate are to a large extent preventable and a matte of fairly simple hygiene", but Dr Edmond Sergent argue that it will not be feasible for either white or black colonist to *labour* in the desert Whites could do the administrati work but could not till the soil The only possible tillers of th soil of the deserts are the present inhabitants of those desert who will have to be helped to multiply so as to provid enough agriculturists Mr S M Manton, F R S , describe what he saw on a visit to Russia afforestation scheme hydro electric developments for irrigation of Asian deserts the tapping of underground water supplies, and improved methods of cultivating the deserts The new areas to be irrigated are said to equal in extent a third of the world's irrigated land, and the Russians hope that this transformation of the scene will produce for them a better climate, which in turn will enable more crops to be grown

These are grandiose schemes, but do they constitute the right way of tackling the question of increased food supplies Prof Hugh Nicol[3] holds that, in relation to the work it demands—making the underground water supply available and arranging to drain it away, mining and grinding and transporting the necessary gypsum for dressing the land and providing the fuel for all that—conversion of the deserts into agricultural land does not give an adequate return in food He points out, too, that industry, transport, and food production are in competition for a limited supply of fossil fuels phosphatic fertilisers *could*, with difficulty, be made other hospitals and medical schools, and consideration and care for the sick is propagated in pursuance of the W H O team's teaching

[3] Nicol H Microbes and Us Pelican Books 1955 Pp 2 2s 6d

Hence the answer to my question ' Was it justified ? " is "Yes"—though with reservations The period of a little more than two years was much too short a time in which to complete and consolidate the work Though several doctors, nurses, and technicians were adequately trained, there was still a difference between those who had been trained and those who were ready to assume responsibility—and the latter were not numerous Every project needs a trial period during which criticism must be allowed though it may necessitate staff changes on either side Many Thai members had joined in the hope of eventually gaining a W H O fellowship abroad , and when this hope faded they had no special incentive left It was recognised too late—after all possible efforts had been made, and temporary improvement achieved—that we could not hope to secure the services of a sufficient number of qualified home-visiting nurses This state of affairs called for a change of policy A health-education programme should have assisted the campaign of prevention The first steps towards this end were taken by instructing students, and similar activities were in preparation , but time was too short for the scheme to be pursued Health education could have done much , for, from the public health point of view, the bodily cleanliness of the people—even of the poorest and their children—was an important asset On the other hand their canals were dirty, and their environmental sanitation deplorable

“IF I WERE ”

“If I Were Team leader” again of a tuberculosis control project, with the same facilities at my disposal, I would follow essentially the same pattern of planning for diagnosis and prevention and again aim at incorporating the tuberculous patient as a useful member of the family to which he belongs But I would ask my headquarters to consider the following points

1 Do not start a project until all the necessary equipment has arrived

2 Engage international staff in good time and arrange for language lessons pertaining to the country of assignment

3 Impress on the government the need to select able counterparts, because they will have to be the teachers of the future

4 Do not send a team without clerical help to a country where English is not the basic language

5 See that sufficient transport is available, assess the requirements for health visitors, and double the number of vehicles required by them Without satisfactory transport a domiciliary service in a hot climate cannot work and exhausts its members

6 See in time that the government is prepared to pay a good salary to drivers Bad drivers quickly ruin the cars

7 Allow doctors and nurses to drive vehicles, and insure them

8 Make sure that the government is willing to pay adequate salaries to technicians and nurses , for a project stands or falls by their skill, reliability and devotion

9 If after a certain period it emerges that nurses cannot be recruited for a tuberculosis project and salaries and amenities remain unsatisfactory, one had better prepare for a health-education programme in good time by employing lay personnel in large numbers on the model of a mass-B C G campaign

10 A tuberculosis project must have a social worker who will collect facts and figures, arrange for assistance and rehabilitation, and tap new resources

11 Impress on the government not to spend money on any major building programme until sufficient medical, nursing, and technical staff are trained One should expand in a cautious way, gain experience until the time when all requirements are clear, and then begin to make plans

12 Prepare convalescent homes with retraining facilities for the patients Such a scheme will also help to relieve pressure on hospital beds Convalescent homes can be administered by less qualified doctors and nurses

13 Where tuberculosis is widespread, arrange early for children's wards for the treatment of tuberculous meningitis, miliary infections, and infections of adult type

14 Never again embark on a tuberculosis control project of only two years' duration

---

Conferences

ATLANTIC CITY MEETINGS

FROM A CORRESPONDENT

THREE important meetings are held annually in Atlantic City in the spring They are the gatherings of the American Federation for Clinical Research, the American Society for Clinical Investigation, and the Association of American Physicians This year the weather was kind and the boardwalk crowded between meetings Brief reports of a few of the papers follow , full reports will be published later in the journals of the respective societies

Studies on the L E cell phenomenon were reported by N B **KURNICK** He concluded that the abnormal factor present in the γ globulin of these patients alters the cell membrane so as to allow entrance of a serum proteolytic enzyme, which then destroys the inhibitor of desoxyribonuclease (DNase) This enzyme then attacks the chromosomes, yielding the depolimerised nuclear mass which characterises the L.E phenomenon He treated 16 patients with homologous whole blood (or leucocyte homogenates) intramuscularly, thus providing material which may either supply DNase inhibitor or adsorb circulating abnormal γ globulin (or both) Encouraging results were seen, and steroids could be withdrawn in almost all cases

J A **MOORHOUSE** and R M **KARK** reported their observations on the effect of tolbutamide (orinase) on blood-sugar levels during continuous feeding with first glucose and then fructose With glucose no effect was seen, whereas blood-sugar levels fell promptly with fructose They concluded that a primary effect of the drug on the liver had been demonstrated and that the data did not support a direct tissue action

G W **LIDDLE** J E **RICHARD**, and G M **TOMKINS** gave an account of the biological effects of a new series of corticosteroid analogues in which carbon 2 is methylated By this means the effects were greatly enhanced , the most potent member of the group (2 methyl-9 alpha fluorohydrocortisone) was three times as powerful as aldosterone, and the most effective mineralocorticoid yet described

C J **FISHER** and W W **FALOON** showed[1] that blood-ammonia levels in liver cirrhosis can be controlled by giving 12 g of neomycin orally daily This dose prevented mental effects, and allowed more protein to be given in the diet

A useful test for steatorrhœa was described by J **WENGER** and E C **TEXTER** They made a single determination of the blood carotene level, and showed its relationship to the 24 hour fæcal fat excretion It seems clear that, provided the carotene intake prior to the test is adequate, low levels imply some defect of fat absorption The simplicity of the procedure may make it a useful screening test for steatorrhœa, and an easy means of following the course of the disease

The first case of pyridoxine responsive anæmia in the adult was recorded by J W **HARRIS**, J M **PRICE**, R M **WHITTINGTON**, R **WEISMAN**, and D L **HORRIGAN** It appeared as an apparently unresponsive iron deficiency anæmia, without tongue or nerve involvement, and with no skin changes Hæmatologically the essential lesion was a reduced mean corpuscular hæmoglobin concentration with raised serum-iron level Pyridoxine hydrochloride (200 mg intramuscularly daily for five days) produced prompt remission, with a reticulocytosis of 50 8% on the seventh day After relapse had been allowed, it was shown that a similar but much less striking remission could be obtained with pyridoxine orally A specific defect in absorption of the vitamin was suggested as the cause

British Association for the Advancement of Science

The annual meeting of this association will be held in Sheffield from Aug 20 to Sept 5 Further particulars may be had from the association, Burlington House, Piccadilly, London, W 1

British Epilepsy Association

The annual meeting of the association will be held on Thursday, May 31 at 2 30 P M, at Manson House Portland Place, London, W 1, when Sir Henry Cohen will speak

The Doctor as Witness

On Monday, June 4, at 8 15 P M, at the Marlborough Day Hospital, 38, Marlborough Place, London, N W 8 Dr J C M Matheson principal medical officer of Brixton Prison, will speak on the Doctor as Expert Witness in Criminal Courts

London Amateur Boxing Association

A meeting of the medical officers of this association will be held at the Great Northern Hotel, King's Cross, London, on Thursday May 31, at 7 30 P M, when Mr Ian Robin will give a talk on ear, nose, and throat injuries

Convalescent Home for Diabetics

A convalescent home, which is open to male diabetics over 12 years of age from all parts of the country, has been opened by Sheffield Regional Hospital Board at Langwith Lodge Nether Langwith, Notts Application forms are obtainable from the matron

Growth and Development of Children

The annual meeting of the teams engaged on coördinated research on the growth and development of children will take place in London on July 9 and 10, at the Child Study Centre, Brunswick Square, W C 1, under the chairmanship of Prof Alan Moncrieff These annual meetings are sponsored by the Centre International de l Enfance, Paris It is hoped that representatives of teams from London, Paris, Zürich, Brussels Stockholm, Kampala, Dakar, and Louisville will be present

W H O Appointments

Dr Jessie Bierman, professor of maternal and child health at the University of California School of Public Health, has been appointed to the headquarters staff of the World Health Organisation as chief of the section of maternal and child health The appointment is also announced of Dr E E Krapf, associate professor of psychiatry in the University of Buenos Aires, as chief of the mental health section

North of England Otolaryngological Society

The prize which this society offers for original work in otolaryngology carried out in the North of England during the tenure of a senior registrar, registrar, house officer or clinical assistant post has been awarded this year to Mr R W Bailie for his paper on Lermoyez syndrome Entries for next year should be sent to the hon secretary, Mr R Thomas, 27 High Petergate, York, before Aug 1, 1957

Joint Cancer Consultation Clinics

The experiment in cancer treatment first organised by the Royal Marsden Hospital (then the Royal Cancer Hospital) in 1944 was described in our annotation of May 5 On May 11 and 12 the cooperating hospitals held their first general meeting, and there was a dinner to celebrate the 12th anniversary of the inception of the joint clinics Mr J M Wallace, a governor of the Royal Marsden Hospital, was in the chair, and Miss Patricia Hornsby Smith parliamentary secretary to the Ministry of Health was the chief guest Proposing The Cooperating Hospitals Scheme she said it was as much a matter of human relations as of science, and it had added a new dignity and meaning to the oft repeated precept that the patient came first Speaking of nuclear energy in medicine Miss Hornsby Smith emphasised the value of the work going on in many different hospitals and laboratories she often had to answer aggravating questions from people who assumed that research began and ended in the laboratory at Mill Hill Sir Max Page replied on behalf of the hospitals Prof D W Smithers welcoming the guests, wondered whether the joint clinics might not prove to be a pilot scheme for other regions and other specialties Sir Harry Platt responded for the guests

R A F Appointments

The following appointments in the Royal Air Force hav been announced Dr D Evan Bedford, civilian consulta in cardiology, Prof C V Harrison, honorary civilian co sultant in pathology, and Mr C Naunton Morgan, civil consultant in surgery

Appeal to Congress Organisers

One of the objects of the Council for International Orga sations of Medical Sciences (C I O M S) is to coördinat international congresses of medical and related science T avoid overlapping, congress organisers are asked to infor the C I O M S (Unesco House, 19, Avenue Kléber Paris 16 of their plans before fixing the dates of their meeting

Education of Subnormal Children

On May 9 Mr Dennis Vosper, parliamentary secretary to the Ministry of Education opened a school for educationally subnormal children in Brighton Provision for these children had been increased since the war but about 12,500 children were still waiting admission to special schools Though most of them were in ordinary schools Mr Vosper said that a further 75 special schools, providing nearly 9000 places were in course of construction or had been authorised Though the number of special school places had increased by 10,000 since 1949 the number of children awaiting places had remained almost constant "This clearly shows," Mr Vosper said "that we are all taking greater trouble in ascertaining the existence of this form of handicap Children who previously might have been left to cope alone with their disability are now seen more clearly to need assistance"

British Society for Research on Ageing

The annual meeting of this society will be held at the Ciba Foundation, 41, Portland Place, London, W 1, on Friday June 8, at 4 P M This will be followed by a scientific meeting open to non members when Prof K J Franklin and others will speak on reactions to standard stimuli at various ages and Miss Honor Fell, F R S, on the effect of vitamin A on embryonic epidermis of different ages

A joint meeting with Dutch Gerontologists in Amsterdam has been planned for July 27 and 28, before the International Physiological Congress in Brussels on July 30 Further particulars may be had from Mr G H Bourne, D SC, London Hospital Medical College, Turner Street, London, E 1

The Royal College of Surgeons of England have sent their congratulations to Mr Gerald S Hughes of York who has completed 50 years as a fellow of the college

Central Council for District Nursing in London —The council has published a supplement to their directory and streets list The supplement includes new blocks of flats and the roads which serve them Copies (1s 6d) may be had from the council, 25 Cockspur Street S W 1

A new edition of the Home Office pamphlet on *Duties of Doctors and Dentists under the Dangerous Drugs Act and Regulations* has been issued (H M Stationery Office Pp 16 9d)

woman under forty was present, and the overpowering majority either wore spectacles or had some other more or less conspicuous physical defect One poor gentleman came in on crutches, another had the rolling eye of "inherited tendencies", and the little linen that was present was evidently on enforced leave from the wash tub

At first the "casual" thought the audience had collected itself as an outward and visible sign of the dire necessity for "improvement", and as a protest against the sins of their fathers who had taken no heed of the matter But as the meeting advanced and the view was delicately unfolded that marriages should be made with an eye more to the physical development of the race than to wealth, or beauty, or love, the "casual" found that he was grossly mistaken—the audience was there to protest against any interference with their individual freedom in matters of love and marriage One gentleman of ninety-odd emphatically and with many a senile tremor declared to his junior by a decade "we are not going to marry to please the State but to please ourselves" Another gentleman from the audience bounded on to the platform and with a tongue which sadly needed the agility of his toes, stammered that so long as there was 'L l l l love in the w-w w w world l l l-l love w w w w would l l l l laugh at l l-l l locksmiths"

The sides of the few complete men and women who were present now began to ache But that ache was nothing to the acute agony to which they were soon put at the hands of no less a person than the very celebrated professor, the man of science and world wide fame, who for more than half a century has been the brightest star in matters anthropological and whose paper on "Eugenics" it had been the object of the meeting to hear

The professor has a face of serene calmness and philosophical divinity, and his expression is one of angelic graciousness No more than a glance is needed to recognise that he is not as other men As the disembodied soul is to common clay, so is Professor Galton to the rest of humanity

That is what the casual enquirer thought After several male members of the audience had appeared upon the platform to criticise the "able and interesting" paper which the professor had read, a lady rose She was past the bloom of life and wore a large hat and spectacles

The professor bowed and courteously bent his head in the direction of the lady But a cold together with the changes which years are prone to work in the auditory canal, had impaired his hearing powers to such an extent that listening was palpably an effort, and he soon gave up the attempt and leaned back in his chair On the professor's left sat a young man already known to fame, and to him the great man turned—and then the audience occupying the few front rows of chairs were electrified, petrified, and almost electrolysed, by hearing his dulcet tones form the words "Fancy having a wife like that!"

The young man blushed The chairman turned a horror-struck countenance on the professor The lady paused The professor was the only unconcerned person on the platform He turned his divinely imperturbable face towards the chairman as though he would ask "Has she said anything very dreadful?" For one brief second the quivering silence lasted, and then (to her everlasting honour be it said) the lady resumed her remarks as though there had been no interruption

The paper of the learned professor had proved beyond the possibility of a doubt that men and women were perfectly ready to be influenced in their choice of each other by "Eugenics" But amongst the many arguments which were advanced against this theory there was none so overwhelming in its conclusiveness as those six little words which slipped so naturally from the professor's own lips "Fancy having a wife like that"

When the Man of Science judges by appearances what is the Man in the Street to do?

IODINE AND FLUORINE

The nutrition panel of the food group of the Society of Chemical Industry held on April 11 the fourth and final meeting of a series concerned with Nutritional Requirements and Food Fortification [1]

Iodine

Prof Margaret Murray said that iodine had been recognised as a nutritionally essential element since Baumann in 1896 prepared "iodothyrin" from the thyroid gland and it was shown that its iodine content ran parallel with its physiological activity The iodine of the diet, which was mainly in the form of iodide, was taken up by the thyroid cells for the production of thyroxine and tri iodothyronine An inadequate intake of iodine led to thyroid dysfunction and goitre Because iodine was not abundant in foods generally, its level in drinking-water determined the adequacy of its supply Although inadequacy of iodine was the ultimate cause of most endemic goitre, other dietary factors, present in particular in the brassicæ, could act as goitrogenic or anti-thyroid agents In addition calcium could be goitrogenic The iodine requirement of man had not been accurately determined but was generally accepted as 100 µg per day The iodine of drinking-water was a critical factor in achieving this intake and 5 mg per litre was regarded as an adequate level

Mr J C M Holman discussed the use of iodised salt for goitre prophylaxis He emphasised that iodine must not be regarded as a cure for established goitre but largely as a prophylactic Many methods for goitre prevention had been tried including the use of iodised salt, the addition of iodine to water supplies, the administration of iodised tablets and sweets to school children and the application of iodine-rich fertilisers to vegetable crops Of these methods the iodisation of salt was the most satisfactory and had now been practised for over thirty years Remarkable decreases in goitre incidence had followed the introduction of iodised salt in many countries including the U S.A, Switzerland, New Zealand Colombia, and Poland No adverse effects had been observed In Britain iodised salt was available but not yet compulsory, although the Government had announced in 1950 its intention to implement the recommendation of the Medical Research Council that all free-running salt in domestic use should contain 1 part of potassium iodide in 40,000 parts of salt Iodide added to salt was stable for over two years if the salt was kept dry and free-running and contained a stabilising agent The desirable level of iodisation was determined by the average intake of salt and the average dose of iodine necessary to prevent goitre in a community There was accordingly wide variation, from 1 in 10,000 parts to 1 in 200 000 parts of salt, in different countries

In reply to a question on the possibility of iodisation leading to excessive intakes of iodine, Professor Murray pointed out that the levels used in fortification were far lower than those naturally in sea-foods, there was no evidence that iodisation constituted a danger

Fluorine

Professor Murray remarked that fluorine had not been shown to be essential for animal nutrition since no fluorine-free diet had yet been obtained Fluorine was found in varying amounts in the calcified tissue of the body, the amount increasing with age and fluorine intake Fluorine also accumulated in fossil bone and teeth, and the estimation of fluorine in fossils was an accepted method of dating them Fluorine was also present in the ash of kidney stones One of the chief sources of fluorine was drinking-water Most water-supplies in Britain contained less than 1 part of fluorine per 1,000,000, but there were several places with values of 2–3 parts per 1,000,000 In such areas the intake might amount to 3–4 mg daily from water The only foods rich in fluorine were sea-foods and tea The toxic level of intake of fluorine depended on its absorption and the efficacy

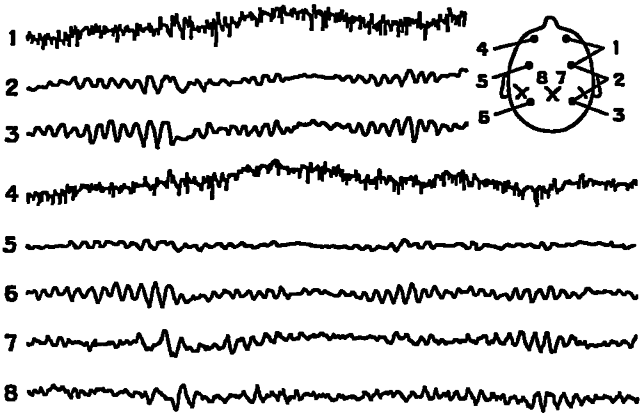

Fig 2—Electro-encephalograms from case 1, showing slow waves

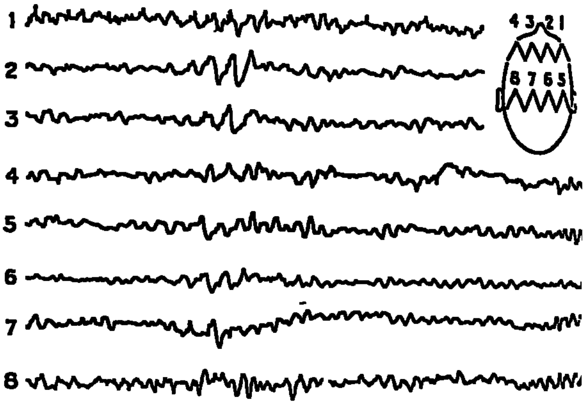

Fig 3—Electro-encephalograms from case 1, showing paroxysmal episode

Many were of long duration (up to 15 msec), polyphasic, and often of large amplitude (1–2 µV) In some instances where muscle weakness was severe all the residual motor units were abnormal and grouped, the volitional pattern being distinctive (fig 1)

These changes, described by Bauwens (1955) as typical of an early myelopathic lesion, are common to many diseases in which the lower motor neurone is involved at the cord level, but in our cases the absence of evidence of lower-motor-neurone degeneration, in the presence of prolonged paralysis, is striking, ruling out the possibility of poliomyelitis as the cause Cases of old post encephalitic parkinsonism were not found to show these electrical reactions

ELECTRO-ENCEPHALOGRAPHY

5 patients showing serious disorders of behaviour were electro encephalographed All were abnormal, and the abnormality was of a similar kind, with the presence of some bilateral activity in the 4–7 c/s range, in addition, 2 showed slower episodic activity Probably at the comparatively late stage at which the examinations were made the electro encephalographic changes observed were entirely non specific Similar abnormalities have been observed in patients with encephalitis lethargica

Two specimens of an electro encephalogram in the most severe case in the present series are shown in figs 2 and 3 The recording shows a fairly regular and partially responsive alpha rhythm at 10 cycles per sec in the postcentral leads at potentials up to 50 µV, sometimes spreading forward to the frontal leads It was associated with occasional slow waves at 3–5 cycles per sec , which were more prominent in transverse recordings, where occasional waves in short runs at about 6 cycles per sec occurred somewhat paroxysmally In all areas there were faster frequencies at about 20–24 cycles per sec at a low potential Being slight the abnormalities could be constitutional Repeat electro encephalography six months after the onset showed little change, as might be expected from the patient's clinical state Further examinations may determine whether the observed abnormalities are due solely to the present illness

This patient was also subjected to psychometric testing, which revealed organic impairment of the brain She showed some anxiety in the test situation, accompanied by an obvious desire to talk about her emotional problems

Case-reports

Case 1—A married female domestic worker, aged 44 developed an infection of the upper respiratory tract on April 14, 1955 On April 18 she complained of headache, lassitude shivering and cough and was admitted to the unit on April 20

On admission she was apyrexial, but her face was flushed She complained of severe headache and pain in her left leg, was mildly confused, and appeared to be uncoöperative probably because she could not maintain her attention when questioned She kept grimacing, making masticatory movements, and licking her lips Continuous clonic twitchings of the left side of her face and of her left sternomastoid muscle slight right ptosis, and bilateral weakness of her palate were present She had moderate neck rigidity with a positive Kernig sign The muscular tone in her legs was slightly increased, and her tendon reflexes were exaggerated Her abdominal reflexes were present but diminished , her plantar responses were flexor

Subsequent Course—Irregular pyrexia not exceeding 99 4°F persisted throughout her stay in hospital On the first day she had difficulty in swallowing fluids, but this did not recur The facial manifestations, including ptosis, gradually subsided after the first week Cramp like and distressing myoclonus affecting her entire left leg masked the paresis throughout her stay in hospital Her plantar responses became extensor, the right on April 22 and the left on April 25, and returned to normal only after two months Sensory disturbances were not observed, but her calf muscles and left quadriceps muscle were occasionally tender

Follow up—On Jan 10, 1956, clonus persisted in her left leg, and the electromyographic findings (fig 1) were unchanged She said she was liable to " cramp " in her left leg

Case 2—An unmarried female typist, aged 26, with five weeks' history of bilateral loin pain, radiating toward the groins, lasting for a few minutes at a time, of variable severity, and unrelated to exertion, and three weeks' history of frequency and dysuria had had her kidneys fully investigated at another hospital, where nothing abnormal was found and she was discharged with a diagnosis of " hysteria " Three days later on July 26 1955, she was admitted to this unit with severe headache, stiffness of her neck, backache occasional pains in her cervical and left dorsal regions, and weakness of her left hand and wrist In addition, she complained of a sense of pressure over her head, blurred vision severe vertigo, a feeling of heaviness in her legs, shoulders and upper arms, and what she described as a tremulous weakness most pronounced on her left side

On admission her temperature was 99°F She was thin and looked anxious, and a coarse intention tremor of slow rate and moderate amplitude affected her head and arms Slight generalised weakness was present in her left arm and leg her deep reflexes were normal abdominal reflexes present and plantar responses flexor Anteflexion of her head caused discomfort in the posterior cervical muscles, but true meningism was absent, Kernig's sign being negative No sensory loss was noted Both loins were tender, an enlarged gland was found in the left posterior cervical region and tonsillar glands were slightly enlarged

Subsequent Course—During the following week headache and general tremulousness increased accompanied by a lo of positional sense in the left foot The patient complained of severe pain in the lower lumbar region, radiating to the left buttock and thigh and aggravated by movement Complete loss of sensation to pain and light touch was noted from the mid calf level Joint sense and vibration sense were also impaired All tendon reflexes were depressed, the right

G M C ELECTION

SIR,—Because we think that younger men should take part in the leadership of the medical profession, my wife and I voted only for Dr Whiteside and Dr Dillon If others of like mind were to vote only for the younger, unsponsored, candidates and refrained from entering any votes for the official candidates, this might counter the heavy pressure of B M A canvassing and give the younger man a fairer chance

Port Talbot, Glamorganshire   R A ROBERTS

SIR,—I am in entire agreement with Dr Whiteside and Dr Dillon It is wrong that our money in the B M A should be used to canvass votes for men standing for the G M C I admire the pluck of these two who dared to stand against the "old brigade" May I wish them better luck next time on behalf of the 16,000 who voted for them

BASAL HORIZONTAL LINES ON CHEST RADIOGRAPHS

SIR,—In mitral stenosis attention has been paid to the lungs as well as to the heart, and the horizontal lines seen in radiographs in the lower lung fields have attracted particular attention Dr Rossall and Mr Gunning (May 5) show that these lines are of clinical significance, indicating a disturbance of the pulmonary circulation of such a degree as to warrant valvotomy These lines, therefore, are sufficiently important that their anatomical counterpart should be clearly understood, and I write to correct a misunderstanding by Rossall and Gunning

They refer to papers of mine[1] and others[2] and speak of "accumulation of tissue-fluid in *interalveolar septa*" as the cause of the lines, but this is a misquotation I have shown, by comparison of radiographs and lung sections, that pathological changes in the *interlobular septa* are responsible for the lines Œdematous alveolar walls would be of such microscopic size that they would not show up as lines recognisable in radiographs The anatomy underlying the lines is that of the septa between lung lobules (which are also called "secondary lobules" by Miller[3]) and which are the smallest units of the lung separated from their fellows by fibrous septa These lobules are of various sizes but, on average, about 1 cm in diameter Kerley[4] thought that the interlobular septa were too short to account for the lines, but, in large sections prepared by the Gough and Wentworth technique, the septa can be readily traced from one lobule to the next deep into the lungs When the interlobular septa are sufficiently parallel to the X ray beam, and at the same time pathologically thickened, or laden with hæmosiderin or radio opaque dust, they will show up as lines In the septa is one of the systems of lung lymphatics, and Kerley is right in saying that these lymphatics are distended but the main bulk of excess fluid is in the connective tissue of the interlobular septa, which become widened

I agree with Rossall and Gunning that the rise of the left auricular and pulmonary venous pressure rather than the rise of the pulmonary arterial pressure is the cause of this interlobular septal œdema, and I think the following is the mechanical explanation In the interlobular septa are the pulmonary veins, and I have found these distended at the inner ends of œdematous interlobular septa The distended veins may have obstructed the lymphatic flow, and fluid which normally runs centrally is diverted towards the pleura This latter route is a normal one for the superficial part of the lung, but it may have to carry a larger volume of fluid when the pulmonary veins are overdistended When the volume is too great, the lymphatics become distended and the surrounding interlobular septal tissues become œdematous Such an explanation would account for œdema of the interlobular septa in the absence of œdema of the air spaces Bruwer et al[5] have also suggested, on theoretical grounds, that distension of pulmonary veins may cause lymphatic obstruction

Welsh National School of Medicine
Cardiff   J GOUGH

SIR,—The excellent paper by Dr Rossall and Mr Gunning provides yet further evidence to support the thesis previously presented[6] as to their pathological significance

Rossall and Gunning deal only with the production of this radiographic sign in cardiac disease (and particularly in mitral disease), and show that its presence is related to a dangerously high left auricular pressure In cardiac disease the lines indicate a state of pulmonary capillary, venous, and left auricular hypertension usually secondary to mitral disease or left-heart failure, and they provide a warning of impending alveolar œdema These lines, however, occur in many other states in the absence of cardiac disease or of pulmonary hypertension

There can be no doubt that they are caused by œdema (and later organised thickening) of the peripheral interlobular pulmonary septa[1 2 6 7] Œdema of these septa is produced by exactly comparable mechanisms to œdema elsewhere in the body—e g , the soft tissues of the legs

(*a*) Œdema may be produced by an increased capillary hydrostatic pressure This pulmonary capillary hypertension is usually secondary to the increased pulmonary venous and left auricular pressures due to mitral stenosis In mitral disease, therefore, the occurrence of this radiological sign indicates pulmonary capillary hypertension and provides a valuable indication for intensive treatment including valvotomy[6] In pulmonary arterial hypertension secondary to congenital systemic pulmonary vascular shunts, the capillaries are usually protected from the hypertension by the rapid fall of blood pressure in the narrowed pulmonary arterioles As Rossall and Gunning show, it is well known that in these cases of pulmonary hypertension secondary to congenital heart-disease, the pulmonary capillary and left auricular pressure rarely exceeds the plasma colloid osmotic pressure of 25 mm Hg, and therefore pulmonary interstitial œdema and its corresponding radiographic sign do not occur In left heart failure, however caused, the lines may be seen when the pulmonary venous and capillary pressure is sufficiently raised[6 8]

(*b*) Œdema may be caused by lymphatic blockage, as in mediastinal reticuloses, sarcoidosis, pneumoconiosis, lymphangitis carcinomatosa and possibly bronchiectasis When the impairment of lymph drainage is sufficient to cause œdema of the pulmonary interstitial tissues, the identical horizontal lines are seen on the radiographs

(*c*) Œdema may be caused by increased permeability of the capillary membranes This change occurs in pulmonary[9] as well as in systemic capillaries and explains the occasional occurrence of these lines in chest radiographs in acute nephritis (even in the absence of left heart failure), allergic lung conditions, and exposure to toxic gases

(*d*) Œdema may be caused by reduced plasma colloid osmotic pressure, as in hypoproteinæmia, and although I personally have not seen these transverse lines in this condition they should theoretically occur

In (*d*) and particularly in (*c*) the illness may be acute, and it is likely that the interstitial pulmonary œdema may be obscured by the accompanying alveolar œdema

Follow-up —On Nov 23 and Dec 22 she still had muscle weakness, walked with a limp, and was easily fatigued, sensory loss was still present On Jan 13 her right leg was still stiff and weak, and her knee jerks were still much exaggerated, but her general condition had improved

Case 8 —A girl, aged 9, complained of headache and nausea on Oct 15, 1955, and had a temperature of 100 8°F She had tenderness of her calf muscles but no neck rigidity, and all her reflexes were present Next day she vomited once, her legs ached and could not bear her weight, and she was admitted to the unit

On admission she was apyrexial, and she remained so throughout her stay in hospital Both legs were weak, the right more than the left Her leg reflexes were within normal limits Much muscle tenderness in both calves was noted

Subsequent Course —Both ankle and knee jerks became exaggerated, and weakness, particularly of dorsiflexion, increased on the left side Seven days after the onset the legs became more painful and there appeared to be spasm in the calf muscles After a further week paresis abated, and three weeks from the onset the patient was walking well and was free from pain

Comment

In all the recorded outbreaks of cases like the foregoing the investigations have been hampered by the fact that there have been no deaths and no infective or toxic agent has been found Unlike the cases previously recorded, however, the present cases were sporadic and, so far as could be ascertained, did not give rise to any outbreaks Inquiry at other fever hospitals did not reveal any similar experience, but, in view of the difficulty of diagnosis, some cases may easily have been overlooked

The lack of spread of infection to the nurses was probably related to the relatively low infectivity at the stage of the disease at which the patients were admitted, and to strict measures for control of spread in the unit, including isolation in separate rooms during the period of presumed infectivity and the use of masks by nurses and ancillary personnel If, as is assumed, this disease follows infection of the respiratory tract, probably infectivity is limited to the first ten to fourteen days, as in most virus diseases, including poliomyelitis

Summary

From April 1 to Oct 31, 1955, 51 cases of confirmed poliomyelitis, of which 29 were non-paralytic, came under treatment During the same period 8 cases were observed in which the diagnosis was acute encephalomyelitis

The motor weakness, rigidity, exaggerated reflexes without muscular wasting, sensory disturbances, and normal cerebrospinal fluid suggested a disease other than poliomyelitis This was confirmed by serological tests for all three types of poliomyelitis virus

Electromyography showed absence of the denervation characteristic of poliomyelitis and the presence of long polyphasic units with reduced interference pattern characteristic of a myelopathic lesion In 1 case a repeat examination after five months showed no change

Persistent proneness to fatigue was a troublesome sequel in 6 cases

5 cases presenting behaviour changes were examined by electro encephalography Although abnormalities were detected in all the cases they were non specific and may be constitutional

5 of the 8 cases showed residual disabilities

Since this paper was completed, 3 additional mild cases have been admitted under our care

Our thanks are due to our colleague, Dr W St J Buckler, for the electrodiagnostic investigations and comment, Dr W A Cobb, of the electro encephalography department, National Hospital for Nervous Diseases, Queen Square, for recordings and comments and the director and staff of the Virus Reference Laboratory, Colindale for laboratory examinations and much helpful advice

FURTHER OUTBREAK OF A DISEASE RESEMBLING POLIOMYELITIS

D W SUMNER
B Sc , M B Manc
RESIDENT MEDICAL OFFICER, MANCHESTER ROYAL INFIRMARY
LATE MEDICAL SPECIALIST, R A M C

FROM time to time since 1948, outbreaks have been reported of an illness which in many respects resembles poliomyelitis, but which differs from poliomyelitis in its epidemiology, in the mildness of the illness itself, in the high proportion of normal cerebrospinal fluid (C S F) found, in the absence of any detectable virus and in the frequent psychological changes (Sigurdsson et al 1950, Pellew 1951, Acheson 1954, Macrae and Galpine 1954, White and Burtch 1954) I report here another such outbreak—a very small one—because it may help to establish the existence of a disease which has been graphically, if somewhat negatively named "not poliomyelitis" (*Lancet* 1954)

The patients in the present series were previously fit young soldiers, of whom all but 1 lived in the same barrack block in Berlin The 1 exception was an orderly who, having nursed the other patients, was himself a close contact Although the numbers involved were small—7 cases only—the disease was clear cut and the outbreak explosive, the last case being taken ill only eight days after the first

Clinical Features

The illness ran a fairly uniform course, starting with headache which was followed in most cases some three days later by pains in the limbs and back and commonly by photophobia The principal clinical features and laboratory findings are shown in the accompanying table, and the following case, representative of the series is described in some detail

Case 2 —The patient, aged 19, had been well until three days before admission when mild frontal headache developed while he was playing football This persisted, becoming very much worse and waking him from his sleep on the day of admission For two days he had noticed that bright lights hurt his eyes and for a day had had some aching in his shoulders By the time he was admitted, on Nov 15, 1954, his shoulder pain was quite severe and he had some pain in the right leg

On examination he was flushed and ill, with a temperature of 100 2°F No abnormality was to be found outside the central nervous system He was fully conscious with slight neck stiffness, but Kernig's sign was negative Photophobia was severe, and there was moderate conjunctival injection No nystagmus was detected, although upward gaze was painful No muscle weakness or wasting was to be found, but there was considerable tenderness of the trapezii, left lower intercostal muscles, right quadriceps, and left calf muscles There were no sensory changes, deep reflexes were brisk and equal, and plantar responses were flexor

Investigations —Lumbar puncture on the day of admission produced clear colourless C S F at a pressure of 180 mm of water, containing less than 2 cells per c mm and 40 mg of protein per 100 ml with no excess of globulin, the values for sugar and chloride were normal White blood cells in peripheral blood numbered 11,700 per c mm with a normal differential count No albumin was to be found in the urine

Progress —On the fourth day of his illness some slight weakness of the right trapezius and deltoid, and of the

R F READ

GIANT HYPERTROPHIC GASTRITIS

SIR,—Giant hypertrophic gastritis is so rare that few have the opportunity to treat many cases As stated by Dr Williams (April 7), gastrectomy is usually considered necessary when this condition gives rise to severe blood loss I have devised a less mutilating operation, and report here two cases in which it was undertaken

CASE 1—A woman aged 67, gave a history of many years' indigestion, worse for the past twelve months Her appetite had for this time been extremely poor, and she had lost a little weight On examination she was a frail old lady There was tenderness and a rather doubtful mass in the epigastrium Barium meal showed a filling defect in the mid zone, thought to be a carcinoma

Laparotomy was performed on Dec 11, 1952 The stomach, though it felt curiously thickened, was clearly not the site of a typical carcinoma The anterior wall was incised and immediately the gastric mucosa protruded, at first resembling a papilloma However, it was soon clear that it was a case of giant hypertrophic gastritis The mucosa could be lifted out of the opening without dimpling the muscle and serosal layers I was then faced with the question whether to perform a total gastrectomy The ease with which the mucosa could be lifted out of the stomach suggested that it might be possible to remove some of the redundant mucosa only To my delight, after incising the mucosa I was able to separate about 3 square inches from the muscularis Bleeding was slight and easily controlled without clamps Suture of the mucosa restored the continuity of the lining Recovery was uneventful and she remained well until the middle of 1955 She has at present symptoms similar to those of a gastric ulcer, but X ray examination shows only the enlarged mucosal folds Her appetite is not very good but she remains reasonably well on the medical regime used in peptic ulcer cases Re examination of the preoperative radiographs shows appearances typical of giant mucosal folds

CASE 2—A man, aged 30, had had severe, almost continuous epigastric pain for about twelve days, slightly better for the last two days He had vomited several times He had a past history of indigestion, with pain about an hour after food This had been investigated elsewhere, without a definite diagnosis being made On examination he was a sallow, anxious man There was no mass but some tenderness in the epigastrium Barium meal showed a filling defect on the greater curve but it was not typical of a carcinoma Gastroscopy showed no tumour but large folds, it was not realised, however, how large they were

Laparotomy was undertaken on March 3, 1953 The stomach was palpably thickened and felt somewhat like a bag of worms It was incised, and again the mucosa protruded like a papilloma I decided to follow the same course as in the previous case, and I removed 4–5 square inches of mucosa Bleeding was not severe and suture restored the lining satisfactorily He was followed up for over eighteen months and remained quite well although for some months he occasionally had indigestion He had had a great fear of cancer which had to be overcome Barium meal in May, 1953, showed hypertrophic folds but considerably less pronounced than before operation

On reflection I am sure I should have removed more mucosa in the first case I also think it would be quite easy to remove more mucosa than in case 2 This could perhaps be better done through two incisions Diagnosis should be easy before operation, as the radiographic appearances are so typical, but operation may still be undertaken to rule out a carcinoma Fortunately, if the diagnosis has not been made it will become obvious on laparotomy, especially if the stomach is opened Should the operation of mucosal resection fail, it could be repeated, or a total gastrectomy performed

Shenfield Essex

RESIN-REINFORCED PLASTER-CASTS

SIR,—I feel obliged to attempt to dampen the enthusiasm expressed by Mr Morrison (April 21) for the resin-reinforced bandages ('Gypsona-Extra')

Through the kindness of Messrs Smith & Nephew I had an opportunity to try these bandages when they were in the experimental stage, and my first reaction was one of enthusiasm Since the gypsona extra have come on the market for ordinary use I have used them exclusively in the sizes in which they are available My enthusiasm has by now considerably diminished

I agree that there is very little wasting of the plaster content I am not so convinced of the other advantages claimed for these plasters I have been particularly impressed by the fact that they take a long time to become quite rigid, compared with the ordinary gypsona bandages, in spite of the catalyst

I did not form this impression when I was using the experimental bandages on clinical trial, but I have observed this slowness particularly in the gypsona extra bandages now on the market This difficulty is overcome to some extent by squeezing the water out of the bandage very strongly, but it is not eliminated by this Between the moment of initial drying of the plaster and the development of complete rigidity there is a rather long phase in which the plaster appears hard but can be easily indented with moderate pressure of the hand Unless one is aware of the long duration of this phase there is a danger that the shape of the plaster may become distorted from the pressure of the surface on which it rests if it is not protected by suitable padding This long phase of plasticity has a further disadvantage if one is applying a plaster which has to be moulded on a limb It makes it difficult to mould the plaster accurately around bony points *When it is moulded in at one place it tends to bulge* out nearby like a rubber ball partly distended with air

Because of the slow drying of these plasters I have found it necessary to use for a cast a quantity of plaster not very much less than that used with ordinary gypsona The only alternative to this is to keep the patient a long time in the plaster room, because if the patient is transported back to the ward while the plaster is still in the plastic" stage there is a strong likelihood that the plaster will be spoilt

Though it is not a point of great importance, the finish of these plasters does not compare with the finish of the *ordinary gypsona plaster*

I would like once again to make a plea for the more universal use of the casts made out of a combination of 'Glassona' and ordinary gypsona By using a light base of gypsona on which the glassona can subsequently set slowly it is possible to make a very light cast for any region These casts are possessed of excellent rigidity so that, for instance, a spinal jacket can be split on one side and slipped off and put on again without losing its shape, and the forearm cast applied, say, for tenosynovitis can be split on one side and slipped off and reapplied and used in much the same way as a block leather support

I think it would be a great pity if either gypsona or glassona were taken off the market and replaced by the new gypsona-extra bandages

County Hospital Lincoln

DAVID F THOMAS

ADDICTION TO METHYLATED SPIRIT

SIR,—Many features described by Dr MacDougall and Mr MacAulay (April 21) were also present in methylated-spirit drinkers among alcoholics admitted to Warlingham Park Hospital in recent years—for instance, "emotional blunting, a tendency to vagrancy, pessimism, and depression" As Dr MacDougall says, quite a few methylated spirit drinkers can be rehabilitated The proportion of-methylated spirit drinkers was somewhat higher among our alcoholic patients (varying over the years from 10 to 20%) and there were several women among them, including one with optic atrophy The average age at which these people began to take methylated-spirit was 35 6 years (i e, in the "chronic phase" of alcohol addiction), after having consumed excessive an epidemic of Bornholm disease in Oxford, Warin et al (1953) found only 8% of cases with neither abdominal nor chest pain and only 8% with limb pains In addition, the inability to isolate the Coxsackie virus did not support such diagnosis

Leptospirosis was excluded on epidemiological grounds, by the negative agglutination tests, and by the absence of jaundice or albuminuria Moreover, in this series vomiting was slight, but it must be admitted that the conjunctival injection and limb tenderness were reminiscent of leptospiral infection

That the outbreak was of a single disease entity must, I think, be accepted because of its restricted nature and the consistent clinical picture with regard to both symptoms and physical signs That it was the disorder described as "Iceland fever" by White and Burtch (1954) and as "not poliomyelitis" by *The Lancet* (1954) is suggested by the following features

(1) The limited nature of the outbreak In this respect the present series is very similar to those described by Macrae and Galpine (1954) and by Acheson (1954) in nurses' homes

(2) The extreme muscle tenderness with neither paralysis nor reflex changes

(3) The high proportion of cases with normal C S F

(4) The mild, but persistent, mental changes, and the persistent headache, were particularly striking features The mental changes seen in other outbreaks were stressed by Macrae and Galpine (1954) and by Pellew (1951)

Two features of the outbreak described by Pellew (1951) were seen here one was hyperacusis, of which 2 patients complained, the other was recrudescence of the symptoms after several days, which was most noticeable in case 4 who had extreme muscle pain and tenderness The conjunctival injection in 5 of the 7 cases has not been described in any outbreaks While no reflex changes or persistent weakness occurred, objective evidence of neurological involvement was afforded by the presence of nystagmus in 5 cases—a common finding in the outbreak described by Acheson (1954) The transitory erythematous rash seen in 2 patients has not been described elsewhere

Future work may show that the group of outbreaks reviewed in *The Lancet* (1954) are not a homogeneous group, and indeed, cases described by Acheson (1954) with prominent neurological signs may differ from the milder cases described by Sigurdsson et al (1950) and White and Burtch (1954), which the present series more nearly resembles For the purpose of prognosis, it is well to recognise this group of infections with their explosive epidemiology, since the outlook is so much better than in true poliomyelitis

Summary

In November, 1954, there was an explosive, but limited, outbreak of a disease resembling poliomyelitis, affecting 7 soldiers in Berlin

The syndrome was marked by headache, limb pains, and muscle tenderness, photophobia and hyperacusis were common, and in some cases headache and depression persisted in convalescence

The C S F was normal in every case but 1 No virus was detected, and agglutination tests were negative

CLINICAL FINDINGS SIX YEARS AFTER OUTBREAK OF AKUREYRI DISEASE

BJORN SIGURDSSON
Dr med Iceland
DIRECTOR, INSTITUTE FOR EXPERIMENTAL PATHOLOGY, UNIVERSITY OF ICELAND, REYKJAVÍK

KJARTAN R GUDMUNDSSON
Laeknir, Iceland
CLINICAL NEUROLOGIST, REYKJAVIK

In 1948–49 there was an extensive epidemic of 465 cases simulating poliomyelitis in the town of Akureyri in northern Iceland (Sigurdsson et al 1950) The population of Akureyri being 6900 the attack rate was 6 7% Paresis was observed in 129 cases There were no deaths The attack-rate was highest in the age group 15–19 but was also high among young adults generally There were very few cases in children aged less than 5 years

The disease was accompanied by low pyrexia, which sometimes persisted for weeks, and by pains in one or more limbs and in the nape and back Muscle tenderness, often restricted to small areas, was also a prominent symptom The aches often persisted long after the disappearance of all objective signs Disturbances of sensation were not infrequently observed, and complaints of nervous instability, sleeplessness, and loss of memory persisted in many cases for a long time afterwards

Fæces were tested for poliomyelitis virus and for Coxsackie virus, but no virus was found

Since 1950 several outbreaks have been described which very much resemble Akureyri disease (Pellew 1951, Acheson 1954, Macrae and Galpine 1954, White and Burtch 1954, Gear 1955) The symptoms and epidemiological behaviour of these infections are hardly sufficiently characteristic to enable all these various outbreaks to be classified together before information on their specific cause is obtained However, it seems very likely that these epidemics constitute a nosological entity, but the relationship, if any, to poliomyelitis remains obscure Several workers besides ourselves have attempted to isolate an infective agent from this type of case, but nobody seems to have succeeded so far

The protracted and even relapsing nature of the infection was one of the features which distinguished it rather clearly from poliomyelitis In numerous instances vague but annoying symptoms persisted a long time after the infection was presumably over

This prompted a renewed study of some of the patients examined in 1949

Material and Method

One of us (K R G) went to Akureyri in June, 1955, and subjected 39 previous patients to a complete neurological examination Only patients who had been examined shortly after the outbreak six years ago were examined this time All the former patients except 1 with gastric ulcer were back at their usual work There were 33 females and 6 males The attack rate during the epidemic was higher in females (8 3%) than in males (5 1%)

Results

Table I summarises the results of the clinical examination It will be seen that only 12 of the 39 patients (31%) were free from objective clinical signs, and only 5 patients (13%) considered themselves completely recovered

Table II shows how frequently the various signs and symptoms were found six years after the patients fell ill In 1949 several of the patients were neurotic and showed functional symptoms This was still the case in June, 1955, but only those symptoms which seemed to be organic have been included in the tables as he fell many times on this short journey There has been no change in his electro encephalograph, which shows a typical spike and wave pattern

CASE 2 —An imbecile girl, aged 12 years, had had very frequent petit-mal attacks since admission The attacks were not so severe as in case 1 and it was impossible to record their frequency accurately Her walking was very unsteady although she did not often fall No drugs had proved very beneficial and the best regimen seemed to be primidone 0 25 g thrice daily and dexamphetamine 2 5 mg twice daily To this was added mepacrine and since then the frequency of her attacks has been reduced and she walks much more steadily

Arellano and Alejandro stated that a period of excitation occurred a few days after the course of mepacrine, but neither of these patients showed this I hope that others will try this apparently safe therapy

Chertsey Surrey

GORDON DUTTON

RADCLIFFE RESPIRATION PUMPS

SIR,—We are much interested in the description of the Radcliffe respiration pumps by Dr Ritchie Russell and his colleagues in your issue of April 28

They state that the use of a free dropping weight is the best method known to them of producing a positive pressure wave, because it removes the need for a safety-valve and gives a "square" (and therefore maximally shortened) pressure-wave Avoidance of the need to fit a pressure limiting device does not, in our view, make much difference, since a weight-operated safety-valve, for example, is simple and reliable The square form of positive-pressure wave is not limited to weight-operated pumps but can be obtained with lever operation and a cam-operated valve timed to allow a build-up of pressure before opening

There are obvious limits to what can be done by shortening the positive-pressure wave to keep mean intrathoracic pressure at a low level, and Maloney et al[1] found that respirators of the intermittent positive-pressure type did not compare favourably in their circulatory effects with those having a negative-pressure phase We can see, however, that a square curve with an abrupt flow of tidal air is useful in ensuring early opening of a pressure operated valve such as the Stott or the Smith-Clarke,[2] although this advantage disappears if a mechanical valve is used

It may turn out that negative pressure in expiration is of crucial value only in an occasional case and that its effect does not bulk large in a series, especially as the Oxford workers have had good results without it We are interested to see that the latest modification of the Radcliffe pump recognises a potential value in negative pressure by following the Smith-Clarke positive-negative respirator[3] in providing for its employment as well as by fitting a cam operated mechanical inspiratory/expiratory valve—which we believe appreciably increases the safety of intratracheal pressure respiration

REVISION OF THE CURRICULUM

SIR,—In answer to Dr Walker (April 28) it may not be generally known that a tutorial system similar to that envisaged by him is in existence in the clinical school at Oxford

An individual attachment to a tutor has long been an integral and valued part of the preclinical course here When the clinical school was opened it was decided to extend this system of personal tuition into the years the student spends in hospital The practice is to attach each student to a member of the staff the period of attachment varies, but during the course of his training he receives individual tuition in turn from a physician, a surgeon, and an obstetrician The form which this tuition takes is left to the tutor concerned It may be discussion of current research, essays on selected subjects, or more systematic instruction in a field of medicine in which the student is known to be weak

We believe that these tutorials form a valuable part of the curriculum in that they are one of the surest ways of stimulating discussion between pupil and teacher, and of fostering the student's interest in the advancement of medicine

Director of Clinical Studies

HOME CONFINEMENT

SIR,—I feel that I must reply to some of the things that Professor Russell says in his paper last week He quotes me as saying that the home is the right place for a confinement What I have consistently said is, that producing a family is the essence of making a home, and it is reasonable to expect a normal and physiological process to occur there, provided that the home is fit for a confinement to take place there and of course that the case is a normal one

My real point in writing this letter is, however, to agree with Professor Russell that it is high time for the maternity services to be rationalised and coordinated—our difficulty may be in agreeing how the coordination should occur From my experience we may find that some at least of the difficulties lie at the door of the teaching hospitals Allowing for their special position, it is not unreasonable to expect them to take their quota of social cases, and to become real partners in a coördinated midwifery scheme, we must not forget that the general practitioner has an important part to play

I think, however, that it is an excellent thing that we should have an exchange of ideas, and a desire to improve upon a standard of midwifery that has probably never been better While welcoming the setting up of the committee to consider the midwifery service, it is perhaps unfortunate that there appears to be little representation from the local-authority side which has been responsible in the past for the over-all supervision of the midwifery in its area

Sheffield

LLYWELYN ROBERTS

ADMINISTRATION OF IRON IN ANTENATAL CLINICS

SIR,—Dr Edgar and Dr Rice state (May 5) that they were compelled to use tabellæ ferri sulphatis as there was no suitable alternative and at the time of planning the trial ferrous gluconate was not available This would appear to date their work back by some four or five years

A more recent development in oral iron therapy has been provided by ferrous succinate ('Ferromyn'), which I have shown[1] to evoke a satisfactory clinical response in the treatment of iron-deficiency anæmia due to pregnancy. With administration of one tablet three times a day 105 mg of bivalent iron is made available for hæmopoiesis, and this small dose rarely causes any intolerance 52 patients with severe hypochromic anæmia due to excessive demands for iron in pregnancy were given this daily dose and all responded, the average mean daily hæmoglobin rise being 1% (0 148 g per 100 ml)

These results compare favourably with those of Dr Edgar and Dr Rice using the ferrous sulphate salt, 5 4% of their patients being excluded from the investiga-

TABLE I—ADMISSIONS AND DEATHS FROM INFECTIONS OF LOWER RESPIRATORY TRACT IN CHILDREN AGED LESS THAN 2 YEARS IN 1953 AND 1954

Diagnosis	Admissions		Deaths	
Staphylococcal pneumonia				
Certain	21 (*4%*)	35 (*6 5%*)	4 (*16 5%*)	8 (*33%*)
Probable	8 (*1 5%*)		0	
Complicated	6 (*1%*)		4 (*16 5%*)	
Other pneumonias	53 (*10%*)		8 (*33%*)	
Other infections of respiratory tract				
Bronchitis Bronchiolitis	442 (*83 5%*)		8 (*33%*)	
Total	530		24	

We review here the cases in which *Staph aureus* was isolated and contrast them with the others admitted in the same period

Reasons for Lung Puncture

Staphylococcal pneumonia used to be diagnosed mainly at necropsy (Macgregor 1936), it was diagnosed in life only on aspiration of an empyema

Kanof et al (1939, 1953), Campbell et al (1954), and Wallman et al (1955) have built up a picture of the clinical and radiographic features of staphylococcal pneumonia, but their cases were, for the most part, either complicated by empyema or not proved bacteriologically if the infants recovered before an empyema was formed

Cultures from the upper respiratory tract are uninformative because of the high carriage rate in healthy persons, and blood culture is rarely positive in primary staphylococcal pneumonia (Kanof et al 1939)

In view of the histological findings of Reimann (1933) and Gibson and Belcher (1951) that large numbers of staphylococci are present in the early stages of staphylococcal pneumonia it was reasonable to hope that lung puncture might yield information about the infecting organism, and thus allow earlier diagnosis and treatment Moreover the propensity of the staphylococcus to develop resistance to antibiotics might make the isolation of the organism and the determination of its sensitivity important to the treatment

Material

530 infants, aged less than 2 years, were admitted in 1953 and 1954 with infections of the lower respiratory tract and were diagnosed variously as having bronchitis, bronchiolitis, bronchopneumonia, and pneumonia (including virus and neonatal) Of these 530 infants 88 had radiographic signs of pneumonia, and 35 we diagno as having staphylococcal pneumonia (table I)

Although staphylococcal pneumonia accounted for only a small percentage of the admissions in the age group with infections of the lower respiratory tract it accounted for nearly half of those with radiographic evidence of pneumonia and for a third of the deaths from infection of the lower respiratory tract

In view of the difficulty of being certain of the diagnosis in each case of staphylococcal pneumonia and to facilitate description the cases have been divided into three groups as follows

(1) *Certain staphylococcal pneumonia* —These 21 cases are considered proved for the following reasons 17 had both clinical and radiographic signs of either pneumonia or fluid together with the isolation of *Staph aureus* from either pleural pus or lung juice, and in 4 fatal cases *Staph aureus* was cultured from the lung at necropsy

(2) *Probable staphylococcal pneumonia* —These 8 cases did not present the fully developed clinical picture of 5 infants in whom *Staph aureus* was obtained by lung puncture and culture, 4 presented atypical clinical appearances, and the remaining 1 cleared unusually rapidly, 1 infant in whom lung puncture proved negative on admission had a typical clinical course and responded typically to treatment, and in the remaining 2 cases no lung puncture was done, the diagnosis depending in 1 of them on typical pneumatocele formation seen on radiography, and in the other on a staphylococcal osteitis of the maxilla draining pus into the mouth When pneumonia of the right lower lobe developed in this infant two days later it was considered to be due to inhalation of staphylococcal pus from the mouth We therefore believe that all those 8 cases were probably staphylococcal pneumonia, most of them being earlier and milder than usual

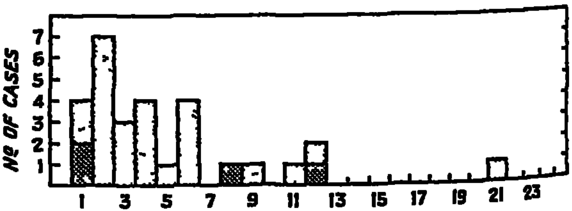

Fig 1—Age-distribution of staphylococcal pneumonia of infants Fatal cases are shown by hatching

(3) *Complicated staphylococcal pneumonia* —These 6 cases were secondary to serious underlying disease, and are not considered further here, because they did not present the usual picture 3 had fibrocystic disease of the pancreas, 1 congenital heart disease, 1 renal insufficiency, and 1 a muscular dystrophy These 6 had the highest mortality (4 deaths)

Clinical Features of Staphylococcal Pneumonia

To obtain an over all picture of staphylococcal pneumonia in infants we have studied the certain cases and the probable cases as representing a fair sample They are considered together in table II Although the inclusion of the probable cases is subject to criticism their omission would be even more misleading because the early stages of staphylococcal pneumonia would not then be fairly represented

Fig 1 shows the age distribution and confirms the high mortality in the first few weeks of life

The usual picture was of a toxic infant, with grey cyanosis and respiratory distress The hallmark of established staphylococcal pneumonia on clinical examination was obvious signs of either consolidation or fluid in the chest, this was present in 24 of 29 cases, whereas in the other 53 radiographically diagnosed pneumonias it was noted only in 7 In most cases there was an antecedent infection of the upper respiratory tract This, considered with our findings of an increased incidence during the winter months (fig 2) in step with the more numerous admissions of infants with infections of the lower respiratory tract, bears out the view that

TABLE II—CLINICAL PICTURE OF STAPHYLOCOCCAL PNEUMONIA IN INFANTS

—	Certain	Probable	Total
No of cases	21	8	29
Age	2 wk –21 mos	5 wk –6 mos	2 wk –21 mos
Onset			
Preceded by infection of upper respiratory tract	16	4	20
Acute or fulminating	4	1	5
Pyrexia > 100°F on admission	13	4	17
Signs of pneumonia	19	5	24
Leucocytosis > 18,000 per c mm	9/16	1/5	10/21
Radiography on admission			
Opaque lung field (empyema)	4	0	4
Pneumatocele without empyema	6	3	9
Pleuritis	5	1	6
Non specific infiltration	3	4	7
Not radiographed	3	0	3
Free empyema	7	0	7
Deaths	4	0	4

Only about 10% of the households presented special difficulties of the problem-family type and the opportunity was taken to attempt some improvements in their way of life The remaining 90% were helped to the mutual advantage of both the family and the county council. This valuable service seems likely to expand

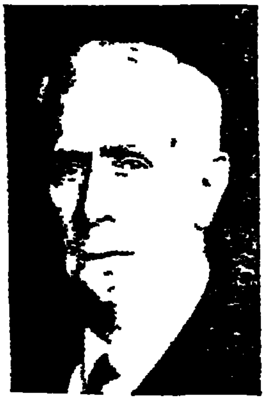
---

Obituary

SHELDON FRANCIS DUDLEY

K.C.B O.B.E., M.D Lond LL.D Edin F.R.C.P F.R.S

Sheldon Dudley was born in the Royal Naval sick-quarters at Lisbon in 1884 the son of Deputy Inspector-General John Dudley He grew up in an age when sons, especially Service sons followed in their father's footsteps, and he passed directly into the Royal Navy from St Thomas's on qualifying in 1906 His life reflects the opportunities and limitations of the Naval Medical Service He spent, as he once said twelve years at sea as a general practitioner and practised as a part-time specialist in six subjects, winning distinction in all and for his research on immunology election to the fellowship of the Royal Society.



[illegible]

When the 1914–18 war broke out, with service in Mediterranean and China stations already behind him, he was acting as pathologist and venereologist at the R.N. hospital at Chatham. During the war he also served as P.M.O of the R.N. Air Service in Dunkirk and of H.M.H.S. *Agadir* After the war he became pathologist at Haslar and at the R.N. Medical School Greenwich Here his research on the immunology of diphtheria was begun Of these years H J P writes:

"I was greatly privileged to know Sheldon Dudley during the most fruitful period of his research career when he was grappling with the control of diphtheria at the Royal Hospital School, Greenwich, and developing a practical and philosophic interest in epidemiology With a changing population of 1000 boys there had been no fewer than 385 cases of diphtheria between 1919 and 1927 mostly concentrated into two major epidemics At that time artificial immunisation had not been started and Dudley was able to use the material for initiating his well known studies of herd immunity

"An immunisation scheme for the school was authorised somewhat tardily in 1928, and resulted in the almost complete disappearance of clinically recognisable diphtheria Dudley's success at Greenwich and the observations made concurrently in fever hospitals and elsewhere that diphtheria could be virtually abolished even when exposure might be constant and intense undoubtedly influenced the authorities in their decision to introduce the national immunisation campaign in 1940

"Bacteriologist statistician immunologist and epidemiologist Dudley was of outstanding intelligence and originality of mind A keen and persistent investigator he used to good purpose the basic immunological knowledge derived from the laboratory experimentation of A. T Glenny I found it very stimulating to listen to his penetrating and practical survey of current problems Pertinent questions were always being asked, and he had plenty of new ideas, none of which proved to be a bad one in retrospect—an exceptional achievement Opportunities for further research were seldom wasted and his notes were always kept so carefully and accurately that analysis of his data was relatively easy His capacity for putting his finger on essential details undoubtedly served him well when he later shouldered heavy administrative responsibilities"

In 1930 after a further spell of service at sea, he was promoted surgeon captain and returned to Greenwich as director of medical studies and naval hygiene at the medical school In 1935 he was appointed M.D.G and three years later medical officer in charge of the R.N. Hospitals at Chatham. After 1941 his appointment as medical director-general in years of strenuous warfare filled his days with administration to the exclusion of research and clinical medicine Of this inevitable but frustrating separation and of its effect on Surgeon Vice-Admiral Dudley's last years a colleague writes:

"As a research-worker Dudley possessed outstanding gifts—vision scrupulous honesty, a capacity for taking infinite pains, and a comprehensive grasp of a problem These qualities were happily revealed while he was medical officer in charge of the Royal Naval Medical School at Greenwich in 1930–32 when his work on immunisation against diphtheria was carried out For this research he used the boys at the Royal Hospital School then occupying the buildings which now house the National Maritime Museum and it was from his study of the results of the Schick test that he developed his theory of herd immunity His approach was impersonal: the boys were a perfectly controlled sample of the human herd and a sick-berth staff dormitory in a naval hospital or a room at a Royal Naval barracks were ideal media in which to test his views on the spread of droplet infection It was natural for him to enjoy working among statistics and in their interpretation he showed the full power of his mind This was never more brilliantly expressed than in his Milroy lectures of 1931 on the distribution of infectious diseases in the Royal Navy, in the preparation of which he analysed and reinterpreted all the returns made in the *Health of the Navy* since the inception of this blue-book. This work led to a close association with the late Major Greenwood and to Dudley's election to the fellowships of the Royal College of Physicians and the Royal Society

"As a Gilbert Blane medallist Dudley was singled out for promotion which inevitably but unfortunately removed him from research to administration When he was appointed medical director general in 1941 he had to assume a heavy burden at a critical period It was lightened for him only by the interest he felt in the many research problems created by the need for protection from new weapons or in new conditions But he could not give this interest free rein and while his representatives on the Medical Research Council's committees occupied his chosen province he himself was bound to administrative work.

"When 1944 came and he was due to retire the end of the war was in sight and it was felt unwise to change horses in midstream and so he continued in office to the end. Perhaps the strain had been greater than he or anyone else had realised and when he was free at last to return to research he appeared unable to summon the energy Instead he became medical officer in charge of the Royal Naval Hospital at Bermuda thus coming to serve as a surgeon captain in the island where the former director-general of the Army Medical Services was to become governor He held the office for nearly two years and then entered on a final retirement from which he emerged only with the publication of two books—*The Four Pillars of Wisdom* and *Our National Ill-Health Service*"

R C M adds

"I had known Sir Sheldon very many years, but did not fully appreciate his great attributes and virtues until I had the pleasure and privilege of serving with him in the Medical Department, Admiralty during the turbulent years of World War II He was rather reserved and it was difficult for strangers to break the ice, but once that was done there was revealed a kindly humble honest, and very human being

"His main interest in life was highly scientific epidemiology, embracing bacteriology and allied science I could not help but feel that he placed medical administration on a much lower level than his epidemiology! His outlook was philosophical in its widest sense

"However in spite of his essentially professional make up he was always very helpful in administrative matters He remained calm when chaos reigned and always gave a sound lucid and logical decision under trying circumstances. His sense of humour never left him, and it was very profitable indeed to listen to him expounding some immunological or other theory during a convivial evening in a medical mess.

"During his active career he reinstated the Naval Medical Service in the medical world, and those of us who knew him will always remember his friendly smile His advice was always encouraging and of great value His wisdom was prodigious"

Results

24 infants recovered completely, 1 is left with bronchiectasis, and 4 died

Recoveries (24)

In nearly half the infants who recovered, the pneumonia i in a relapsing course It was here that the duration of treatment came into question It seemed that a comparison of the duration of the initial treatment of those who relapsed with that of those who made an uneventful recovery might help to decide the optimal length of treatment It was possible to assess 19 infants 11 recovered uneventfully after eighteen days' treatment, whereas the 8 who relapsed had an average of only eleven days' initial treatment The following case provides the most salutary warning, there being two relapses

A baby boy, aged 3 months, was admitted with three days' history of anorexia, snuffly nose, and cough

On examination he had a temperature of 99 2°F, nasal discharge, and signs of pneumonia at the right base Radiography showed consolidation and pneumatocele formation On thoracic puncture a small blob of pus appeared, and this grew penicillin resistant *Staph aureus*

Treatment —The baby was treated with erythromycin for twelve days at the end of which his chest seemed clearer both clinically and radiologically Eleven days after the end of this course of treatment his cough returned, he lost weight, his temperature rose to 99 6°F, and the signs at the right base became more obvious Lung puncture was repeated, and this time no pus was obtained, but the juice again grew penicillin resistant *Staph aureus* After eighteen days' further treatment with erythromycin the baby still had signs at one base, so, after three days' interruption, treatment was continued for another fortnight, by which time the clinical signs had almost disappeared, the white cell count had fallen from 15,600 to 9300 per c mm, and the chest on radiography was nearly clear

The reasons which led us to relatively short treatment were, inter alia, the rapid clinical response, the apparent well-being of the infants, and the consciousness of using wide spectrum antibiotics with their particular dangers to infants The necessity for prolonged treatment to prevent relapse in deep seated staphylococcal infection has long been recognised and is emphasised by Kirby et al (1953) and Neligan (1955) Both the relapsed cases and the uncomplicated recoveries seem to show that at least from twenty one to twenty-eight days' treatment with appropriate antibiotics, whether singly or in pairs, is indicated The radiographic change persisted so long (average three months) that the advice of Kanof et al (1953) to continue treatment until the chest is radiographically clear could not have been followed in many cases When a relapse took place, the warning signs were anorexia and lack of weight-gain, followed later by leucocytosis and pyrexia

Bronchiectasis (1)

This infant did not present the usual clinical picture of staphylococcal pneumonia on admission, having wide spread crepitations without signs of consolidation It was only after a lack of response to ten days' treatment with penicillin followed by eleven days' treatment with chlortetracycline that a lung puncture was done in an area where clinical and radiographic consolidation had appeared The strain of *Staph aureus* recovered from his lung was sensitive to erythromycin only He responded initially to this antibiotic, but we stopped treatment after eight days, not realising then the necessity for prolonged antibiotic cover He relapsed and did not clear completely on a second and longer course of erythromycin

Deaths (4)

The 4 deaths (mortality 14%) took place at the ages of 1 month 7 weeks 8 months, and 1 year 3 infants died within a few hours of admission and before any antibiotic could have taken effect They could have been saved only by earlier diagnosis and treatment The f infant was aged 1 month and had an overwhelmi infection but survived five days despite profoun polymorph leucopenia

TABLE IV—DIFFERENTIAL DIAGNOSIS

Other pneumonia	53	7	0	1	[illegible]	[illegible]
Other infections of lower respiratory tract	442	0	0	0	2	[illegible]

* Thoracic puncture was mainly restricted to infants suspected having bacterial pneumonia

As Wallman et al (1955) point out, the mortality i still about 50% in the first month of life

Antecedent Staphylococcal Infection

In view of the high staphylococcal carriage rate in th noses, eyes, and umbilical stumps of neonates, and th concern over the treatment of minor infections in ver young infants (Forfar et al 1955), we tried to discov any such incidents in our series The results were follows

Of 18 infants born in hospital 15 were not known to hav had any infection, 1 had had ophthalmia neonatorum at th age of 5 or 6 days and was admitted with staphylococca pneumonia at the age of 16 days, 1 had had a stye at the age 7–10 days and was admitted with staphylococcal pneumo at the age of 4 weeks, and the mother of 1 admitted wi staphylococcal pneumonia at the age of 14 weeks had had breast abscess on the seventh day after delivery There w no history of neonatal infection in 5 infants born at home, a in 6 infants the facts are not known

The numbers are small, but, since 23 of the 29 infant were aged 6 months or less, and 14 were aged 3 month or less, the small number with a positive history of overt infection suggests that other factors, such as nasal carriage, are more important (Court et al 1955), at lea so far as staphylococcal pneumonia is concerned

The main problem, as Barber and Burston (1955 suggest, is to discover what makes the staphylococcu become invasive In the present series it looks as if a antecedent virus infection is the most likely factor in view of the seasonal incidence and the history (table II)

Discussion

The deaths and the history of antecedent infection o the upper respiratory tract in many cases show that we have much to learn about when the picture change from a respiratory infection of presumed virus origin to the usually more severe staphylococcal invasion, which demands more urgent and specific treatment In our series the history did not seem to differ much from that of dozens of children admitted with other respiratory disease The main differences were found on clinical examination, radiography, and lung puncture The results are summarised in table IV

If our findings are representative and the probable cases are accepted as true cases, any infant aged le than 2 years with clinical signs of pneumonia or of fluid ha more than three chances to one of being infected with *Staph aureus*

The radiographic findings of empyema or of pneumatocele appear to be pathognomonic

The radiographic evidence of pleuritis or of localised pleural exudate in 6 infants on admission confirms the general belief of early involvement of the pleura This pleural involvement without free empyema wa case was carried steadily and purposefully to its proper conclusion He seldom spoke about his surgical work, the more's the pity that we shall not hear his Bradshaw lecture which was to be given this year Though shy and somewhat ill at ease on the platform, he was a most effective speaker in committee, where he never said an unnecessary word when he spoke he did so with wisdom and to the purpose, sometimes even trenchantly, for his character displayed a nice blend of firmness with quiet and somewhat reserved friendliness As a chairman he had no superior, hardly a peer Business was conducted with expedition and yet every member was heard, younger members of the staff of his hospital were thankful to find a chairman prepared to give attention and consideration to their views His actions and judgments were tempered by a strong sense of fairness and justice he was thus able to contribute in no small measure to the happy relation existing between his hospital and the university At the Royal College of Surgeons, as in his hospital, his gifts as a counsellor soon became evident But it will be as a private counsellor (his advice was often sought on personal matters) that he will be remembered by many, as a raconteur who would enliven his colleagues with stories culled from his experience and told with his especial brand of humour and charm and as a friend"

Mr Scott Mason leaves a widow, Dr Helen Fox, the anæsthetist and two sons and a daughter

HYACINTH BERNARD WENCESLAUS MORGAN

M D Glasg

Dr H B Morgan, who died at his home in London on May 7 was for the last fifteen years one of the small band of medical members of Parliament He was also medical adviser and consultant specialist on industrial disease to the Trades Union Congress, and many of his contributions to parliamentary debates reflected his interest in industrial medicine and his wide experience of its problems

[Daily Herald

He was born in Grenada in the West Indies and obtained much of his education through his own efforts He won a scholarship at the Grenada grammar school and after working as a civil servant there he saved a little money and came to this country to study medicine At Glasgow University with the help of scholarships and bursaries, he managed to complete his course and in 1909 he graduated M B The same year he won the Scottish inter-university McCunn research scholarship Soon afterwards, he came to London and held house-appointments at several hospitals, including Great Ormond Street In 1914 he obtained his M.D with commendation and also took the D P H

During the 1914–18 war he served as a surgical specialist at Horton War Hospital After he was demobilised he settled in practice at Greenwich and also for some years held a part-time appointment under the Ministry of Pensions As a student in Glasgow he had become interested in politics He now turned to them again and stood as a Labour candidate for the London County Council in Greenwich in 1922 and again in 1925 Later, after he moved his practice to Camberwell, he stood unsuccessfully for North-West Camberwell in several parliamentary elections He was finally elected in 1929, only to be unseated in 1931 He did not return to the House of Commons until 1940 but after that he sat continuously until he retired last year He represented in turn Rochdale and Warrington

His last years in private practice, before he retired in 1931, were spent in Paddington He also held several consulting posts with trade unions, including the Union of Post Office Workers, and these led to his appointment as medical adviser to the T U C He was a consulting physician to the Manor House Hospital and he held the Louis Starling lectureship on industrial diseases

Dr Barnett Stross, M P, writes

"For many years before I was elected to serve in Parliament I knew Dr Morgan I had heard him lecture on industrial disease and on many occasions corresponded with him He was the most approachable of men and always delighted to help a colleague with advice and give assistance from his own varied and wide knowledge On the subject of the injured or diseased worker he was a zealot and an enthusiast Every case he advised on was to him a living issue He saw the social background and suffering of those who were deprived of their means of livelihood almost as a personal problem He struggled against injustice as if it were always directed against his own person When he showed suspicion and intolerance of authority it was because he was ever watchful on behalf of those whom authority might oppress

"I never knew him speak slightingly in private conversation of any one in the House He combined a most redoubtable capacity for public controversy with personal charm Every one liked him and those who knew him longest miss him most"

In 1930 Dr Morgan married Miss Mary Powell who survives him with two daughters

Q fever, and lymphocytic choriomeningitis, as well as titrations of streptococcus M.G. agglutinins and heterophil antibodies.

There was clinical or radiographic evidence of pulmonary consolidation in 42 cases and evidence of inflammation of the lower respiratory tract without consolidation in 28. Serological studies revealed that 17 patients had influenza A, and the virus was isolated from the lungs of 2 other patients. There were significantly raised titres in the complement-fixation test for influenza B in 3 cases, psittacosis L.G.I. group in 3, and Q fever in 2. The streptococcus M.G. and cold agglutinins were raised in 4. Not less than an eightfold rise in titre was considered significant in these serological tests.

Sputum obtained on admission of the patients to hospital gave rich growth of *Streptococcus pneumoniæ* in 8, *Strep. pyogenes* in 6, *Escherichia coli* in 8, *Hæmophilus influenzæ* in 3, *Klebsiella pneumoniæ* in 1, *Mycobacterium tuberculosis* in 2, and coagulase-positive *Staph. aureus* in 4.

The 4 cases with coagulase-positive *Staph. aureus* in the sputum were admitted in the middle of an influenza A epidemic in the first quarter of 1953. The organism was present in very large numbers, and in 3 cases it was grown in pure culture. All 4 patients were extremely ill, and 2 of them died. A brief description of these cases follows.

INFLUENZA COMPLICATED BY SECONDARY STAPHYLOCOCCAL INFECTION

Case 1.—A housewife, aged 53, was admitted to hospital with the diagnosis of bilateral bronchopneumonia after four days' increasing chest pain and dyspnœa. Despite oxygen, penicillin, and aureomycin her condition deteriorated rapidly, and she died within twelve hours of admission. *Staph. aureus* was isolated in pure rich culture from her sputum. The organisms were sensitive to penicillin, chloramphenicol, aureomycin, and streptomycin. Influenza-A virus was isolated from the lungs post mortem.

Case 2.—A draughtsman, aged 63, who had had chronic bronchitis for six years was admitted to hospital with three weeks' history of increased breathlessness and cough. Clinical examination suggested diffuse bronchopneumonia, which was confirmed by chest radiographs showing patchy consolidation of the upper lobes and a cystic pattern over the rest of the lung fields. The patient improved rapidly on general therapy. *Staph. aureus* was isolated in rich culture from the sputum along with a scanty growth of hæmolytic streptococci. Complement-fixation tests for influenza A showed on admission a titre of 1/64, which remained constant for two weeks. Seven months later the titre for influenza A was less than 1/8.

Case 3.—A man, aged 72, who had had chronic bronchitis for many years, was admitted gravely ill with extreme dyspnœa and cyanosis. Clinically there were signs of bronchopneumonia throughout his lungs. Despite treatment with oxygen, penicillin, and digoxin he died within eighteen hours of admission. *Staph. aureus* was grown in pure rich culture from his sputum. His white-cell count was 86,000 per c.mm. (neutrophil polymorphs 42.5%, neutrophil metamyelocytes 21.5%, neutrophil myelocytes 17.5%). A complement-fixation test for influenza A showed a titre of 1/512. Attempts to isolate influenza virus from lung tissue post mortem failed.

Case 4.—A woman, aged 80, was admitted to hospital with a week's history of acute respiratory infection. Examination showed diffuse bronchopneumonia, particularly in the lung bases. Extreme weakness, cyanosis, and dyspnœa persisted for four days, after which improvement was steady. *Staph. aureus* was isolated in profuse growth from her sputum. Complement-fixation tests for influenza A on the first, sixth, nineteenth, and thirty-seventh hospital days and seven months later showed titres of 1/16, 1/128, 1/128, 1/64, and less than 1/8 respectively.

OTHER CASES WITH STAPHYLOCOCCI IN SPUTUM

During the year under review 9 other patients were found to have a coagulase-positive *Staph. aureus* in one or more specimens of sputum but not on admission. None of these patients had influenza, and none was in hospital during the epidemic period.

In 6 of these patients the growth of staphylococci was scanty and took place in solitary specimens when the patients were recovering satisfactorily from a lung infection or had recovered completely. For these reasons little meaning can be attached to the presence of the staphylococci. From the sputum of the remaining 3 patients *Staph. aureus* was isolated more than once. 2 of these patients had lung tumours, and the 3rd was a chronic bronchitic aged 64.

The clinical and bacteriological evidence therefore favoured the view that the staphylococci found in the cases of influenza were producing a severe disease, whereas those found in other cases were not. Special serological tests described below produced further evidence in favour of this conclusion.

Antibody Studies

During the 1951 influenza A epidemic our attention was directed to post-mortem findings on 2 patients who had died with fulminating pneumonia after a very brief illness. The stained films of pus from the trachea and lungs of both these patients were so rich in staphylococci that they resembled the smear of an actual colony. *Staph. aureus* was isolated in pure culture from both patients. Unfortunately no attempt was made to determine the presence of influenza virus.

This rapidly fatal illness in previously healthy persons and the ubiquity and profusion of the cocci in the lungs suggested that the local tissue and humoral antibody defences had been overwhelmed. We thought it would be profitable to investigate the circulating antibodies to *Staph. aureus* during such an infection. This was done on the sera from the patients in our series with acute infection of the lower respiratory tract, from healthy persons, from patients with minor staphylococcal lesions, and from 6 patients with severe non-pulmonary staphylococcal infections.

The antibody to the α-lysin of the staphylococcus was chosen as the most convenient index of the humoral antibody level. Not only do virulent strains of *Staph. aureus* produce α-lysin but also the titration of this lysin and its antibody is technically precise and relatively simple.

TABLE I—LEVELS OF STAPHYLOCOCCAL α-ANTITOXIN IN HEALTHY PERSONS, PATIENTS WITH INFECTION OF LOWER RESPIRATORY TRACT, AND PATIENTS WITH NON-PULMONARY STAPHYLOCOCCAL LESIONS

Serum antitoxin levels (I.U. per ml.)	Influenzal pneumonia				Non-influenzal infection of lower respiratory tract				Healthy persons	Patients with minor skin lesions	Severe non-pulmonary staphylococcal lesions

without sulphur or elemental sulphur could be obtained from gypsum , but in either case, he says, it would be necessary to consume an extra amount of coal about equal to the weight of sulphur produced or replaced The fixation of atmospheric nitrogen by the bacteria of leguminous plants is possible only if there is also an ample supply of phosphorus, calcium, magnesium, and sulphur, and the artificial fixation of atmospheric nitrogen by man depends on the use of coal both as a source of energy (though there it can presumably be replaced by nuclear fission) and for chemical reasons So far, " the consumption of wasting assets has merely been shifted from nitrate to coal" about 5 tons of coal being needed to fix 1 ton of atmospheric nitrogen Further, the more nitrogenous fertiliser is used the greater is the demand for alkaline earths Therefore the more factories we build for making such fertiliser, the more lime and other earthy base we must supply not merely to neutralise the resultant acidification of the soil, but also for incorporation in the additional crops—the target of all this effort Nicol tells us that 18½ million tons of fertilisers will have to be provided to every 1 million tons of nitrogen produced synthetically from the air Any extension of food production will therefore depend on further chemical, engineering, and industrial effort leading to additional consumption of fuels and other wasting assets Fuel, he remarks, "is as essential to food production on a present day scale as it is to the continued existence of air lines"

At the end of all this endéavour, we must also take account of the tendency of the soil towards homœostasis In Nicol's words "Whatever man does towards raising the level of organic matter and available nitrogen in the soil, his efforts at striking a higher balance will be resisted and opposed by the soil microbes and other natural agencies These agencies will coöperate to destroy and remove any unnatural excess of organic matter and to restore the proportion of organic matter to what is natural to the soil" Even when, in the ordinary course of affairs, the nitrifying bacteria of the soil convert ammonia or ammonium salts into nitric acid, a demand for alkalis is set up to neutralise the acidity, which is inimical to both the bacteria and the plants Apart from supplying such alkalis there is no point in "feeding" the soil bacteria, which constitute a very finely balanced system Increase in the supply of any one material merely throws the system out of equilibrium The same principle applies to artificially irrigated land (including deserts) the natural equilibrium has been upset, and the price must be paid either in fuel or by going without the crops Though, by sufficient effort, the desert can be made to blossom as a rose, we cannot expect much return from its cultivation unless we have the fuel to make fertilisers for it, to irrigate and drain it, and to distribute the food it grows

A DAY HOSPITAL

A DAY hospital and treatment centre for 30 patients has been opened at Whitchurch Hospital, Glam The former bakery and tailor and bootmaker's shops of the hospital have been converted by the maintenance staff into a two storeyed building On the ground floor there is a waiting-room and records room, accommodation for the visiting E N T surgeon, dentist, and chiropodist and a group therapy room with seating for 50 patients On the first floor there are three consulting rooms, a medical library, and a room for the clinical clerks Patients will attend the hospital from 9 A M to 5 P M and will return to their own homes each evening They will be selected from those attending psychiatric outpatient clinics and from among the convalescent hospital inpatients who are ready to return home but who still need to continue their treatment Dr T J Hennelly, the superintendent, describes the new venture as providing treatment at the hospital rather than in the hospital

---

University of Oxford

Dr R M Bannerman has been elected to a Radcliffe travelling fellowship

University of London

On March 21 the degree of M S was conferred on C Naunton Morgan and R J H Smith

University of Glasgow

On April 30 the degree of PH D in medicine was conferred in absentia on Ian Macadam, B SC

Royal College of Surgeons of England

At a meeting of the council on May 10, with Sir Harry Platt, the president, in the chair, Mr A Lawrence Abel was elected vice president in place of the late Mr Scott Mason Dr Bernard Johnson (Middlesex Hospital) and Prof M Lucas Keene (Royal Free) were admitted to the fellowship, having been elected as medical practitioners of twenty years' standing Mr David Trevor (Charing Cross) was admitted to the court of examiners Mr Lawrence Abel was appointed Bradshaw lecturer for 1956

The Cartwright prize for 1951–55 was presented to Mr B E D Cooke and a certificate of honourable mention to Mr N L Rowe The Robert Jones travelling fellowship was awarded to Mr Michael Alms The Gilbert Blane medal for 1956 was awarded to Surgeon Commander J M Holford, the Mitchiner medal to Lieut Colonel R E Waterston, and the Lady Cade medal to Air Commodore C A Rumball The Begley prize was awarded to C R N Ashbee (St Bartholomew's Hospital Medical School)

Postgraduate diplomas and diplomas of membership were conferred on the candidates named in the report of the comitia of the Royal College of Physicians (*Lancet*, May 5, 1956, p 644)

Royal College of Surgeons of Edinburgh

At a meeting of the college held on May 9, with Sir Walter Mercer, the president, in the chair, the following were admitted to the fellowship

P L Berger, John Bingham A C Bowring M E J Brightman, Ivan Coll, Harold Collinson, G I B da Costa G A Dalton Prakash Chandra Dubey, D B Eaton, A W Eklund C A Ezike C L Greaves, M B Johnson, E P J King R P Leake J I de Boer Leembruggen D O Maisels, N K G Mendis J H Miller A H Mizrachy, Hari Mohan James Morgan Nuggihalli Ranganath Aiyengar Narayan K G Orr J R Page Hyman Perkin Kamalesh Pandurang Prabhu Mohammad Abdul Qayyum, L A Sarembock, F W Shea C A Shearer D M Sinclair, Dhurandhar Prasad Singh R D Smith B D Stringer J N Tennant, I C K Tough, Robert Yule

University College of the West Indies

The University of London has taken this university into a special relation by which students of the college work for degrees of the university, the examinations for the degrees being held in Jamaica under the supervision of examiners appointed by the university Students who pass obtain a full degree of the University of London as external students Holders of the M B , B S degrees obtained in this way are entitled, on application, to registration by the General Medical Council The following have been successful

Dorrit V M Box, L M Burke C J Charles D E Christian, R I Forbes H R Francis B A Q Hamilton Smith K A W McKenzie O D O Minott D B Mitchell Pamela E B Rodgers, A R Walwyn M O Woo Ming (October 1954) Betty Millbourne Clark (April 1955) L B Bannister T E Been R K Berry, F N Boland G B P Cummins Barbara E Johnson S S Lutchman, Myrtle E Mitchell, D I M Picou Premchand Narpat Ratan N L Read R O Saunders K L Standard K M W Tang Norma C M Theobalds (October 1955)

London College of Osteopathy

The Leverhulme Trust Fund is providing scholarships to enable qualified medical men and women to study osteopathy at this college They will cover the cost of fees and maintenance The course begins next October, and application should be made before June 30 Particulars may be had from the secretary of the college, 24, Dorset Square, London, N W 1

Royal Northern Hospital, London

This hospital is celebrating its centenary from June 25 to 30 this year The programme includes medical and surgical demonstrations at the hospital and a dinner at the Royal College of Surgeons on June 26, which the Duke of Gloucester will attend

Royal Medical Benevolent Fund

The annual general meeting of this Fund will be held on Tuesday, June 5, at 5 P M , at 11, Chandos Street, London, W 1, with Lord Webb Johnson, the president, in the chair

Hunterian Society

The subject for the gold medal essay of 1956 is the Care of the Growing Child in General Practice The competition is open to all doctors in general practice Further details may be had from the hon secretary of the society, Mr R S Murley, 95, Harley Street, London, W 1

COMBINED SURGICAL AND PHYSICAL TREATMENT OF SUPERFICIAL SEPSIS

Philippe Bauwens
M R C P
PHYSICIAN IN CHARGE, DEPARTMENT OF PHYSICAL MEDICINE

M G Cox
M A, M B Camb, F R C S
SURGICAL REGISTRAR

Anthony B Coyer
M B Durh, D Phys Med
SENIOR REGISTRAR, DEPARTMENT OF PHYSICAL MEDICINE

ST THOMAS'S HOSPITAL, LONDON

The casualty department at St Thomas's Hospital has a close liaison with the department of physical medicine, which provides treatment by physical methods in minor sepsis This has shortened the patient's period of incapacity, compared with routine surgical treatment alone The time saving is of great economic importance since the majority of such patients are wage earners

Stimulated by the high incidence of superficial sepsis and septic wounds, particularly of the hands, during the war years in London, one of us started using a section of the physical medicine department for the treatment of these conditions (Bauwens 1940) He worked in conjunction with the resident assistant surgeon and his staff, who performed the necessary surgery

A similar organisation exists at present, staffed by trained physiotherapists who apply all dressings and use various physical treatments These include local heating by means of short-wave diathermy, infrared radiation, or micro waves, which result in increased circulation and the activation of defensive processes in the affected area, and ultraviolet radiation, again usually applied locally with the aid of the Kromayer lamp, the therapeutic effect of which results from destructive action on bacteria and increased rate of proliferation of tissue cells (Bauwens 1950) Occasionally ultrasonics are found to be of value in early cicatrisation, especially in the case of ulcers, where thickening and scarring of adjacent skin delay full healing (Curwen 1953)

In the lower limbs, sepsis, laceration, and ulceration are commonly complicated by œdema which retards healing Such conditions are greatly improved by the application of strong elastic bandaging, first advocated by Bisgaard (1948) and later developed by Curwen and Scott (1952)

The effects of treatment are of course greatly enhanced by complete rest of the parts directly or indirectly involved Thus many cases of sepsis of the upper limb digits, hand, or forearm are helped by temporary splinting with Kramer wire and the use of a sling, in the initial stages At the same time, in order to prevent stiffness, the immobilised joints are put through a full range of active movements at each attendance

The routine treatment of carbuncles includes shaving and cleansing the surrounding skin with surgical spirit and applying a counter-irritant dose of ultraviolet light After this, it is swabbed with a 1 in 1000 solution of biniodide of mercury in acetone The skin is then immobilised with elastic adhesive bandage, leaving a window over the pointing area of the carbuncle This allows purulent matter to discharge freely and prevents its contact with the neighbouring skin and infection of surrounding hair follicles Short-wave treatment is applied twice daily followed by occasional E 4 doses of ultraviolet rays when the slough separates Dry dressings are applied regularly over the exposed part of the carbuncle

As an indication of the value of this combined surgical and physical treatment compared with surgical treatment alone, one type of lesion—paronychia of the hand digits—was singled out for investigation The condition was sufficiently prevalent to provide significant numbers for both experiment and control, and allowed of easy objective assessment

Method

One of us (M G C) for a period of six months saw all the cases of acute paronychia of hand digits in the hand clinic of the casualty department Patients who were suspected of having pus under the base of the nail were treated by wedge incisions of the nail-bed angles combined with total nail removal under digital block anæsthesia (Rodney Smith 1954)

Immediately postoperatively the nail-bed was dressed with tulle gras and covered with gauze and wool, and the arm was placed in a sling Each patient was inspected the following day by M G C and referred for treatment to the department of physical medicine Here, treatment consisting of short wave diathermy heating was applied twice daily for periods of about ten minutes, starting about twenty-four hours after the initial operation Local applications of ultraviolet radiation in E 3 and E 4 doses were given by means of the Kromayer lamp every other day Where infection was severe, the open area was dusted with 2% aureomycin in K 28 starch powder Sterile tulle gras dressings were reapplied daily The patients were discharged by one of us (M G C) when the surface was dry and the patient considered fit for work without a dressing 118 patients over 14 years of age, and 23 children aged 13 years or less, were treated by this combined routine

As a control series, 33 consecutive patients aged 14 years or more were submitted to the surgical routine already described without receiving any physical treatment They were re dressed the following day with 1 in 1000 solution of proflavine hemisulphate and thereafter seen at intervals of two to three days when similar dressings were applied until the wound had healed and the patient was fit for work

Cases of acute paronychia complicated by adenitis or lymphangitis were not included in this investigation since they were given, concurrently, systemic antibiotic therapy

Results

30 patients over 14 years of age (group A) treated by combined surgery and physical methods alone were discharged after an average time of 4·3 days

88 patients over 14 years of age (group B) with more severe sepsis, necessitating the local application of starch powder containing 2% aureomycin, treated by combined surgery and physical methods were discharged after an average time of 5·3 days

23 children aged 13 or less (group C) treated by combined surgery, physical methods, and local application of starch powder containing 2% aureomycin were discharged after an average of 4·1 days

ENCEPHALOMYELITIS SIMULATING POLIOMYELITIS

A MELVIN RAMSAY
M A, M D Aberd
PHYSICIAN

E O'SULLIVAN
M D Dublin
SENIOR REGISTRAR

INFECTIOUS DISEASES DEPARTMENT,
ROYAL FREE HOSPITAL, HAMPSTEAD, LONDON

IN the summer of 1955 cases of encephalomyelitis simulating poliomyelitis appeared in North-West London The general picture and the results of investigation, however, have shown that a diagnosis of poliomyelitis is untenable, pareses unaccompanied by wasting, tendon reflexes generally unaffected or exaggerated, sensory disturbances, normal cerebrospinal fluid, and electromyographic studies which fail to reveal any evidence of neuronal degeneration indicate a different ætiology and pathology Similar outbreaks have been reported from Adelaide (Pellew 1951), Coventry (Macrae and Galpine 1954), New York (White and Burtch 1954), London (Acheson 1954), and Durban (Cheetham, personal communication) The obscure infection responsible for an epidemic among the nurses of the Royal Free Hospital, Gray's Inn Road (see *Lancet* 1955), was probably of a similar nature It is probable that the outbreak in Iceland in 1948 (Sigurdsson et al 1950) was an aberrant form of poliomyelitis, as the spinal fluid proved abnormal in every instance in which it was examined

We describe here 8 cases, variously notified as meningitis, poliomyelitis, and pyrexia of unknown origin, which occurred between April 1 and Oct 31, 1955 During that period 51 patients with confirmed poliomyelitis (22 paralytic, 29 non-paralytic), slightly more than the yearly average since 1947, were admitted to the Infectious Diseases Unit at this hospital They were aged 9–45 years and were all female except 1, aged 27 1 belonged to the non resident staff of a London teaching hospital, where one or two similar cases occurred among the nurses, and another had been an inpatient at a neighbouring hospital None of the patients had been in contact with each other or, so far as could be ascertained, with cases of the current infection among the nurses at Gray's Inn Road These cases were notified to the medical officers of health of the various boroughs in which they resided as acute infective encephalitis, in accordance with the regulations in force from Jan 1, 1950

Clinical and Other Features

CLINICAL PICTURE

The onset was generally insidious, with various initial symptoms Headache, pains in the limbs, and giddiness were prominent in most cases Lassitude and inertia (drowsiness in 3 cases), nuchal pain, symptoms of infection of the upper respiratory tract with sore throat, vomiting, paræsthesiæ, anorexia, and nausea, were present in over half the cases Muscular cramps, twitchings, pain referred to the ears, and transient or persistent tinnitus were also noted On admission lymphadenopathy affecting chiefly the posterior cervical lymph nodes was found in 7 cases various grades of neck stiffness, paresis, and exaggerated reflexes in 6, objective sensory impairment and muscle tenderness in 5, cranial-nerve involvement in 4, extensor plantar responses in 3, nystagmus in 2, and diplopia in 1 The left side of the body, especially the left lower limb, was mainly affected In 1 patient mild hepatitis developed and was confirmed by liver function tests, it was impossible to say whether this was part of the disease, the result of giving chlorpromazine, or an independent infective or serum hepatitis Pyrexia did not usually exceed 100°F and tended to recur transiently with relapse of symptoms The stay in hospital lasted from nineteen to ninety-four days Recovery was slow, and convalescence protracted, with mental and physical fatigue and emotional instability in half the cases 3 cases show persistent weakness and sensory impairment four to six months after the onset

BLOOD PICTURE

In all the cases the blood picture was characteristic of a virus infection—i e, neutropenia with inconstant abnormal lymphocytes The term "abnormal lymphocyte" is somewhat loose but means here the next stage to the abnormal mononuclear cells characteristic of "glandular fever," no instance of which was encountered in this series Blood smears taken from cases of poliomyelitis, febrile catarrh, and the present infection were submitted to several experienced hæmatologists, who were unable to detect any distinguishing feature which could assist the differential diagnosis

CEREBROSPINAL FLUID

The cerebrospinal fluid was normal in every case except 1 in which the protein level was 50 mg per 100 ml, a repeat examination after thirteen days in 1 case was still normal The Wassermann and Kahn reactions were negative

VIRUS INVESTIGATIONS

Despite intensive investigations, in collaboration with the Virus Reference Laboratory, Colindale, an ætiological agent has not been isolated Throat washings and/or fæces were examined in tissue culture of monkey kidney for poliomyelitis and Coxsackie and other viruses Screening by serological testing of paired sera for lymphocytic choriomeningitis, mumps, leptospirosis, and all three immunological types of poliomyelitis was negative in each case

ELECTROMYOGRAPHY

All 8 cases exhibited muscle weakness and were submitted to electrodiagnostic examinations Usually the weak muscles showed abnormalities of motor unit activity revealed by the electromyographic pattern, but in no instance was evidence of lower motor neurone degeneration detected Thus nerve conduction was retained, muscle responses were brisk to direct long duration stimuli (100 msec), and intensity duration curves showed rheobases within normal limits and threshold intensities for 1 msec stimuli less than twice the rheobase Electromyographic exploration of the muscles showed no spontaneous activity, in particular no fibrillation potentials, but on volition the number of motor unit potentials was reduced (reduced interference pattern) with a tendency to occur in groups of up to 6 potentials,

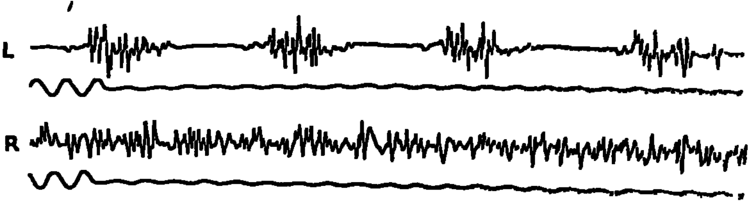

Fig 1—Electromyographs from case 1: *upper register, from left tibialis anterior muscle on maximal volition, showing grouping of large polyphasic motor unit potentials; lower register, from right tibialis anterior muscle on maximal volition, showing complete interference pattern of normal motor unit potentials.* (Calibration 500 and 100 µV at 50 cycles per sec)

6926

acute episodes. Ultimately there was no response to bigger doses, and she died after 3 years' treatment. The diagnosis was confirmed at necropsy.

Chronic Bronchitis

CASE B.—A housewife, aged 41, with increasingly severe bronchitis for 18 years, each intercurrent infection causing many weeks of great incapacity, showed an excellent response to oxytetracycline, with greatly reduced cough and dyspnœa. Her sputum, which had amounted to 4 oz. daily, was reduced to $^{1}/_{4}$–1 oz.; she felt much better generally and gained 8 lb. in weight. Upper respiratory infections rarely necessitated bed rest or caused much incapacity. She remains greatly improved, having continued the treatment for $2^{1}/_{2}$ years with doses varying from 1 to 3 g. daily. *Hæmophilus influenzæ* was last recovered from her sputum after $1^{1}/_{2}$ years' treatment when it remained sensitive to oxytetracycline. The sputum now persistently contains *Proteus vulgaris*, which seems to have no adverse effect on the patient's condition.

CASE C.—A policeman, aged 51, with increasingly severe bronchitis for 5 years was admitted to hospital extremely ill and in heart failure. He made a dramatic recovery on oxytetracycline and was able to return to duty for 2 years and thus to qualify for his pension. He has been less breathless, and his sputum has been reduced from 2 oz. to less than 1 oz. daily. His general condition has remained much improved, and his weight is 2 stone greater than before treatment. He has had one period of 3 weeks in bed following an upper respiratory infection, but his general improvement has been maintained for $2^{3}/_{4}$ years to the present time on continued oxytetracycline, the dose varying from 1 to 3 g. daily. *H. influenzæ* has been obtained intermittently from his sputum, and on the last occasion, after $2^{1}/_{4}$ years' treatment, it remained sensitive to the antibiotic.

Seven other patients were still receiving oxytetracycline at the time of the last report (Helm et al. 1954). Treatment was discontinued in four of these for the reasons set out in the accompanying table. In two of the other three patients improvement has been maintained up to the present time.

One, who was originally admitted to hospital acutely ill with heart failure, has had two further but less severe episodes of failure while administration of the antibiotic has been continued for $2^{1}/_{2}$ years. Although his improvement has been least distinct of all in this group he has been able to lead a normal quiet retired life, and his condition has deteriorated when attempts have been made to stop treatment. His sputum has remained reduced from 2 oz. to 1 oz. daily, and *H. influenzæ* was last isolated from it after a year's treatment, when the organism remained sensitive to oxytetracycline.

RESULTS OF TREATMENT OF THIRTY-EIGHT PATIENTS WITH OXYTETRACYCLINE

Diagnosis	No.	No. remaining on treatment at time of last report (1954)	No. remaining on treatment with benefit to present time	Reason for abandoning treatment in others
Chronic staphylococcal bronchopneumonia	1	1 (30 mos.)	0	Died after 3 years' treatment
Bronchitis	17	9 (7–20 mos.)	5 ($1^{1}/_{2}$–$2^{3}/_{4}$ yr.)	2 patients responded well but treatment was stopped in order to obtain an autogenous vaccine. 1 patient responded well but had recurrent diarrhœa and treatment ultimately had to be stopped. 1 patient had relatively slight benefit and treatment was therefore stopped
Infective asthma	13	0		
Bronchiectasis	7	4 (6–8 mos.)	3 ($1^{1}/_{2}$ yr.)	1 patient had relatively slight benefit and treatment was stopped
Total	38	14	8	

Another patient, also admitted in heart failure, has continued to take 0·5 g. of oxytetracycline twice daily for 20 months. His sputum volume was reduced early from 4 oz. to 2 oz. daily, and it has remained consistently at this level. It has been mucoid since the first week of treatment and *H. influenzæ* has not been found since then. This patient feels very well generally, but he is compelled to lead a sedentary life owing to the breathlessness resulting from his severe emphysema.

The third patient still receiving oxytetracycline responded well initially to 1 g. three times a day. His sputum, previously mucopurulent for years, became mucoid within a week, and its volume was reduced from 3 oz. to 1 oz. daily. He continued satisfactorily for 9 months on a maintenance dose of 0·5 g. twice daily, but unfortunately the treatment was inadvertently stopped at this time. Within a fortnight pus had returned to the sputum, the daily volume of which rose to 2–3 oz. Oxytetracycline therapy was restarted, but, although he has improved again to some extent, he has never regained the condition he had reached before the treatment was stopped. His sputum is still mucopurulent and amounts to about 3 oz. daily after a further 10 months' treatment. It contains many *H. influenzæ*, which are resistant to oxytetracycline.

Bronchiectasis

Four patients with bronchiectasis were continuing treatment at the time of the last report (Helm et al. 1954). In one the benefit was relatively slight, and oxytetracycline was stopped with the object of substituting treatment with an autogenous vaccine. The other three have maintained their improvement in a remarkable way to the present time. All had up to 4 oz. daily of mucopurulent sputum, which has been reduced to 1 oz. or less and is mucoid in each case. All patients have gained weight.

One, a schoolmistress, is especially glad to have greatly reduced cough and sputum. She had an attack of asthma—the first for years—soon after starting oxytetracycline but this responded to routine treatment and there has been no recurrence. *H. influenzæ* was isolated once during treatment (after 10 months) from this patient's sputum, but sensitivity tests were not carried out.

No pus or *H. influenzæ* have been found in the sputum of either of the other two patients at any time since treatment began. One persistently harbours *Pseudomonas pyocyanea*, which apparently has no adverse effect on the patient. Both have less breathlessness, and one maintains that she has "not felt so well for 20 years."

TOXIC EFFECTS

Diarrhœa has been the only side-effect encountered, but in only one patient was it so severe that oxytetracycline had to be discontinued. Liver-function tests have been carried out on five patients, but in each they have remained normal. These findings have been confirmed in other patients treated in the same way but not included in the present series. One of these died in heart failure after a year's treatment with oxytetracycline. At necropsy there were changes in the liver typical of congestive cardiac failure but no evidence of any toxic effect of the antibiotic.

Discussion

At the beginning of this investigation (Helm et al. 1954) thirty-eight patients were started on oxytetracycline therapy (one with chronic staphylococcal bronchopneumonia, seventeen with chronic bronchitis, thirteen with infective asthma, seven with bronchiectasis). Of these eleven of the asthmatics were considered not to have a true infection, so twenty-seven infected patients remained. A good early response to oxytetracycline was obtained in twenty-four patients, but for various reasons plantar response was flexor, and a left plantar response could not be elicited. A week later the patient complained of pain in the left side of her face and neck, next day lower right facial palsy was noted and paresis of the left foot increased. After a further week pain of pleural type developed in her left chest but clinical and radiographic examination was negative. By the end of August her general condition had improved and complaints of pain were infrequent, but the signs in the central nervous system were virtually unchanged. On getting up, although her sense of balance was normal and Romberg sign negative, she walked on a wide base with a tabetic type of stamping gait. Graduated exercises effected slow but steady improvement.

Follow up.—On Nov. 22 she had returned to work, but she complained of undue fatigue toward the end of the day. Weakness affecting her right lower face, left arm, and left leg and sensory loss in her left leg were still present. On Dec. 14 there was general improvement but still much weakness and sensory loss in her left leg, with right lower facial weakness.

Case 3.—An unmarried female domestic worker, aged 20, developed malaise and giddiness on Aug. 11, followed by headache, faintness and lassitude, on Aug. 15. She was admitted to the unit next day.

On admission her temperature was 99.4°F, and she appeared to be mentally dull but well oriented. Slight neck rigidity was present, but Kernig's sign was negative. There was slight impairment of muscle power in the flexors and extensors of her right knee. Her deep reflexes were within normal limits, abdominal reflexes present, and plantar responses flexor. She had a coarse tremor of her head and arms, especially on sitting up. A few small glands were palpable in the posterior cervical region.

Subsequent Course.—Her temperature settled within twenty-four hours of admission and, except for a rise to 99.4°F on Aug. 30, the patient remained apyrexial. Neck rigidity increased considerably and persisted for four days. Bilateral palsy of her external recti muscles was noted on Aug. 22, and her knee-jerks became exaggerated. Tremulous movements of her head and arms persisted and were aggravated by movement or by sitting or standing. The patient became emotionally unsettled and discharged herself on Sept. 4. During a period spent subsequently at a convalescent home she complained of further attacks of giddiness and was readily fatigued and notably lacking in energy.

Case 4.—A married housewife, aged 40, developed occipital headache, severe giddiness, vomiting and pains in her nape and limbs on Aug. 18, 1955, all symptoms were aggravated by movement and usually relieved by recumbency.

On admission to the unit on Aug. 20 her temperature was 99°F, and she was anxious sweating, moderately flushed and exhibiting much tremor of her arms. Some neck rigidity was present, but Kernig's sign was negative. She had slight generalised muscle weakness, her deep reflexes were within normal limits, abdominal reflexes absent, and plantar responses flexor. No sensory impairment was detected.

Subsequent Course.—The illness was characterised by intermittent bouts of low grade pyrexia. Shortly after admission the patient complained of pains and paræsthesiæ in her legs of sufficient severity to interfere with sleep. On Aug. 21 weakness appeared in her left leg with increase of subjective phenomena without demonstrable sensory loss. This was followed two days later by tremulousness of the right lower part of her face and by left lower facial weakness with left hemiparesis and hemianalgesia, the latter was maximal distally. The deep reflexes were diminished in her left arm, but her knee and ankle jerks became exaggerated. Her right plantar response was extensor, her left could not be elicited. Bouts of vomiting inertia giddiness, and tinnitus came on irregularly, usually coinciding with low grade pyrexia. When the patient got up, her gait was uncoördinated and her giddiness increased. On Oct. 4 mild hepatitis developed, and thereafter the patient became emotionally unstable and discharged herself on Oct. 18.

Follow up.—On Dec. 9 her general condition showed definite improvement, she was steady on her feet, and her gait had obviously improved, but she still complained of nausea, flatulence, and persistent tinnitus in her left ear. She had slight weakness of dorsiflexion of her left foot, but otherwise her muscle power was normal, and all evidence of sensory loss had disappeared, although considerable tremor of her hands persisted.

Case 5.—A male instrument maker, aged 27, had coryza during the first week of August and complained of sore throat from Aug. 12 to 15. On Aug. 17 he developed numbness of the right side of his face, loss of taste over the right side of his tongue, and repeated attacks of vomiting and giddiness. He could not retain fluids during the next ten days and was admitted to the unit on Aug. 27.

On admission his temperature was 99.8°F and he looked extremely ill, toxic, and dehydrated. A sparse maculopapular rash was present on the front and back of his thorax. Nystagmus was present on lateral deviation to either side but coarser to the left. Sensation to fine touch was completely absent over the distribution of the right 5th cranial nerve, there was hyperæsthesia to pinprick over the same area, temperature sensation was normal. He had mild paresis of the right side of his face, and his tongue on protrusion deviated to the right. Taste sensation was absent over the whole of the right side of his tongue. His deep reflexes were exaggerated, abdominal reflexes present, and plantar responses flexor.

Subsequent Course.—Occasional peaks of pyrexia not exceeding 100°F occurred throughout his illness. Vomiting continued for two days after admission. Dehydration and electrolyte balances were corrected with intravenous fluid therapy. Sensation began to return to normal after ten days, at the same time his facial paresis steadily abated. On Sept. 16 his plantar responses had become extensor, and he had a fine tremor of his arms and legs, slightly more exaggerated tendon reflexes on the right side, and slight facial paresis on the left. Impairment of his sense of balance and occasional attacks of giddiness were noted when the patient was allowed to get up, but otherwise his convalescence was uninterrupted and progressive. The sense of taste is still absent from the right side of his tongue, but in other respects his recovery is now complete.

Case 6.—A female professional dancer aged 28, had coryza from Sept. 14. Two weeks later she developed sore throat and acute vertigo lasting two or three hours. On Sept. 30 she had abnormal sensations, including numbness in both legs, especially the left.

On admission she was apyrexial, with no meningism although full neck flexion caused discomfort in her neck muscles. Power, tone, and deep reflexes were normal in her arms. Her abdominal reflexes were present. She had diminished power in both legs especially the left, her deep reflexes were within normal limits, and both plantar responses were flexor. There was an area of impaired tactile sensation around her left knee joint. A few shotty glands were palpable in the left posterior cervical triangle.

Subsequent Course.—The patient remained apyrexial throughout her stay in hospital. The hypo-algesia and hypo-æsthesia of her left leg increased for a few days after admission and involved the limb up to the mid thigh. Joint sense and vibration sense were also impaired over her left leg. On Oct. 5 rotatory nystagmus was noted, and the patient complained of diplopia on looking directly upwards, there was no evidence of ophthalmoplegia. When she got up, her rigid gait resembled that found in poliomyelitis with spasm, but her deep reflexes were exaggerated.

Follow-up.—Proneness to fatigue persisted, but otherwise the patient appeared well.

Case 7.—A girl, aged 15, had coryza intermittent headache, and weakness in her right leg on Oct. 1 1955. A week later her leg felt numb and afterwards became painful on movement.

On admission to the unit on Oct. 10 she was apyrexial, and she remained so throughout her stay in hospital. Slight neck rigidity was present. No abnormality was noted in either her cranial nerves or her arms. Her abdominal reflexes were absent on the left side, and she had weakness of the extensors and flexors of her right knee joint and the plantar flexors of her right foot. An area of sensory loss was present over the medial aspect of her right calf. Her leg reflexes were equal but exaggerated, her plantar responses were flexor. Apart from slight faucial injection and a few small glands in the left posterior cervical triangle there were no other abnormal findings.

Subsequent Course.—All the muscles in her right leg became weaker, and her right gluteus maximus muscle was found to be affected. Paresis was greatest in the plantar and dorsiflexors of the ankle. Sensory loss and motor weakness were present throughout the patient's stay in hospital. She was discharged on Nov. 1.

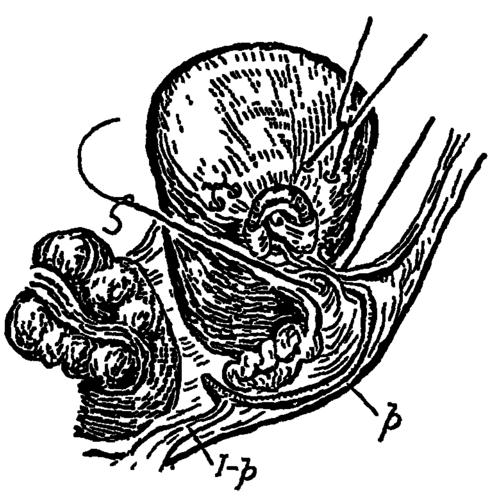

Fig 3—Polyethylene cord passed into uterus through peritoneal lined opening. p, polyethylene cord; I p, infundibulo pelvic ligament.

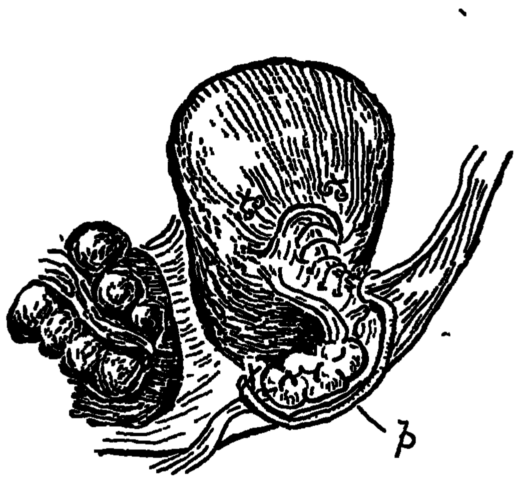

Fig 4—Polyethylene cord enclosed in peritoneal channel by continuous suture over round ligament. p, polyethylene cord.

the uterine wall (fig. 2). The cornu of the other side is reamed and peritonised in the same way. Polyethylene cord 2 mm. in diameter is passed into the uterine cavity through the artificial aperture (fig. 3). The free ends of the polyethylene cord are sutured to the infundibulo pelvic ligament near the ovaries. A peritoneal channel is made around the polyethylene cord on each side, where it emerges from the uterine aperture, for 3–4 cm. by a suture of continuous 00 chromic catgut; in this way the round ligament is oversewn by a fold of broad ligament to enclose the polyethylene cord (fig. 4).

Where an ovary has previously been removed the operation is done on one side only, and the uterine end of the polyethylene cord is brought through the cervix. The polyethylene cord is left in situ for 90 days. The patient is given vitamin C 200 mg. t.d.s. for 6 weeks before the operation and antibiotics cover for 90 days afterwards.

Discussion

Surgical methods for treating occlusion of the uterine tube have been reviewed and discussed by Siegler and Hellman (1956) and Greenhill (1956). The methods used have been mainly either partial reconstructive plastic techniques (Szendi 1953, Jarvinen 1954) or tubo uterine implantation (Green Armytage 1952). More recently transplantation methods have been tried, with either amniotic membrane (Ten Berge and Tik Lok 1954) or, experimentally in dogs, segments of vein or artery (Davids and Bellwin 1954). Foreign material—e.g., polyethylene tubing and membrane—have also been used (Mulligan et al. 1953).

There are some objections to the use of transplantation methods mainly because of tissue reactions; to some extent the same objection might be raised in the case of foreign substances such as polyethylene. There exist also the uncertain effects of such synthetic materials in the special circumstances of fertilisation and cleavage in the uterine tube.

The present operation, which has been devised to circumvent these difficulties, is based on the fact that the ovarian germinal epithelium and the peritoneum both have their origin in the cœlomic epithelium of the young embryo (the uterine tube also is closely related developmentally to the cœlomic epithelium since it arises by infolding of this membrane). Therefore there is a rational basis for reconstructing a uterine tube from peritoneal epithelium.

Oversewing the round ligament into the wall of the reconstructed tube is designed to assist the transport of the ovum which is mainly effected by the activity of the uterus. Together with the uterine tube, the uterus and round ligaments undergo contraction at ovulation, and it is presumed that, at this time and at subsequent fertilisation, muscular contractions of these structures continue whether or not the uterine tube is present. The lack of cilia in the reconstructed tube is of lesser importance since the uterine tube is normally incompletely ciliated; transportation of the ovum is almost certainly effected normally by muscular activity of the tube and uterus.

Where less extensive reconstruction is required, the same principle could be applied by a simple modification of technique. So far partial reconstruction according to this principle has not been described.

Summary

A total plastic reconstruction of the uterine tube from local peritoneal tissue is described, and the theoretical basis for the operation is outlined.

The operation consists of oversewing the round ligament with broad ligament peritoneum over a former of polyethylene cord; a new interstitial section and uterine ostium are reamed and lined by uterine peritoneum.

Four operations have been done using this technique.

Where complete replacement of the tube is not required a simple modification using the same principle may be tried.

AREA PATHOLOGIST

AREA LABORATORY, WHIPPS CROSS HOSPITAL, LONDON

NUMEROUS histological classifications of bronchial carcinoma have been suggested. These have often been based upon absurdly few cases, but Barnard (1938) and Bryson and Spencer (1951) classified a large amount of necropsy material.

At this laboratory we have for the past four years classified lung cancer in the manner described by Walter and Pryce (1955) and find this to be satisfactory from the point of view of the histologist, but during an investigation into the possible relationships between blood groups and cancer it became obvious that a more precise technique of classification was needed.

Most workers recognise three types of lung cancer—the oat cell, the squamous cell, and the *adenocarcinoma*—although not always by these names. There remains in all series a residue of "mixed," "large cell," "*polygonal*,

† Differential count normal in all cases

extensors of the left wrist became manifest This weakness had disappeared by the morning of the seventh day Reflexes were undisturbed On the evening of the seventh day his condition became generally worse with increased photophobia, occipital headache, and pronounced increase in limb pain Further examination of the C.S.F. again revealed no abnormality After this exacerbation, which lasted for thirty six hours, the patient's condition steadily improved, and fourteen days after the onset he had no symptoms beyond a varying degree of headache At this stage a diffuse erythematous rash on the trunk developed and persisted for forty-eight hours On discharge a week later he was well, apart from continuing headache, which was indeed still present three months later There was no muscle tenderness or weakness, nor any change in the tendon reflexes During the latter part of his illness he had become depressed and morbidly introspective about his symptoms

Laboratory Investigations

In all cases the C.S.F. was examined, total and differential white blood cell counts were done, and the urine was tested

The C.S.F. was normal except in 1 case, where the fluid contained 6 lymphocytes per c mm and 86 mg of protein per 100 ml, with a moderate increase in globulin, the Lange curve was normal, as were the values for glucose and chloride

In all cases a slight leucocytosis was found, with normal differential pattern (see table)

No abnormality was found in the urine

Agglutination tests against influenza A and B, brucellosis, and leptospirosis were performed on serial specimens from all patients, all were negative and no rising titres were observed No cold agglutinins were detected in the blood of any of the patients at any stage

Fæces from the 4 most severe cases, including the 1 patient with an abnormal C.S.F. were inoculated into mice and tissue cultures were set up for Coxsackie and poliomyelitis viruses at the Institute for Research into Poliomyelitis, Hamburg, in no case was any virus isolated

Discussion

Epidemiology

All the patients had been in Berlin for at least four weeks before the outbreak, and none of those who before this time had come from England had come from an area where poliomyelitis was epidemic or endemic Four weeks before the outbreak there had occurred in the army population of the city a single case of poliomyelitis, but there was no possible direct contact between this case and those described here In the preceding month there had been 21 cases of poliomyelitis notified in the civilian population of the Western sectors, but none of these had occurred in the British sector, where the troops were stationed Figures for the Russian sector were unobtainable

As I have said, all the 6 "primary" cases came from the same barrack block, and the 7th case was in an orderly who had been nursing the initial 6 The men slept in small barrack rooms, and, while no two cases came from the same room, case 1, in his capacity of night orderly sergeant, had had close range conversations with all the other patients within a few days before admission His "date of onset" preceded all others by at least a day While the explosiveness of the outbreak gave the initial impression that this might be a food- or water-borne infection, it is improbable that this was so That it was more likely to have been airborne was suggested by two facts Firstly, the entire battalion was fed from a communal kitchen and shared communal canteen facilities, yet the cases occurred among the occupants of one block only Secondly, 1 case occurred in a nursing orderly, when hand-washing and disposal of excreta were being stringently observed

The time relation of the initial outbreak to the infection of an orderly within four days of coming into contact with the affected men suggests a short incubation period —certainly not more than four days

While there were clinical differences between this syndrome and poliomyelitis, it was the epidemiological pattern which first indicated that this was not poliomyelitis In outbreaks of poliomyelitis more than one case in a single household is not uncommon, but an outbreak of poliomyelitis proper can rarely, as in the present series, start explosively, affect only a few close contacts, and end as rapidly as it has begun

Diagnosis

When the 1st case was seen, with headache, limb pains, photophobia, neck stiffness, and an abnormal C.S.F., non-paralytic poliomyelitis was diagnosed with a fair degree of confidence, and the illness was notified as such, and the 2nd case a day later, with normal C.S.F., was again regarded as poliomyelitis When, however, all the cases appeared, none with persistent paralysis and only 1 with abnormal C.S.F., it was clear that this diagnosis could no longer be entertained

In poliomyelitis the C.S.F. may be normal apart from an increase in the protein content with no corresponding pleocytosis, or even completely normal, but such a state is usually found in no more than 5% of cases McAlpine et al (1947) and Toomey (1941) go so far as to say that in such cases poliomyelitis should not be diagnosed, but certainly, more than one abnormal C.S.F. would be expected in an outbreak McAlpine et al., in a review of 104 cases, found, too, that less than a quarter were non paralytic It was therefore, by viewing the outbreak as a whole in its epidemiology and clinical features that it was differentiated from poliomyelitis This is the experience also of others (Sigurdsson et al 1950, Acheson 1954, Macrae and Galpine 1954)

Virus meningitis and the various forms of encephalitis were excluded by the normal C.S.F. The clinical picture resembled that of true influenza, to exclude this with certainty is difficult, but the limited outbreak, the absence of the disease in the neighbourhood, and the negative agglutination reactions were thought to put it out of court Bornholm disease was considered, but in this series the clinical picture differed from that usually described, in no case was there any abdominal or chest pain, the pyrexia in all cases was mild, and the limb pains were not spasmodic In their study of

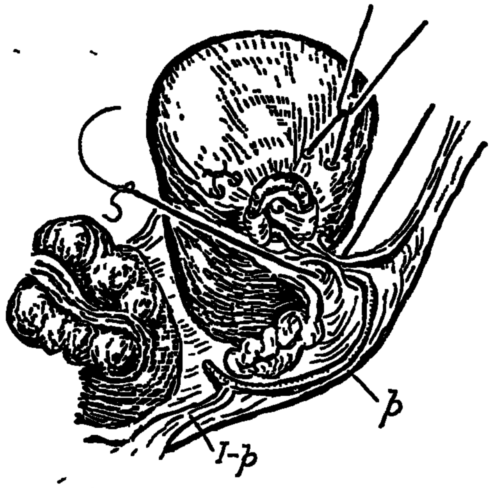

Fig 3—Polyethylene cord passed into uterus through peritoneal lined opening p, polyethylene cord, I p infundibulo pelvic ligament

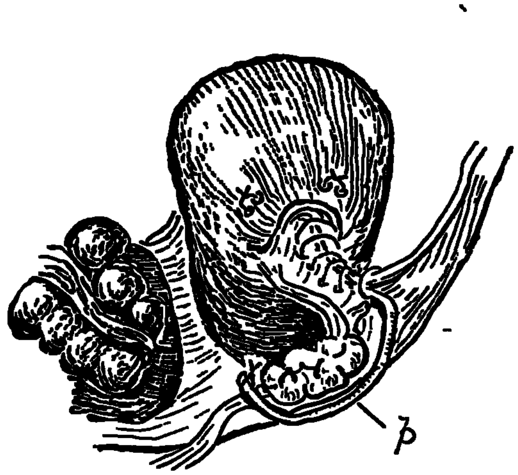

Fig 4—Polyethylene cord enclosed in peritoneal channel by continuous suture over round ligament p, polyethylene cord

the uterine wall (fig 2) The cornu of the other side is reamed and peritonised in the same way Polyethylene cord 2 mm in diameter is passed into the uterine cavity through the artificial aperture (fig 3) The free ends of the polyethylene cord are sutured to the infundibulo pelvic ligament near the ovaries A peritoneal channel is made around the polyethylene cord on each side, where it emerges from the uterine aperture, for 3–4 cm by a suture of continuous 00 chromic catgut, in this way the round ligament is oversewn by a fold of broad ligament to enclose the polyethylene cord (fig 4)

Where an ovary has previously been removed the operation is done on one side only, and the uterine end of the polyethylene cord is brought through the cervix The polyethylene cord is left in situ for 90 days The patient is given vitamin C 200 mg t d s for 6 weeks before the operation and antibiotics cover for 90 days afterwards

Discussion

Surgical methods for treating occlusion of the uterine tube have been reviewed and discussed by Siegler and Hellman (1956) and Greenhill (1956) The methods used have been mainly either partial reconstructive plastic techniques (Szendi 1953, Jarvinin 1954) or tubo uterine implantation (Green Armytage 1952) More recently transplantation methods have been tried, with either amniotic membrane (Ten Berge and Tik Lok 1954) or, experimentally in dogs, segments of vein or artery (Davids and Bellwin 1954) Foreign material—e g, polyethylene tubing and membrane—have also been used (Mulligan et al 1953)

There are some objections to the use of transplantation methods mainly because of tissue reactions, to some extent the same objection might be raised in the case of foreign substances such as polyethylene There exist also the uncertain effects of such synthetic materials in the special circumstances of fertilisation and cleavage in the uterine tube

The present operation, which has been devised to circumvent these difficulties is based on the fact that the ovarian germinal epithelium and the peritoneum both have their origin in the cœlomic epithelium of the young embryo (the uterine tube also is closely related developmentally to the cœlomic epithelium since it arises by infolding of this membrane) Therefore there is a rational basis for reconstructing a uterine tube from peritoneal epithelium

Oversewing the round ligament into the wall of the reconstructed tube is designed to assist the transport of the ovum which is mainly effected by the activity of the uterus Together with the uterine tube, the uterus and round ligaments undergo contractions at ovulation, and it is presumed that, at this time and at subsequent fertilisation muscular contractions of these structures continue whether or not a uterine tube is present The lack of cilia in the reconstructed tube is of lesser importance since the uterine tube is normally incompletely ciliated, transportation of the ovum is almost certainly effected normally by muscular activity of the tube and uterus

Where less extensive reconstruction is required, the same principle could be applied by a simple modification of technique So far partial reconstruction according to this principle has not been described

Summary

A total plastic reconstruction of the uterine tube from local peritoneal tissue is described, and the theoretical basis for the operation is outlined

The *operation consists of oversewing the round* ligament with broad ligament peritoneum over a former of polyethylene cord, a new interstitial section and uterine ostium are reamed and lined by metrial peritoneum

Four operations have been done using this technique

Where complete replacement of the tube is not required a simple modification using the same principle may be tried

CARCINOMA OF THE BRONCHUS
HISTOLOGICAL CLASSIFICATION

C Raeburn
M R C S
MORBID ANATOMIST

W W Walther
M B Lond
AREA PATHOLOGIST

AREA LABORATORY, WHIPPS CROSS HOSPITAL, LONDON

Numerous histological classifications of bronchial carcinoma have been suggested These have often been based upon absurdly few cases, but Barnard (1938) and Bryson and Spencer (1951) classified a large amount of necropsy material

At this laboratory we have for the past four years classified lung cancer in the manner described by Walter and Pryce (1955) and find this to be satisfactory from the point of view of the histologist, but during an investigation into the possible relationships between blood groups and cancer it became obvious that a more precise technique of classification was needed

Most workers recognise three types of lung cancer—the oat cell the squamous cell, and the adenocarcinoma—although not always by these names There remains in all series a residue of " mixed," " large cell," " polygonal

TABLE I—CLINICAL FINDINGS IN 39 PATIENTS SIX YEARS AFTER HAVING AKUREYRI DISEASE

—	No	Completely recovered		Nervous and neurological complaints	Muscle tenderness	Neurological signs
		Subjectively	Objectively			
Severe cases in 1949	23	2	5	19	12	15
Slight cases in 1949	16	3	7	13	8	3
Total	39	5	12	32	20	18

Disturbances of cutaneous sensibility were slight, but in all the cases their distribution either followed the nerves or corresponded to spinal segments

Discussion

There is increasing evidence that a previously unrecognised infection has presented in various parts of the world during the past seven years A complete description of the clinical features of the infection will not be attempted here, but the workers cited above are in relatively good agreement about the clinical picture

The main features of the disease may be said to be as follows

The incubation period is probably about a week, the onset of symptoms may be sudden in some cases but more often it is insidious, the initial symptoms are usually low pyrexia with headache, especially in the back of the head and nape, and pains in the back and shoulders are very common and often radiate into one or more limbs

The painful muscles are usually tender to the touch—sometimes extremely so The patient complains of tiredness particularly after even slight exertion These symptoms usually either improve or disappear within a few days to a few weeks but may persist for months or even for years Many patients complain of sleeplessness, nervousness, and loss of memory

In some cases paresis develops from two days to four weeks after the onset of the disease In some patients there is a relapse, paresis attacking a new limb after paresis earlier elsewhere in the body A relapse of paresis has been observed as late as eight weeks after the first paresis

Paresis is usually limited to either one muscle or a group of muscles but may affect either a whole limb or more than one limb The tendon reflexes are usually present, although decreased, except in the most severe cases Even if true paresis seems only slight, the affected limbs tire very easily

Paresis tends to improve, but improvement may be very slow

Disturbances of skin sensibility are common Many patients complain of numbness or of paræsthesiæ in the affected limbs Hypoæsthesia or hypoalgesia are sometimes observed in the affected limbs

TABLE II—RESIDUAL SIGNS AND SYMPTOMS FOUND SIX YEARS AFTER ATTACK OF AKUREYRI DISEASE

Signs and symptoms	No of cases which were severe in 1949 and now show symptoms	No of cases which were slight in 1949 and now show symptoms
Nervousness and general tiredness	18	10
One group of muscles or one limb tires easily	7	
Muscle pains	16	8
Paræsthesiæ	4	
Sleeplessness	4	2
Loss of memory	5	3
Paresis	8	1
Atrophy of muscles	4	2
Reflex anomalies	4	1
Tenderness of muscles	10	
Tenderness of nerves	2	
Hypoalgesia hypoæsthesia or dysæsthesia	8	
Slight decrease of sensation to vibrations	3	
Slight ataxia of one limb (?)	2	
Slight decrease of deep sensibility (?)		1

True stiffness of the neck is seldom observed, but the patients often feel pain in the neck and down the back when the head is bent forward Lasegue's sign is occasionally positive

Nervousness, loss of memory, sleeplessness, and general tiredness are very often complained of and may persist for a long time

The number of cells in the cerebrospinal fluid is apparently within the normal range in most cases

No deaths have been reported, there has therefore been no opportunity of studying the distribution and nature of possible anatomical lesions

The findings reported here indicate that, in some cases, many of the signs and symptoms may persist at least for several years

We suggest that this condition be called (as in Iceland) Akureyri disease rather than (as some call it) Iceland disease until a more appropriate name can be suggested when we know more about its cause and the anatomical basis for the signs and symptoms which characterise it

Summary

The clinical findings in 39 patients six years after an attack of Akureyri disease are described

Many of the patients still complained of nervousness, tender muscles, pains, and tiredness

Signs of paresis, hypoalgesia, and hypoæsthesia were not uncommon, and other complaints are listed

A short description of the clinical features of Akureyri disease is given on the assumption that at least several of the outbreaks resembling it and described during the past six years form with it a nosological entity

STAPHYLOCOCCAL PNEUMONIA IN INFANTS

M E DISNEY
M D Lond, M R C P
CONSULTANT PÆDIATRICIAN

JILL WOLFF
M B Birm
JUNIOR HOSPITAL MEDICAL OFFICER

B S B WOOD
B A, D M Oxfd, M R C P, D C H
CONSULTANT PÆDIATRICIAN

DUDLEY ROAD HOSPITAL, BIRMINGHAM

EACH winter many infants aged less than 2 years are admitted to Dudley Road Hospital with acute infections of the lower respiratory tract Since cultures made from the upper respiratory tract are so uninformative, we decided to culture lung juice obtained by thoracic puncture (Eyre 1910, Abdel Khalik et al 1938, Alexander et al 1941) in selected cases

Like Alexander et al (1941) we found no ill effects from this procedure, and we tentatively extended it but never used it as a routine Our early results suggested that, in infants with either bronchiolitis or bronchopneumonia without clinical evidence of consolidation, thoracic puncture yielded lung juice that was usually sterile In infants with definite local signs of consolidation thoracic puncture often yielded lung juice from which bacteria were grown, most commonly a coagulase positive *Staphylococcus aureus*—which is what is meant in this paper by *Staph aureus* In 1953 and 1954 thoracic puncture was therefore confined mainly to infants with localised signs of pneumonia will stand up to much wear if they are squeezed and not wrung out The work of the nurses is also decreased because the washing of many packs is avoided

Disadvantages of these sponges are that they are somewhat bulky, blunt dissection is not so easy as with gauze, and they may get covered with a layer of fibrin during operations unless frequently washed Nevertheless I believe that the virtues of these sponges make them worthy of a more extended trial in surgery

I am indebted to the manufacturers, Messrs Sponcel Ltd, 40, Chancery Lane, London, W C 2, for their help with this trial They are willing to supply any size required

PREVENTION OF STREPTOMYCIN DERMATITIS IN NURSES

GWYN HOWELLS
M D Lond, M R C P
ASSISTANT CHEST PHYSICIAN, DERBY

CONTACT dermatitis in persons handling streptomycin was reported by the Council on Pharmacy and Chemistry (1947), and by Rauchweiger et al (1948) who described 6 cases in nurses Crofton and Foreman (1948) reported 4 cases of dermatitis in about 80 nurses handling streptomycin in the early trials made by the Medical Research Council

The Ministry of Health (1953c) estimated the prevalence of sensitisation in handling antibiotics to be as high as 3 5% By far the largest number of the nurses were sensitive to streptomycin, and most of the remainder to penicillin, 188 cases of streptomycin sensitivity were reported from 146 centres

Anyone concerned in the manufacture, preparation, or other handling of streptomycin may develop sensitivity, but by far the highest incidence is in nurses The greatest risk seems to be to those preparing and injecting the solution

The main use of streptomycin being in the treatment of pulmonary tuberculosis, the largest number of injections is given in chest hospitals and sanatoria Since the modern tendency is to give streptomycin for increasingly long periods, any sanatorium or district nurse may be called on to give a very large number of injections

So far as nurses are concerned, the problem falls into two parts the avoidance of sensitisation and the protection of the sensitised

The Ministry of Health (1953a) lists thirteen possible precautions or variants of precautions in giving the drug At the same time the Ministry of Health (1953b) issued advice by an expert committee on the prevention of skin reactions These precautions can be summed up by saying that a strict and rigorous drill is essential to those administering antibiotics, from the preparation of the dose through the injection to the final disposal of the utensils It was, however, reported that despite adherence to the most careful technique and the wearing of gown cap, and mask nurses had still become sensitised The *British Medical Journal* (1953) described these precautions as inadequate and suggested additional measures including the exclusion of anyone with a history of allergy or dermatitis the preparation of injection solutions in a central department, and the delegation of the task of preparing and administering streptomycin to one or two nurses in each ward The last named recommendation, though it would reduce the general risk would increase that of nurses selected for the duty

The sensitised are at an unfortunate disadvantage professionally and possibly clinically The nurse, particularly in a sanatorium, who cannot give streptomycin is handicapped in her profession and provides an administrative problem in hospitals already short of staff In addition her health may be endangered if she later needs streptomycin for herself as a patient A further danger is that sensitisation to one antibiotic is often associated with sensitisation to another Some of those whose reactions have been mild have been able to return to giving injections, but many have been permanently unable to do so Crofton (1953) succeeded in desensitising 2 nurses but says that to do this may take several months and produce minor reactions According to the Ministry of Health (1953c) other workers have had less success Apart from removing the patient from the contaminating substance no other treatment is curative

Method

I have found that sensitisation can be avoided if streptomycin is injected from cartridges by what may be described as a "no touch" technique because there is little risk of the handlers coming into contact with the streptomycin, which is contained in a glass cylinder sealed at each end with rubber The rubber at one end acts as the plunger, and the other end is pierced by the dummy needle on the inside of a 'Mitrex' syringe, an all metal syringe similar in principle to a dental syringe and separable into its component parts and easily sterilisable The only parts of the apparatus that come into contact with the streptomycin solution are the dummy needle and the needle through which the injection is given The nurse who prepares and measures the dose is exposed only to the risk of disposing of the needle and one small part of the metal syringe

Case-reports

Case 1—A male nurse, aged 40, had a previous history of unspecified dermatitis in childhood but no skin complaints or allergy since He had first given streptomycin in 1946 and had had symptoms of sensitivity three days after his first contact, by which time he had given only five or six injections He developed severe circumorbital œdema and an irritating erythematous rash which affected his hands severely and his forearms slightly His fingers became œdematous, and the rash progressed to vesiculation and desquamation He was ill for about three weeks Over the next few years he made repeated efforts to give streptomycin but always had a return of symptoms despite the most stringent care His condition became such that he "dared not go into a room while an injection was being prepared or given" He was not sensitive to other antibiotics

Since August, 1955, using cartridges, he has been able to give twenty injections of streptomycin daily without *incurring* any reactions During this time he once attempted to give streptomycin by the usual method but underwent his usual reaction to it

Case 2—A female nurse, aged 35, first started giving streptomycin in mid 1948 She had no previous history of either skin disease or allergic complaint In various hospitals and centres she gave large amounts of streptomycin but had no reactions until July, 1953 She said she had become over confident in handling streptomycin and, in particular, was careless in expelling the excess of any dose into the air and in handling syringes when putting them into the steriliser after use Her reaction was striking, with severe circumorbital œdema and catarrhal conjunctivitis, a generalised erythematous rash (on the first occasion it was suspected of being measles), malaise and pyrexia up to 103·1° lasting a week The rash on her forearms and hands vesiculated finally became eczematous, and remained for three months although the rash elsewhere on her body cleared within two weeks She was off duty for four months

In the latter part of her convalescence she was given an intradermal test involving the injection of a small amount of streptomycin ' This produced not only a large weal and flare but also a mild recrudescence of the rash

After recovery an attempt was begun by a dermatologist to desensitise her, but she refused to continue with this because the first and second injections produced itching of the skin and she was afraid of a relapse She made two subsequent attempts to give streptomycin but on each occasion after five or six injections, had a reaction

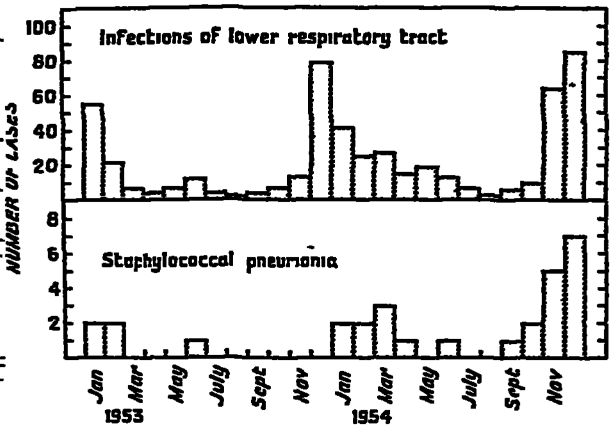

Fig 2—Seasonal distribution of infections of lower respiratory tract and of staphylococcal pneumonia.

even this so-called primary staphylococcal pneumonia is probably secondary to an antecedent virus infection (Chickering and Park 1919, Scadding 1937, Wallman et al 1955)

Radiography

The radiographic appearances varied considerably and, as Campbell et al (1954) found, changed very rapidly A small opacity would become generalised pleuritis or an empyema, or blebs would appear with alarming speed. Of 26 infants radiographed, 4 had an opaque lung field and presented little difficulty in diagnosis after examination of the pleural fluid Of the remaining 22 infants radiographed only 9 had signs which differentiated them from other cases of pneumonia these findings being those of pneumatocele or bleb formation, which were considered by Blumenthal and Neuhof (1946) to be typical of suppurative pneumonia but are often confused with congenital cysts of the lungs (Conway 1951) In 6 other cases there was localised pleuritis at an early stage, shown by a thickened pleural edge or by a diffuse "ground glass" opacity over one zone but these were not sufficiently clear cut to be diagnostically helpful

Bacteriology

Swabs

Laryngeal, postnasal, or throat swabs taken from 19 infants revealed *Staph aureus* in 5 of them, this is lower than the expected staphylococcal carriage-rate in the upper respiratory tract, probably because dry swabs were used Blood was not cultured except in 1 infant (in whom it proved sterile)

Thoracic Puncture

This consisted in inserting a dry sterile 16 gauge or 18 gauge needle attached to a 5-ml syringe into the affected area after preparing the skin with either iodine or spirit If no exudate was obtained from the pleural cavity, the needle was advanced a further centimetre or two, suction on the syringe being maintained during both insertion and withdrawal If visible exudate was seen in the syringe it was inoculated directly on to either blood-agar or chocolate agar plates If no exudate was seen, the needle was inserted into a bottle containing 5 ml of glucose broth, which was sucked up into the barrel of the syringe and discharged back into the bottle After incubation over night the broth was subcultured on to the solid media

25 infants were subjected to thoracic puncture Although 8 presented clinical evidence of pleural effusion, only 4 had frank empyemata on admission In the remaining 4 a small drop of pus appeared in the syringe and was cultured direct All 8 specimens yielded *Staph aureus* in pure culture In 17 cases no visible exudate was seen in the syringe, and on these the value of lung puncture as a diagnostic aid can be assessed In 14 of them *Staph aureus* was cultured at the first attempt so culture of lung juice in these infants enabled staphylococcal pneumonia to be diagnosed early and contributed to their recovery from the acute stage, in none of them did an empyema develop On the other hand, in 3 infants the initial lung puncture was sterile and misled us

The question of false positives must also be considered In more than 100 lung punctures done before during, and after the present series *Staph aureus* was isolated in 3: 2 of these children were aged more than 2 years, and 1 infant with a positive lung puncture had no other evidence of pneumonia It is presumed that this was due to the accidental introduction of *Staph aureus* from skin or air into the broth, as occasionally happens in blood-culture

Sensitivities

Each strain of *Staph aureus* isolated from the cases admitted in 1954 was tested against six antibiotics (penicillin, streptomycin, chloramphenicol, chlortetracycline, oxytetracycline, and erythromycin) by the following method

A single colony of *Staph aureus* was spread evenly over an agar plate in three directions to ensure a smooth confluent growth Six 'Sentest' tablets (Evans Medical Supplies Ltd) were placed at equal intervals round the plate Each tablet contained a given amount of the various antibiotics penicillin 0 5 I U, streptomycin 20 µg chloramphenicol 40 µg, chlortetracycline 10 µg oxytetracycline 10 µg, and erythromycin 1 µg After incubation over night the results were read according to the zones of inhibition of growth around the tablets varying from very sensitive to resistant

For our present purpose the strains are classified only as either sensitive or resistant, the method not being sufficiently accurate for more detailed division (table III) The correlation between chlortetracycline and oxytetracycline was absolute, except for 1 case where complete resistance was shown to chlortetracycline and slight sensitivity to tetracycline

TABLE III—ANTIBIOTIC SENSITIVITY OF STRAINS ISOLATED FROM TWENTY INFANTS

No of infants	Penicillin	Streptomycin	Chloramphenicol	Chlortetracycline	Oxytetracycline	Erythromycin
4	S	S	S	S	S	S
11	R	S	S	S	S	S
1	S	P	S	S	S	S
1	S	S	S	P	S	S
2	P	R	S	S	S	S
1	R	P	P	R	P	S

R resistant　S sensitive

All the strains were sensitive to erythromycin, all but 1 sensitive to chloramphenicol, and all but 2 to both chlortetracycline and oxytetracycline

Treatment

This followed the current lines of alleviating anoxæmia with oxygen and bringing the infection under control with an appropriate antibiotic as soon as possible At the beginning of the study penicillin was usually given at the start of treatment, later on we learned to suspect staphylococcal infection on clinical grounds and tended to use erythromycin pending the results of bacteriological examination Erythromycin was used in 17 cases altogether, but our results do not show it to be, either alone or in combination, superior to other antibiotics It is now our practice to keep erythromycin in reserve for cases showing bacterial resistance to all the other antibiotics Where an empyema had developed, either penicillin or streptomycin was injected locally In 1 case a pneumothorax developed, necessitating intercostal drainage with water-seal

Result

The humidifier was first tested by mouth-breathing with a healthy person. With a room temperature of 18°C the temperature of the inspired air was 26–27°C. The water content was equivalent to a humidity of 70–80% saturation at body-temperature. Since this is equivalent to 130% saturation at 26°C it is likely that some of the water was in droplet form.

The apparatus was then used in ventilating a very heavy man (about 120 kg.) who needed a tidal air of about 600 c.cm. With a room-temperature of 14°C the temperature of the inspired air was 24–25°C. The temperature of the expired air after passing out through the humidifier fell to 15°C. The water content of the inspired air was equivalent to a humidity of 70–80% saturation at body-temperature. The amount of water collecting in the expiratory tube after passing through the humidifier was very small. On one occasion it was collected for three hours and found to be 10 ml.

The respiratory gas pressure at the endotracheal junction was recorded in this case with the humidifier in place complete and then with the gauze removed. There was no appreciable difference in the two curves. The relatively high pressure needed for the ventilation was normal for this patient and a consequence of his massive chest.

This patient was successfully ventilated for nine weeks with the humidifier. Throughout this period his bronchial secretions were thin and easily aspirated. The humidifier was also used for 5 other patients, in 1 for nine weeks. In all cases the bronchial secretions remained thin.

Discussion

The water content of inspired air produced by this apparatus, equivalent to 70–80% saturation at body temperature, was considerable though short of the physiological figure. While this apparatus was being used, the bronchial secretions remained thin and were easily aspirated. The Danish originators of this technique of positive pressure ventilation seem to have used methods of humidification which probably produced a much lower humidity without harmful results in their very large series of cases. Probably a lower content than physiological is satisfactory. If this is so, the small size and simplicity of this apparatus are great advantages. Anchored firmly in the infraclavicular fossa it takes the weight of the inflating tubes and prevents them from pulling on the endotracheal tube. The small volume of air this apparatus encloses adds little to the work of the inflating pump. It is true that the volume must be included in the patient's respiratory dead air space, but it is considerably less than the decrease in dead space due to a tracheotomy (Radford et al. 1954). The resistance of the gauze to the air flow is surprisingly little.

Summary

A simple humidifier for positive pressure ventilation through a tracheotomy is described.

It has been used with satisfactory results in 5 cases.

It produces a water content equivalent to 70–80% saturation at body temperature.

Its advantages and disadvantages are discussed.

I wish to thank Dr. Ruth Grose for her assistance, and Dr. J. Macrae for his help and encouragement with this paper. This apparatus can be obtained from Willcocks (Clevedon) Ltd., Clevedon, Somerset.

ACUTE MYELOID LEUKÆMIA AFTER RADIOACTIVE-IODINE THERAPY

JOHN D. ABBATT

M.B. Edin., D.M.R.T.

MEMBER OF EXTERNAL SCIENTIFIC STAFF, MEDICAL RESEARCH COUNCIL, POSTGRADUATE MEDICAL SCHOOL OF LONDON

HELEN E. A. FARRAN

B.Sc. Melb.

PHYSICIST, NEW END HOSPITAL, LONDON

RAYMOND GREENE

M.A., D.M. Oxfd, F.R.C.P.

PHYSICIAN, NEW END HOSPITAL, LONDON

IN view of the association between ionising radiations and leukæmia we report here the case of a patient who was treated with radioactive iodine for thyrotoxicosis and later died of acute leukæmia.

Case-report

A married woman, aged 67, was first seen by Dr. H. F. S. Pearson at the Whittington Hospital in May, 1953. She had congestive heart failure apparently induced by bronchitis, but it seemed to Dr. Pearson that she was also thyrotoxic, and after her recovery she was referred to the department of endocrinology at New End Hospital. Here she complained of a recent increase in irritability and anxiety. For the previous two years she had been intolerant of heat and had perspired more freely than usual. Her weight had decreased from 11 st. 4 lb. in 1945 to 8 st. 4 lb. in 1951 and 7 st. 4 lb. in 1952 and was then 6 st. 9 lb.

On examination she was thin and tremulous, with pulse-rate 120, blood-pressure 230/130 mm. Hg, and frequent extrasystoles. No signs of congestion were present. A bilateral nodular and partially retrosternal goitre was present. In view of the patient's condition and the possible technical difficulty of thyroidectomy, treatment with radioactive iodine was proposed.

Treatment.—Carbimazole 10 mg. t.d.s. with thyroid gr. 1 was given daily from July 8 to Aug. 11, 1953, when the dose of thyroid was reduced to gr. $^1/_2$ daily. The patient was admitted to New End Hospital in September, 1953, when thyrotoxicosis was still present and signs of cardiac failure had reappeared. After all treatment had been stopped on Sept. 16, 1953, radio-iodine tests (table I) and a blood-count (table II) were made. A therapeutic dose of 17 mc of ^{131}I was given orally on Sept. 23, 1953. Effective half-lives of 7·0 and 7·6 days in the body and neck were observed as a result of this dose. The energy absorption * in the neck during the first fortnight after treatment was 22,000 rad. More than 90% of the total integral dose was received during the first twenty-four hours, 0·16 megagramrad being absorbed during the first day and about 0·001 megagramrad daily thereafter.

Course.—After the radio-iodine treatment in September, 1953, the patient improved and became euthyroid. Although the congestive cardiac failure did not disappear it greatly improved, and the patient's main complaints were of a troublesome cough and slight dyspnœa on exertion in the winters of 1953–54 and 1954–55. In January, 1954, her condition was considered clinically to be euthyroid, a finding which was confirmed by a radio-iodine excretion test (table I). On April 3, 1955, she was readmitted for assessment when she was considered to be relatively well and euthyroid, with a minor degree of congestive cardiac failure. When due for discharge, however, on April 6, 1955, she had painless hæmaturia for three days. The only clinical abnormality noted was several enlarged cervical glands. Severe progressive anæmia developed, but no other gross hæmatological abnormality was rticularly noticeable in 2 infants who died within a w hours of admission, a little fibrino-purulent exudate as present between the otherwise adherent thickened yers of pleura

---

* The energy absorbed by the blood is calculated by assuming that the β radiation due to an activity in the blood itself of 1 μc per ml. is 0·418 rad per hr. and that the γ radiation is contributed from the activity dispersed through the body as a whole. Bush's (1949) tables give, for a patient weighing 45 kg. and 156 cm. tall, a value of 0·255 rad per hr. per μc per kg. of body weight. The dose to the marrow is assumed to be of the same order as that to the blood. The presence of bone surrounding the marrow would only affect the γ contribution and would only be significant during the first twenty-four hours, when it might increase the total from 2·87 rad to 4·00 rad at the most. It would be an increase of less than 10% over the first fourteen days, or even of the total received, and the other errors are far greater than this.

Pus in the aspirating needle or syringe depends on its lance passage through a purulent area rather than herent pleura Washing out the syringe and needle ith broth therefore seems to afford the best chance of covering the organism, although it carries with it the creased risk of accidental bacterial contamination

Despite the warning given by Lelong and Alison (1953) at "La ponction exploratrice peut être dangereuse dans s cas" we had no direct sequelæ of thoracic puncture this series, but 1 infant had a pyopneumothorax ght days later The fact that this complication is very ommon in staphylococcal pneumonia seems to exonerate he lung puncture from blame We repeated thoracic uncture in several relapsed cases without producing ny untoward result Before, during, and since the eriod covered by this report more than a hundred lung unctures have been done in various infections of the ower respiratory tract on 4 occasions a partial pneumothorax developed but caused no detectable symptoms nd the air was reabsorbed in a few days

It therefore seems that the first definite sign of localised neumonia in infants aged less than 2 years demands mmediate treatment as a potential staphylococcal nfection We do not suggest the use of lung puncture as a routine diagnostic measure at this stage, but its use has made us more familiar with the early signs of staphylococcal pneumonia in infants, and this recognition has in some instances perhaps led to more effective initial treatment reflected by somewhat lower empyema and mortality rates than those usually reported

If present trends continue (Barber and Burston 1955), the list of antibiotics likely to be effective will grow shorter, and in this unhappy event lung puncture may have to be done routinely to determine the sensitivity of the "unconquered staphylococcus"

Summary

In 1953 and 1954 35 cases of staphylococcal pneumonia were diagnosed in 530 infants, aged less than 2 years, admitted with infections of the lower respiratory tract Of the 35 cases 29 were "primary"

In 14 out of 25 cases lung puncture contributed to early diagnosis of staphylococcal pneumonia

Results of treatment confirm the necessity for long-continued administration of antibiotics

We wish to thank Prof J M Smellie for advice and criticism in the preparation of this study, and our ward sisters and house physicians for their skill and cooperation

STAPHYLOCOCCAL INFECTION OF THE LOWER RESPIRATORY TRACT IN ADULTS WITH INFLUENZA

Arthur Duncan Evans
B Sc, M B Wales, Dip Bact
SENIOR BACTERIOLOGIST, PUBLIC HEALTH LABORATORY, CARDIFF

Myrddin Evans
B Sc, M B Wales, M R C P
LATE LECTURER IN MEDICINE, WELSH NATIONAL SCHOOL OF MEDICINE

Until 1932 influenza could be diagnosed only on clinical grounds, but nowadays the relationship of influenza virus to epidemic influenza and to the "influenzal" pneumonias can often be established by demonstration of either the virus or specific antibodies in the serum

Staphylococcal pneumonia is rare but seems to occur most commonly as a complication of influenza The number of patients with staphylococcal pneumonia and satisfactory evidence (demonstration of either virus or antibodies) of recent or current influenza is unfortunately small

3 rapidly fatal cases of staphylococcal pneumonia which also yielded influenza virus were reported by Scadding (1937) and Stuart-Harris et al (1938) Single cases were recorded by Stokes and Wolman (1940), Himmelweit (1943), and Burnet et al (1946), and 2 by Parker et al (1946)

Evidence of coincident or recent infection with influenza virus has been provided by hæmagglutination and complement-fixation tests in a greater number of patients 45 of 54 cases of staphylococcal pneumonia were studied in Sheffield and other areas in 1949–51, and cultural or serological evidence of influenza either coincident with or shortly before the lung involvement was obtained in 24 (Williams 1953)

Staphylococcal pneumonia in the absence of influenza is very rare, but there are several instances of staphylococcal pneumonia in which search for the influenza virus was unsuccessful (Andrewes et al 1935, Pearson et al 1941, Stuart Harris et al 1949)

There is no evidence that the influenza virus isolated from cases of staphylococcal pneumonia has unusual properties, but Stuart-Harris (1953) comments that a large quantity of the virus can be detected in the lungs Until recently there had been no extensive study of the staphylococci found in sputum or lungs of patients with pneumonia during influenza epidemics, but it is agreed and emphasised by all workers that the staphylococci are present in prodigious numbers Bacteriophage typing of strains of *Staphylococcus aureus* from cases of influenzal pneumonia was done by Williams et al (1953), who found that the proportion of group I strains from non-fulminating types of pneumonia did not differ significantly from that in the nose of healthy carriers (about 25%), whereas 56% of strains from fulminating cases were of this group Since the excess of group-I staphylococci was observed in strains from a variety of sources and in two different epidemics, Williams et al believed it to be significant Not all the strains associated with the fulminating disease were resistant to penicillin

Clinical and Bacteriological Studies

During 1953 clinical and laboratory investigations were made on all adult patients with acute infection of the lower respiratory tract in the wards of the medical unit in the Cardiff Royal Infirmary Routine studies of 70 patients included frequent bacteriological examination of sputum and complement-fixation tests for evidence of infection with the viruses of influenza A and B, psittacosis, lymphogranuloma inguinale (L G I)

Secretions, which up to now had only been slight, gathered in large amounts in the nasopharynx, and cyanosis appeared for the first time. Tracheal and mandibular tug with twitching of the facial muscles was prominent. The patient's general condition degenerated rapidly. Since we had no previous experience with intermittent positive pressure respiration (I.P.P.R.) in infants we were reluctant to perform a tracheotomy, and so we tried a cuirass respirator. This was a failure and the patient's condition became desperate.

Tracheotomy and Artificial Respiration

A tracheotomy was done under local anæsthesia, and a flexometallic tube no. 1 inserted and stitched in. The V-shaped metal end was of the wide-bore type.

Ventilation was performed by means of "finger respiration." A continuous flow of oxygen was led into one limb of the V-tube; closing the end of the other limb produced inflation of the chest, while passive expiration occurred when the finger was removed. Various rates of flow were tried and it was found that a flow of 4 litres per minute was the most satisfactory.

Attempts were made during the next hour or so to provide mechanical respiration by means of the Radcliffe respiration pump, using air which was forced down one limb of the V piece. A water manometer, which could be set to allow the escape of air if the pressure rose above a set figure, replaced the Borden pressure gauge. Tubes of various lengths and diameters were placed over the free limb of the V piece, as in some anæsthetic techniques. The minute volume delivered down the other limb was increased; but ventilation remained inadequate, the heart rate slowed, and cyanosis followed, and finally this method was abandoned.

The original arrangement was restored with a Stott valve (Smith et al. 1954). A gasmeter-type spirometer at the outlet of the Stott valve showed the degree of ventilation, which was kept at 2.6 litres per minute as recommended by Spalding (1955). The water manometer was set to blow off at 8 cm. of water; the actual pressure used was about 6 cm.

Difficulties now arose with regard to the CO_2 tension. It was felt that it would be almost impossible to obtain arterial samples for gas analysis from such a small subject, and the CO_2 content of the expired air was measured as described by Harries and Lawes (1955), but little information of value was obtained by this method. The stroke rate of the machine was increased to its maximum of 45 per minute by altering the cogs. The depression of the water-level in the manometer suggested that possibly the inspiratory pressure was being maintained for too long a period, but this we were unable to alter.

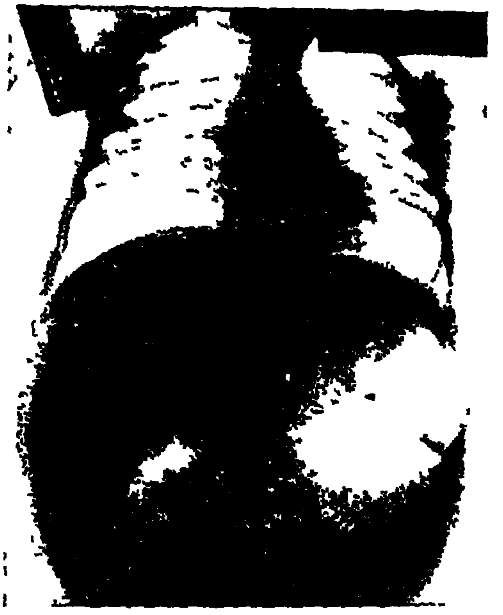
Hypercapnia

During the next two hours there was intermittent twitching of the facial muscles, the nose, the fingers, and the frontalis muscle with pronounced tracheal and mandibular tug. Repeated measurements of volume of the expired air showed that a minute volume of 2.6 litres was being maintained. Increasing the oxygen concentration did not appear to affect the twitching. The CO_2 content of the expired air at the outlet port of the Stott valve had risen from 1 to 2%. Muscular twitching has been reported to be a common sign of hypercapnia (Leake and Waters 1929, Waters 1937), and a return to finger respiration was made for short intervals to remove the assumed excess of CO_2. On each occasion this caused the twitching and tug to disappear within a short period.

After five hours on the machine the patient's condition became much worse. Twitching with tracheal and mandibular tug became pronounced, and the pulse was hardly perceptible. Aminophylline was administered, without effect. Mechanical ventilation was abandoned and a return made to finger ventilation with immediate improvement. An electrically controlled humidifier (Russell and Schuster 1953) was incorporated into the system but caused some difficulty because of condensation of water vapour, and eventually the humidifier was switched off.

Progress

Volunteers, including housemen and hospital assistants, were organised into six-hourly shifts, each shift consisting of two people who worked alternately for fifteen-minute periods. As the personnel were untrained in finger respiration the machine was used as a metronome; it was so altered that if the operator followed the machine by eye or by ear the inspiratory period was just under 0.5 sec. and the expiratory period approximately 0.7 sec. with the respiratory rate about 45 per minute.



Radiograph showing dilatation of stomach without surgical emphysema of mediastinum.

This system worked well for thirty hours. The infant was turned regularly at intervals, though air entry was good in all areas and there were no adventitious sounds except when the tube was allowed to slip too far in. Suction of the pharynx was only occasionally needed and suction down the tube was rarely necessary.

Twenty-four hours after the tracheotomy the infant opened her eyes and appeared to be conscious. Attempts at spontaneous respirations were made by the patient, but these became feeble if allowed to continue unaided for more than forty-five seconds.

Gastric Dilatation

Thirty-six hours after I.P.P.R. had been instituted the clinical picture changed rapidly for the worse. The abdomen became distended, and so ventilation was impeded. Some partially digested milk was vomited. Insertion of a rectal tube produced a large amount of fæces, and shortly afterwards the distension subsided and ventilation was more easily performed. An hour and a half later the distension returned to such a degree that it was only with the greatest difficulty that any ventilation could be achieved.

There was no air entry at either base and very little elsewhere; suction through the stomach tube produced nothing. By gentle pressure on the distended abdomen, however, large amounts of air and some fluid were squeezed out of the stomach and the distension became considerably less. Ventilation was now satisfactory. Radiographic examination at this stage showed "distended stomach; no sign of surgical emphysema in the mediastinum or free air in the peritoneal cavity" (see figure).

In the next six hours there were three further attacks of acute dilatation of the stomach, each of which prevented any visible movement of the chest wall or abdomen and led to cyanosis and cardiovascular changes. Each attack was relieved with difficulty by gently squeezing the abdomen, suction through the stomach tube having little effect. During these attacks care was taken that the inspiratory pressure did not become excessive, and such ventilation as could be achieved was by intermittent insufflation, the excess air escaping from the partly closed end of the free limb of the V piece during inspiration.

Deterioration and Death

On the third day after admission the abdomen was distended to a far greater extent than previously; the chest wall appeared to be fixed in the maximum inspiratory position and no air entry could be heard in any area of the lungs. Each attempt at inflation appeared to make the distension worse. A similar state of affairs, where the chest was fixed in the maximum inspiratory position but without abdominal distension, had been seen by us in an adult where the cuff had herniated round the end of the endotracheal tube, forming

TABLE II—STAPHYLOCOCCAL α-ANTITOXIN LEVELS (I U PER ML) OF 4 PATIENTS WITH COMBINED STAPHYLOCOCCAL AND INFLUENZAL INFECTIONS

Case no	On admission	After 1 week	After 3 weeks	After 8 weeks
1	Not detectable	Died		
2	Not detectable	0 3	0 8	Not assessed
3	Not detectable	Died		
4	Not detectable	0 2	0 8	1 6

Materials and Technique

Serial dilutions of inactivated patient's serum made up to a unit volume of 0 4 ml with saline solution were mixed with 0 4 ml of toxin diluted with a mixture of 3 parts of saline solution and 1 part of broth to contain Lh/10 or in some cases Lh/50 The serum-toxin mixture was incubated for 30 minutes in a water-bath at 37°C 1 drop (0 025 ml) of 20% thrice washed rabbit red blood cells was then added to each tube, and the tubes were placed in the 37°C water-bath for one hour The end-point was taken as the last tube showing lysis of any degree

Standard antitoxin, diluted to contain 0 5 international units (I U), was used as a control and a method of calibration in each batch of tests

Results

240 sera from 70 patients with infection of the lower respiratory tract, including 19 with proved influenza A, 100 sera from apparently healthy people, 26 sera from persons with superficial staphylococcal skin lesions, and 6 sera from patients with severe non-respiratory staphylococcal lesions were examined by this method Tables I and II show that in the 70 patients with infection of the lower respiratory tract, except 4 in whom there was no detectable antibody, the levels of circulating antitoxin ranged from 0 2 to 3 2 I U per ml, and that the distribution was similar to that in the group of 100 healthy people and 32 persons with non-pulmonary staphylococcal lesions

The 4 patients in whose serum there was no detectable antibody were those who had severe combined influenzal and staphylococcal infections 2 of the patients died but in the 2 survivors circulating antibodies developed within a week of admission to hospital (table II) At no time was free toxin found in the circulation of these patients No change in titre of the circulating antibodies to α-lysin was detected in the weekly serum specimens in any of the other 66 patients with infection of the lower respiratory tract

In healthy persons circulating antibodies to the staphylococcal α hæmolysin range from 0 2 to 2 0 units (mean about 0 7 unit) (Seeley et al 1944, Widholm 1951, Marks 1953) In cases of staphylococcal infection of the skin the antibody often remains at the normal level, but when the lesions become chronic it may rise to 8 or more units per ml We have not been able to discover any published instance, or any other instance in our own observations apart from the 4 cases recorded here, in which the antibody titre was below a detectable level at any time

Discussion

It is clear from our own experience and that of others that staphylococcal invasion of the lower respiratory tract in adults, producing severe and often fatal illness, is practically limited to the time of influenza epidemics On occasions it has assumed epidemic proportions with a very high fatality-rate Several workers have recently drawn attention to the different ways in which staphylococcal pneumonia can occur in association with influenza, and these reports have to some extent corrected the over-emphasis on the case fatality In most patients definite evidence of the association of staphylococcal and influenzal infection is wanting, and much work is needed before the degree of association of virus and staphylococcal infection can be assessed

Further investigation is also needed to determine whether the strains of *Staph aureus* or of the influenza virus causing this illness, particularly in its fulminating form, have any special virulence or toxigenicity The work done by Williams et al (1953) suggests that staphylococci of a particular bacteriophage type are significantly associated with the fulminating infection, but this awaits confirmation, and nothing has been recorded of any other special characteristic

The exact role of virus and staphylococcus in producing the lung lesions is far from clear Most workers agree that the staphylococcus grows and flourishes in the bronchial tree where the epithelium has been damaged by a preceding or co existing infection with influenza virus This presumably applies also to the relation between *Strep pyogenes* or *H influenzæ* and the influenza virus, because it is clear from published accounts that pneumonia attributed to these organisms at the time of influenza epidemics is in many cases indistinguishable clinically or pathologically from that caused by *Staph aureus* (Dwinnell 1919, Tytler et al 1919, Winternitz et al 1920, Wollenman and Finland 1943) It is not clear whether these bacteria are present fortuitously or transmitted in association with the virus

It is striking that the 4 patients in whom there was no detectable antibody to staphylococcal α hæmolysin during the acute phase of the illness had severe pneumonia in which influenza A and *Staph aureus* coexisted This suggests that the circulating antibody had been neutralised by the toxin produced as a result of the massive infection of the lower respiratory tract with staphylococci

Finally, in view of the low levels of staphylococcal antitoxin in the serum of these 4 patients, we suggest that, in addition to antibiotics, staphylococcal antitoxin may be of use in treatment if given at an early stage and in adequate dosage

Summary

Of 70 patients with infection of the lower respiratory tract 4 had combined infection by *Staph aureus* and by influenza-A virus, 2 of them died

In these 4 patients the normal circulating staphylococcal antibody to α hæmolysin appeared to have been completely neutralised by toxin produced in the lungs

372 specimens of serum, including 32 from patients with other staphylococcal conditions, were examined for antibody to staphylococcal α-hæmolysin In none of these was the antibody titre below the normal range

The association of *Staph aureus* and influenza virus in the causation of severe and often fatal pneumonia is reviewed

We wish to thank Prof Harold Scarborough and Prof Scott Thomson for advice and criticism

Lymphosarcomatosis

The disease was arrested in 3 of 5 cases, but no sign of improvement was noted in the 2 others One of the patients, whose course of treatment ended six months ago, is back at work and needs no further treatment

Hodgkin's Disease

In 6 of 14 cases of lymphogranulomatosis we obtained excellent results the lymph-glands became smaller and the pyrexia disappeared In 4 other cases the results were favourable, but the remaining 4 patients died before the course of treatment was completed

Carcinoma

We tried B C M on 40 patients with cancer of the lung, in 20 of them the pain became less and the general condition easier, and a few put on weight We also tried B C M on 28 patients with non-pulmonary cancer In 1 of these inoperable cancer of the pancreas was found at laparotomy, after a course of B C M his vomiting, abdominal pain, and diarrhœa ceased and he went back to work A woman with ovarian cancer lost some of her metastases and is now being treated as an outpatient

CONCLUSIONS

B C M is apparently active against many malignant disorders, but especially against tumours of the lymphoid system Its special advantages are low toxicity and the fact that it may be administered to outpatients

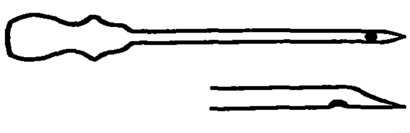
MODIFIED INTRAVENOUS-DRIP NEEDLE

Anyone who has had to set up an intravenous-saline infusion or blood-transfusion at all frequently must have had the annoying and worrying experience of seeing the drip stop, owing to the bevel of the needle coming up against the vein wall and thus becoming obstructed Commonly this can be corrected by arranging a small wad of cotton-wool under the junction of the needle hub and rubber tubing but the obstruction is liable to recur and give trouble, particularly in operation cases where the site of entry of the needle into the vein is covered by sterile towels, and is thus relatively inaccessible

The accompanying figure shows a standard blood-transfusion needle slightly modified to overcome this difficulty A hole is bored through the needle near its tip on the side away from the bevel If the bevel of the needle now comes to lie flat against the wall of the vein, the drip fluid is free to enter the vein via this alternative opening



This modified needle has been used by me for some months in the operating theatres here It presents no additional difficulties when it is introduced into a vein I have not yet had a case when using it where the drip has stopped owing to obstruction by the vein wall

The modification can be effected by any competent hospital-workshop technician The edges of the bored hole should be smooth, to discourage formation of adherent blood-clot round it

The work has kindly been done for me at the Radcliffe Infirmary in the workshop of the Nuffield department of anæsthetics by Mr R Salt and Mr R Corney

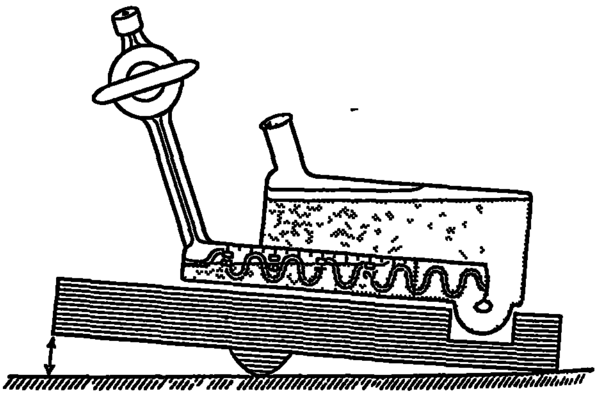
AN OXYGEN ANALYSER

There is need for an oxygen analyser simple enough to be used by a nurse If such an instrument were available, the routine measurement of oxygen concentration in tents and incubators—obviously a desirable procedure—would probably become more generally practised Instruments depending on the magnetic properties of oxygen are costly, and those using a chemical absorbent have hitherto proved insufficiently reliable for routine use in hospitals

The instrument here described makes use of a chemical absorbent, 1 2 4-triacetoxybenzene (1 2 4-triacetylhydroquinone), which, unlike the agents previously in use (pyrogallol, hydrosulphite, and chromous salts), both absorbs oxygen rapidly and retains this property for a long time [1]



A horizontal glass tube of about 5 ml capacity is connected at one end by a short U-tube to a reservoir, the other end opening into a capillary tube with a tap A glass spiral is incorporated within the horizontal tube When the tap is opened, the absorbent fluid in the reservoir fills the horizontal tube and the capillary tube to a level just short of the tap The tap is closed, and the instrument is ready for use A layer of paraffin oil introduced into the reservoir will float on the surface of the absorbent fluid and prevent access of air to the latter

A sample of the gas to be analysed is withdrawn in a syringe, whose nozzle is connected by a short rubber tube to the tap, which is then opened A measured 3 ml of gas is delivered into the tube, after which the tap is closed

The instrument is mounted on a wooden stand fitted with a rocker, enabling the instrument to be rocked through a small arc on either side of the horizontal In this way the bubble of gas can be moved from one end of the tube to the other Absorption of oxygen is also facilitated by the glass spiral, which greatly enlarges the surface of fluid presented to the gas bubble as it traverses the tube When absorption is complete (a matter of about half a minute) the instrument is held vertically with the tap uppermost The level of fluid in the tube then registers the amount of gas absorbed, the tube being calibrated to allow the percentage of oxygen in the sample to be read off directly The whole procedure occupies less than a minute

1 2 4-Triacetoxybenzene (British Drug Houses Ltd) is used in 10 % solution in 15 % KOH Recharging of the instrument is required infrequently since one fill (10 ml) is good for several hundred analyses

The instrument is made by Camlab Glass Ltd 50a Burleigh Street Cambridge

Time before discharge of patients with paronychia

A, 30 patients, aged 14 or over, submitted to combined surgical and physical treatment, without local aureomycin powder

B, 88 patients, aged 14 or over, submitted to combined surgical and physical treatment with local aureomycin powder

C, 23 patients, aged 13 or less, submitted to combined surgical and physical treatment with local aureomycin powder

D, 33 patients, aged 14 or over, treated by surgery and proflavine dressings only

The control series of 33 patients over 14 years of age (group D) treated by surgery and proflavine dressings were discharged after an average of 8 0 days

These results are summarised in the accompanying table and figure

Discussion

Patients treated by combined surgery and physical treatment (groups A–C) were discharged, on an average, three days before the group treated by surgery and proflavine dressings alone (group D) This confirms our clinical impression that in all types of superficial sepsis treated by combined surgery and physical methods, the results compared very favourably with treatment by surgical routines alone, in regard to speed of resolution of the lesions In the largest group (B) of 88 adult patients treated with combined surgical and physical treatment and application of starch powder containing 2% aureomycin, the average time of 5 3 days is longer than that for the group (A) of 30 adult patients treated in the same way but without local application of the powder We feel that the probable explanation of this slight difference was that the group B were more severely infected locally, with much pus present, and the aureomycin powder was used for this reason

The small group (C) of 23 children had very rapid resolution after surgery and physical treatment, some being discharged after two or three days The favourable factor in such cases is almost certainly the small area of the nail-bed involved, even though the young age group tended to soil dressings and the wound area to a much greater extent than did adults

The results indicate that, in cases of acute paronychia of the hand digits, treatment by surgery combined with physical methods leads to more rapid resolution of the lesion, and earlier return to normal work

RESULTS OF TREATMENT OF PARONYCHIA

Group	Age (yr)	No of patients	Nail removed	S W D twice daily	Local U V light	Local aureomycin powder	Average duration before discharge (days)
A	14 –	30	Yes	Yes	Yes	No	4 3
B	14 –	88	Yes	Yes	Yes	Yes	5 3
C	13 or less	23	Yes	Yes	Yes	Yes	4 1
D	14 –	33	Yes	No	No	No	8 0

S W D = short wave diathermy
U V = ultraviolet

Summary

141 consecutiv cases of paronych of the hand digi were treated b surgical removal (the nail combine with subsequent trea ment by physica methods

A control group (33 consecutive case were treated by surg cal removal of th nail only and dressing of 1 in 1000 proflavin hemisulphate

In the combinec treatment group ther was an average savin of three days in tim of disability befor discharge withou dressings and fit fo work

Our thanks are due to Mr R H Boggon, consultant i charge of the casualty department, St Thomas's Hospita for permission to report these cases and to the physic therapy staff who treated the majority of patients in th series

WE have previously reported our experiences wit long-term oxytetracycline (terramycin) in advance chronic respiratory infections (Helm et al 1954) W describe here the later progress of these patients

Results

Chronic Staphylococcal Bronchopneumonia

Case A —This 4-year old girl with fibrocystic disease o the pancreas and staphylococcal bronchopneumonia remained greatly improved and led a normal life while oxytetracycline was administered but relapsed rapidly when administration was interrupted Her condition was maintained for nearly 3 years, but towards the end of this time resistant staphylo cocci began to appear in increasing numbers in her sputum, and, although the antibiotic still appeared to be essential for her survival, her condition began to deteriorate with recurrent

The design of the experiments was complicated but consisted broadly in treating anxiety as the independent variable in the first experiments, and in treating initial hippuric acid level as the independent variable in the second set of experiments Hippuric acid was chosen because earlier work by Dr Persky had shown that patients with free anxiety had a high hippuric acid excretion after intravenous injection of sodium benzoate

The investigation did not yield clear cut results Hippuric acid excretion, on which much of the work turned, was not higher in those who were judged to be under the greatest stress Glutathione level, however, dropped at times of severe stress, the maximum fall occurring ten hours after the stress In accounting for these unexpected findings, the authors emphasise their psychological observation that not only fear of physical harm through jumping but also fear of being shamed through failure played an important part in the man's anxiety this distinguished them from patients with anxiety, in whom high hippuric acid excretion had been found The psychological tests indicated that stress impaired the performance of tasks requiring perceptual discrimination and memory, but that a "stress tolerance test" which involved the response to vivid pictures of threatening events (such as falling with an unopened parachute), did not help to measure anxiety *In general, the biochemical findings discriminated* more effectively than the psychological ones

Though the work is presented in a wordy difficult form, it is a valuable and instructive attempt to observe under fairly rigorous conditions the changes that accompany an undeniable stress in real life

Atlas of Rœntgen Anatomy of the Skull

LEWIS E ETTER, M D, F A C R, assistant professor of radiology, school of medicine, University of Pittsburgh, Pennsylvania Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1955 Pp 215 £5 6s

USING a disarticulated skull with one bone at a time either removed or marked, Dr Etter gives a convincing demonstration of the part played by each bone in forming the radiographic image Most of the conventional projections are illustrated and described The book also includes Dr J B Farrior's material on the radiographic anatomy of the temporal bone, and a reprint of a paper on the skull of the newborn infant by Dr S Henderson and Dr L S Sherman

Most of the illustrations are clear, though not everyone will like the "new visual aid consisting of cutouts of the radiographs," when used for illustrating a book A black background, as used for many of the photographs, with white lettering would have been better Many of the illustrations would have been clearer had they been larger, even at the expense of the size of lettering used for the labels

Radiologists will find this collection convenient to use and few will be familiar with all it has to offer It will form a very useful work of reference, and, since the proof of its assertions is presented, a convincing arbiter of dispute

Moto-Kinesthetic Speech Training

EDNA HILL YOUNG and SARA STINCHFIELD HAWK Stanford Calif Stanford University Press London Oxford University Press 1955 Pp 176 40*s*

MRS Young and Dr Hawk have revised their earlier work, *Children with Delayed or Defective Speech* in the light of further research, and have produced a valuable textbook on speech training and speech rehabilitation What does "moto-kinesthetic" mean? The "moto" part is the teacher's use, in the three "dimensions" of place time, and direction, of pressure by the fingers on lips, jaw nose, throat, and waistline to induce the child to modify the air current so that desired sounds shall be produced Simultaneously, auditory and visual stimuli are offered The dust-cover depicts a teacher stimulating "shoe" with her right hand on the child's upper lip and jaw, while she shows him a picture of a pair of boots and says "shoe" He lies "relaxed on the speech table" while he learns by kinæsthesia feeling the actions and positions associated with the sound

In part I, Mrs Young concludes by stressing the need for research to show "*the facts relative to early muscular learning as affecting later speech*" It is obvious that her personal experience of a speech handicap has helped her to present with clarity and vision the moto kinesthetic technique In describing this method of sound stimulation, she first emphasises the need to understand fully the function of the air current as the basis of speech, and the way normal speech development may need encouragement to avoid subsequent defects

The book includes pictures illustrating the finger movements used to stimulate the enunciation of vowels and consonants Mrs Young does not suggest that her method is to be used exclusively for all problems, but she shows how it may be adapted to help even the more heavily handicapped such as the deaf, the blind, the cerebral palsied the aphasic, and the stutterer

In part II, Dr Hawk gives a careful analysis of speech disorders and describes the examinations and tests which have been used, and the conclusions drawn

How interesting will this book be to most medical doctors? To most, not very, to a few, absorbing while to those who see many children handicapped in all sorts of different ways it will be something to dip into now and again It will leave them feeling how much more they could do if they had the time, if they had not (in James Hilton's phrase) "the knack of putting first things second," as they hurry a patient in order not to keep the next one waiting

---

Postgraduate Obstetrics and Gynæcology (2nd ed London Butterworth 1955 Pp 688 70*s*)—The first edition of this book appeared in 1950 and was based on the extremely popular postgraduate lectures given by Prof F J Browne in the years after the late war The text has now been revised, and father and son (Prof J C McClure Browne) combine to give the benefit of long years of experience and of more recent views The length of the book has been increased by some 35% although only a few new chapters have been added, and the policy is still to avoid repeating what is covered in the authors' book *Antenatal and Postnatal Care* Because of its origin the book is a series of essays rather than a standard text Each subject is treated in a readable yet authoritative way The illustrations and particularly the photomicrographs are excellent The reputation already enjoyed by this book will be enhanced by this new edition, and it will win new friends among postgraduate students and practising obstetricians and *gynæcologists*

Operative Technic in General Surgery (2nd ed Vol I New York Appleton Century Crofts 1955 Pp 973 $20) —The greater part of the first volume of this work (edited by Prof Warren H Cole, of the University of Illinois) is devoted to the surgery of the abdomen, which is dealt with authoritatively by acknowledged experts By contrast with the more coherent gastrointestinal section, the rather random order of subjects in the remaining chapters makes the volume uneven The endocrine glands suffer from separation, the thyroid and parathyroid joining company in one chapter, while the adrenals come as an afterthought to the pancreas and the thymus has got lost altogether Orthopædics receives its quota in chapters on amputations, on muscles fascial tendons, and bursæ, and on the hand and its tendons, but bone is excluded There is a chapter on the breast, while another on skin and subcutaneous tissue is thrown in for good measure (burns having been earlier considered on their own) without mention of plastic surgical technique Reliance is rightly placed on illustrations, which are variable in quality

Radium Therapy (2nd ed London Baillière, Tindall & Cox 1956 Pp 286 37*s* 6*d*)—Since the 1945 *edition of* this book by Mr C W Wilson, PH D, principal physicist to the Westminster Hospital London immense strides have been made in the field of radioactive isotopes, and the physical aspects have been incorporated in the new edition But radium therapy still remains the basis of the book Dr Wilson is to be congratulated on again producing an up to date and essentially practical book which is a 'must' for hospital physicists, radiotherapists, and students in need of a reliable basic text treatment could only be continued in fourteen (one with chronic staphylococcal bronchopneumonia nine with chronic bronchitis four with bronchiectasis) These are the patients whose subsequent course is reported here Only eight are still receiving the antibiotic, the duration of treatment ranging from $2^3/_4$ to $1^1/_2$ years In two other bronchitics, although progress was favourable, treatment was stopped in an attempt to prepare an autogenous vaccine

The ultimate death of the child with fibrocystic disease of the pancreas was presumably inevitable, since the staphylococcus fairly readily becomes resistant to antibiotics Nevertheless it does seem that her life was prolonged for some 3 years by continuous oxytetracycline

As regards the patients with chronic bronchitis and bronchiectasis, the original infecting organism was known to be *H influenzæ* in each instance Unfortunately, regular accurate estimates of the sensitivity of these organisms to oxytetracycline were not made but such information as we have indicates that resistance does not develop rapidly It is of considerable interest that one patient with bronchitis, whose response had been highly satisfactory for nine months, relapsed rapidly after a fortnight's interruption of treatment and subsequently failed to respond as well In this case a strain of *H influenzæ* isolated after a further 10 months' treatment was resistant to oxytetracycline From observations on other patients not included in this series we have the impression that it is often more difficult to obtain a satisfactory response if treatment is interrupted in this way than if it is continued without a break In addition as in the patient mentioned, we have seen others whose infection relapsed rapidly when therapy was discontinued, even if it had previously been given for many months This accords with the observations of Knox et al (1955) in patients treated for several months with antibiotics administered by aerosol These relapses are perhaps not surprising since *H. influenzæ* was isolated on occasion from several of our patients during chemotherapy indicating that the infection was not eradicated but merely suppressed

It is probable that the maintained benefit in these patients is due not only to the suppression of *H influenzæ* but also to the prevention of recurrent acute pneumococcal infections which are so common in the absence of chemotherapy In no instance in this series have pneumococci been isolated from the sputum of patients while on treatment and, since this organism appears unlikely to develop resistance, it is reasonable to hope that this effect at least may remain so long as treatment is continued

Although we feel that deterioration probably will occur ultimately, owing to development of resistant strains of *H influenzæ*, this has not yet occurred definitely in any case where treatment has been maintained without interruption How long treatment can be continued with benefit is still therefore a matter for conjecture and will probably be found to be variable and unpredictable There is no doubt however, that some patients are greatly benefited for long periods

Summary

A follow-up report is described of patients receiving long-term treatment with oxytetracycline for chronic non-tuberculous respiratory infections

Eight patients have remained on treatment with benefit to the present time for periods ranging from $2^3/_4$ to $1^1/_2$ years

A NEW OPERATION FOR THE CONSTRUCTION OF AN ARTIFICIAL FALLOPIAN TUBE

R G Cross
M.D, M A O NUI, F R C.P I, M R C O G
PHYSICIAN I/C INFERTILITY DEPARTMENT, ROTUNDA HOSPITAL DUBLIN, GYNÆCOLOGIST, BON SECOURS HOSPITAL, DUBLIN

C A Erskine
M.A, Ph D Dubl, M.R C P I
PROFESSOR OF HUMAN ANATOMY AND EMBRYOLOGY IN THE UNIVERSITY OF DUBLIN

The theoretical basis for the operation described here is derived from embryological observations on the common origin of the peritoneum, the uterine tube, and the ovary The procedure consists of making an opening in the uterus, lining this opening with peritoneum, and utilising the round ligament and local peritoneal tissue in the construction of the tube

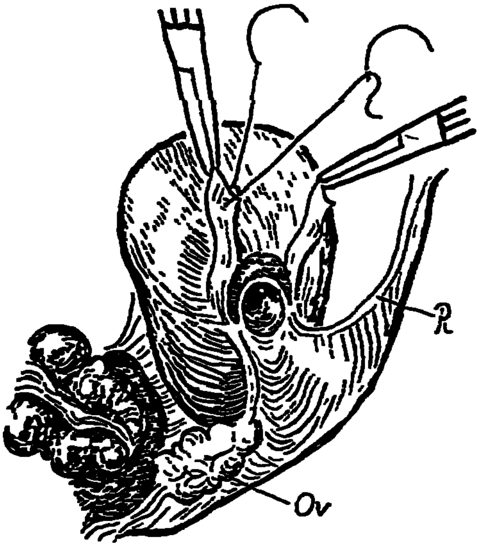

Fig 1—Peritoneal flaps raised around reamed aperture in uterus R round ligament, Ov ovary

Technique

The peritoneal cavity is entered through a median subumbilical incision The ovary, round ligament, and ovarian ligament on both sides are identified, and the uterus is pulled up

With a Green-Armytage reamer (9 mm) an opening is made into the uterine cavity at the site of the interstitial part of the tube, two flaps of peritoneum are fashioned from the anterior and posterior aspects of the uterus around the reamed aperture (fig 1) The free margins of these flaps are transfixed with a fine suture of 00 chromic catgut and by the Sturmdorf technique, the peritoneal flaps are drawn towards the uterine cavity thereby providing a peritoneal lining for the aperture reamed in

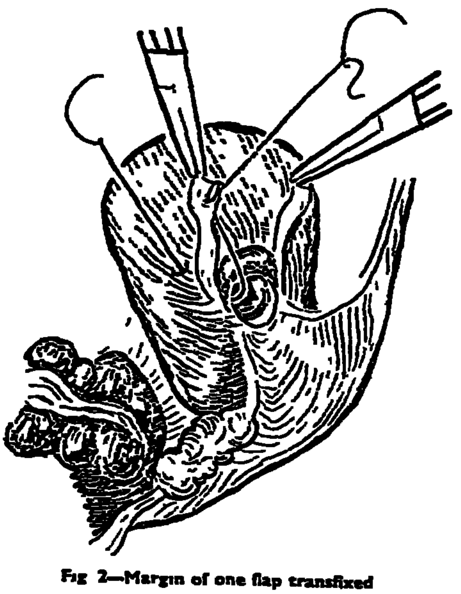

Fig 2—Margin of one flap transfixed

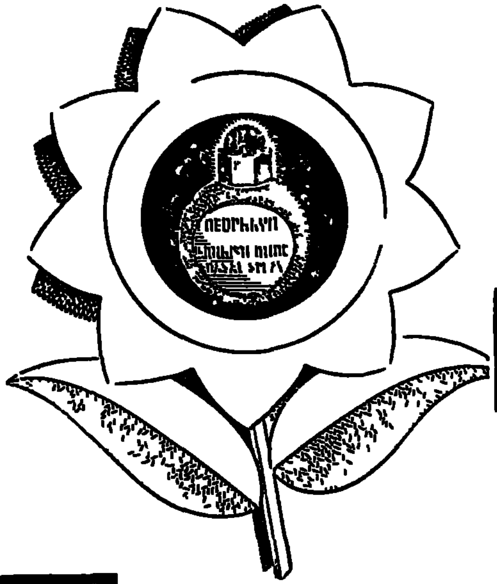
Symptomatic relief in hay fever, allergic rhinitis



In hay fever and allergic rhinitis NEOPHRYN WITH ANTIHISTAMINE nasal spray relieves nasal congestion and reduces local irritation and sneezing There is no C N S stimulation or harmful effect on the mucous membrane and secondary congestion is rare,

Neophryn is also available without antihistamine, for simple decongestion It is supplied as a spray, or as drops

CLASSIFICATION OF CARCINOMA OF BRONCHUS

Source	Bryson and Spencer (866 cases)	Walter and Pryce (1[illegible]9 cases)	Present series (171 cases)	
			Initial	Corrected for mucin production
Oat cell (%)	36.0	37.1	35.7	35.7
Adenocarcinoma (%)	4.9	28.3	15.8	22.8
Squamous cell (%)	6.9	20.1	27.5	27.5
"Squamoid" (%)	11.2	Nil	Nil	Nil
Polygonal cell (%)	40.2	10.7	21.0	14.0
Rejected (poor histology &c.) (%)	0.8	3.8	Nil	Nil

cell," or "squamoid" cancers. The term "squamoid" was used by Bryson and Spencer and is admirably descriptive; they used the term "polygonal" for the residue of undifferentiated carcinomas.

We eliminated the "squamoid" group and included all non-differentiated cancers in the polygonal cell group. It is obvious that this group must include anaplastic squamous cell and anaplastic adenocarcinomas, and we therefore tried to reduce the proportion of growths classified as "polygonal-cell" by demonstrating criteria by which they might be allocated to the squamous-cell or adenocarcinoma groups.

Variability of cell type is a feature of lung cancer (Willis 1948) and may be caused by metaplasia, which occurs commonly in adenocarcinomas and occasionally in oat cell tumours; it must be distinguished from differentiation in a predominantly anaplastic carcinoma. Areas of squamous metaplasia are common in small bronchi which are chronically inflamed and such bronchi may be included in the growth. It is also possible that, in some instances, a genuine mixed tumour results from the fusion of foci of differing cell types; we encountered 1 tumour of this nature in which large areas of squamous and oat-cell carcinomas were mixed. Cancer cells, of whatever type, often have a tendency to line spaces, and the lung alveoli provide an excellent basis for this pseudo adenomatous extension. This, however, is not true tubule formation and such tumours are not necessarily adenocarcinomas.

Our initial classification was:

(1) *Squamous cell carcinoma.* 'prickles' or keratin demonstrated; no oat cell or tubular growth.

(2) *Adenocarcinoma.* true tubular and mucinous cancers.

(3) *Oat cell carcinoma.* there is no difficulty about these, although, as well illustrated by Walter and Pryce (1955), half of them contain characteristic tubular structures.

(4) *Polygonal cell carcinoma.* these form a large residue and have none of the above characteristics.

The material analysed was obtained from necropsies; some of the growths were small and were studied by serial or interrupted serial sections. The study of secondary tumours, when present, shed some light in doubtful cases. The results are shown in the accompanying table; so far as the oat cell growths are concerned, our figures closely agree with those of Bryson and Spencer and Walter and Pryce. Certain factors undoubtedly influence the figures (e.g., cases considered operable were transferred elsewhere), but, allowing for these, there is still disagreement between the figures for the polygonal-cell group: in the initial classification of our series, 21% of the carcinomas were of the polygonal cell type, as compared with 40.2% recorded by Bryson and Spencer and 10.7% recorded by Walter and Pryce. Our figures for polygonal-cell carcinoma were undoubtedly raised by the discovery at necropsy of a number of small, unsuspected growths associated with lung scars (Raeburn and Spencer 1953); but "polygonal" is another way of saying "unclassified," and it is therefore desirable to diminish this group by any legitimate means.

Sections of all the tumours and of their secondary deposits in the polygonal cell group were stained for mucin; of the 36 tumours examined, 12 contained mucin and were therefore considered to be adenocarcinomas. In 10 cases there was copious mucin production; in the remaining 2, careful search revealed mucinous areas. A number of these tumours contained occasional small, cubical, strongly mucinous cells (unicellular remnants of destroyed mucous glands) which were easily distinguishable from carcinoma cells. 1 tumour which contained mucin in most of its cells looked very like a squamous cell carcinoma although true squamous characteristics were absent.

The corrected figures for the present series, after the growths had been stained for mucin and those containing mucin had been transferred to the adenocarcinoma group, are also shown in the table; the corrected figures for adenocarcinomas rose from 15.8 to 22.8%, and those for polygonal cell carcinomas fell from 21 to 14%.

Summary

Mucin can be demonstrated in some "polygonal-cell" carcinomas of the bronchus. These growths should be regarded as adenocarcinomas, and the residue of unclassified cancers will thus be diminished.

This work was aided by a grant from the British Empire Cancer Campaign.

ARTIFICIAL SPONGES IN SURGERY

BRYAN WILLIAMS
M.D. Edin., F.R.C.S.E., F.R.C.O.G.
SENIOR OBSTETRICIAN AND GYNÆCOLOGIST, MIDDLESBROUGH
MATERNITY AND NORTH ORMESBY HOSPITALS, YORKS.

> "Only those surgeons who have operated without gloves and with soft marine sponges instead of gauze swabs can have enjoyed the pure delight of operating."—Grey Turner (1943).

FOR some time I have been using artificial sponges in obstetrical and gynæcological work. They are cellulose sponges made from wood pulp by the viscose process and marketed under the name 'Spontex'. When moistened they are soft, and they are highly absorbent. They can be easily washed after use and stand repeated boiling and autoclaving. Tests made by Dr. R. Blowers, director of the Public Health Laboratory (Medical Research Council), Middlesbrough, show that after autoclaving they are sterile both on aerobic and anaerobic culture. The material can be cut quite easily when dry, and various sizes of sponge have been tried. It has been found convenient to use a large size, about 3½ × 2½ × 1½ in., which will absorb about 4 oz. of water, and a smaller oblong size which can be held in a sponge forceps.

A great advantage of using these sponges lies in the resulting simplification of the swab count. It is possible to do a cæsarean section with only four large sponges in addition to the gauze ones used for skin preparation and the baby. The intraperitoneal part of a hysterectomy can be done with four small swabs; and the repair of the perineum or an episiotomy after delivery, which often needs the use of a considerable amount of gauze or wool if there is much bleeding, can be done with one or two small ones.

Another advantage of using the larger sponges is that, owing to their absorbing power, they are very effective in removing large amounts of fluid if a sucker is not available. Probably the regular use of such sponges in surgery would be an economy, because gauze is an expensive item in hospital budgets and may account for a third of the total cost of all dressings. These sponges myelitis, and all occurred during or shortly after the seasonal period of prevalence of poliomyelitis. The three British outbreaks [18 24 25] were in late summer, in contrast to the former peak incidence of encephalitis lethargica in the first three months of the year.[2] Five outbreaks took the form of dramatic localised epidemics, four of which were in nurses' homes. Dr RAMSAY and Dr O'SULLIVAN describe cases in the neighbourhood of one of these outbreaks, and HILL [17] had a similar experience in Durban. The attack-rate in closed communities is high. The onset in this group is usually acute with systemic prodromata such as are common in poliomyelitis. In contrast, fever is usually low and may be absent.[14 18 25] The course is generally two to eight weeks but occasionally symptoms may last for months. Relapses are frequent. Usually the immediate outcome is favourable but in a few cases paresis or mental sequelæ may be incapacitating for many months.[22 23 26] Depression, emotional lability, or irritability in convalescence have been a constant feature in all group-II outbreaks. Although previous experience has shown that a long period of observation will be necessary before the harmlessness of the disorder is assured, it can at least be said that the immediate mortality-rate of nil is in striking contrast to the epidemic infections of the nervous system previously described[4], and this in itself is very encouraging.

Among the more characteristic features of group II are the severe muscular pains, often accompanied by exquisite tenderness, which often dominate the clinical picture.[22–25] As WHITE and BURTCH [23] have pointed out, these pains differ from those of poliomyelitis in that they are not simply a short-lived precursor of paresis but may last for weeks. Most commonly they affect the neck, back, or limbs but there may also be Bornholm-like chest and abdominal pains.[17 18 23 25] Continuous or intermittent painful muscular spasms were noted in the outbreaks at the Middlesex and Royal Free Hospitals, and they are also reported by Dr RAMSAY and Dr O'SULLIVAN. In nearly every patient there are symptoms or signs of disease of the central nervous system, but the weight and site of the damage vary considerably from outbreak to outbreak. The Hampstead and Berlin epidemics illustrate this variation. The innervation of the eye muscles (diplopia and nystagmus) and the seventh and eighth cranial nerves (deafness, hyperacusis, vertigo, and facial weakness) suffer most commonly. Sensory symptoms and signs are common and pyramidal signs have also been observed. Some patients in Adelaide and Durban and at the Middlesex Hospital had retention of urine. The paresis, usually short-lived but occasionally persisting for weeks or months, is in itself an interesting problem for in many cases it is not accompanied by the classical disturbances of tone and reflexes which would point to damage in the anterior horn or pyramidal tract.[23 25 26] Pain, muscular spasm, and involuntary movements often make the degree of palsy difficult to assess. In this connection the striking electromyographic records obtained by Dr RAMSAY and Dr O'SULLIVAN are of great interest. Although they do not as yet point to the exact nature of the lesions, they may provide evidence of organic paresis in patients who might otherwise be suspected of hysteria, and in a disease at present so bereft of positive laboratory findings they may be a help in diagnosis in the future.

The outbreaks mainly differ in the severity and site of the damage to the nervous system but the lymph glands are another point of difference. Enlarged lymph glands, particularly in the posterior cervical triangle, were prominent in the Hampstead and Royal Free cases, and they were also noted in 4 cases by WHITE and BURTCH [23] and in the more doubtful Cumberland outbreak.[21] In retrospect lymphadenopathy was found to have been present in 2 of the 14 cases reported from the Middlesex.[27] Hepatitis and splenomegaly may also turn out to be part of the picture. It is doubtful whether the absence of these features in the other reports can be attributed entirely to observer error [27] and it must be accepted as a real discrepancy.

A study of the available material in group II shows sufficient common ground to suggest that this is a new clinical entity which may be expected to appear again here or elsewhere in the late summer and autumn. From the purely practical standpoint it would be useful to have a name for this syndrome. As the most helpful single feature in the recognition of this syndrome in the past has been the predominantly normal cerebrospinal fluid, the names which have already been suggested, "Iceland disease" [16 23] and "Akureyri disease," are not really appropriate. The objections to any but a purely descriptive name for a disorder without a known cause or established pathology are obvious. For this reason, the term "benign myalgic encephalomyelitis" may be acceptable. It in no way prejudices the arguments for or against a single or a related group of causal agents, and it does describe some of the striking features of a syndrome characterised by (1) symptoms and signs of damage to the brain and spinal cord, in a greater or lesser degree, (2) protracted muscle pain with paresis and cramp, (3) emotional disturbances in convalescence, (4) normal C.S.F., (5) involvement, in some variants, of the reticuloendothelial system, (6) a protracted course with relapses in severe cases, and (7) a relatively benign outcome. It remains to identify this syndrome more precisely, but we believe that its characteristics are now sufficiently clear to differentiate it from poliomyelitis, epidemic myalgia, glandular fever, the forms of epidemic encephalitis already described, and, need it be said, hysteria.

Antibiotic-resistant Staphylococci

IF bacteriologists are good judges of what is important, the direction and emphasis of much of their work suggests that it is high time we adopted whatever modifications of clinical practice are necessary to halt the spread of antibiotic-resistant staphylococci in hospital wards and outpatient departments. These infections in hospital are not only a cause of ill health, lost time, and wasted money, but also a source from which a veritable epidemic of staphylococcal infections may spread to the general community. There is no reason whatever to doubt the implications of ROUNTREE and RHEUBEN's [28] evidence that in December, 1955, 25·7% of 101 nasal carriers of staphylococci among 200 Sydney blood donors

[28] Rountree P M, Rheuben J. *Med. J. Aust.* 1956, i, 399.

She also became mildly sensitive to penicillin in 1954 and had ceased giving this

From October, 1955, she has injected streptomycin from the cartridges, giving up to 20 g daily with no untoward effects

Discussion

In these 2 cases the clinical picture was that of contact dermatitis due to streptomycin In published cases the most common sites have been hands, arms, face, eyes, and eyelids, in that order Case 2, with an interval of five years before sensitisation, shows clearly that long periods without trouble from handling streptomycin do not necessarily signify immunity, and is in striking contrast to case 1, who became sensitive on first contact Previously published cases have also shown widely varying intervals, from first contact to five years, before sensitisation

It cannot be claimed, on the basis of only 2 cases, that the incidence of streptomycin sensitivity could be very greatly reduced, but the present cases seem to suggest that this may be so and that it would be advisable to conduct further trials, particularly on the already sensitised Then, if it is confirmed that sensitised nurses can continue to give injections by this method, the method should also be used to prevent contact sensitivity Care, however, should be taken that the ease of this method does not lull nurses into neglecting the aseptic precautions that should accompany the injection of antibiotics

Summary

A "no touch" technique for injecting streptomycin from prepared cartridges is described

2 nurses with streptomycin dermatitis were enabled by this technique to return to giving streptomycin

Streptomycin sensitivity is a serious handicap and a possible danger to nurses, and the cartridge method of injection should be used to prevent contact sensitivity and enable those sensitised to use streptomycin again

The sterile cartridges ('Viules') containing streptomycin were supplied by Boots Pure Drug Co Ltd

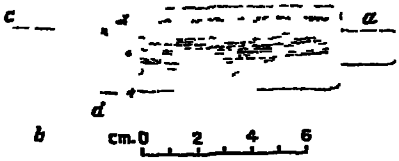
HUMIDIFIER FOR USE WITH TRACHEOTOMY AND POSITIVE-PRESSURE RESPIRATION

R V WALLEY
B.A, M B Camb
ASSISTANT MEDICAL OFFICER, HAM GREEN HOSPITAL, BRISTOL

WHEN artificial respiration is applied by positive-pressure inflation of the lungs with a cuffed tube inserted through a tracheotomy stoma, the normal humidifying and warming function of the nose and pharynx are by-passed The nose and pharynx in a healthy person warm the air to body-temperature and humidifies it to 98% saturation at that temperature (Perwitzschky 1927)



Humidifying cartridge a to patient b tory tube c, expiratory tube d rubber seal

Experience with long-continued tracheotomy has shown that inhalation of air at room temperature and humidity leads to crusting bronchial secretions Humidification is needed to prevent this Marshall and Spalding (1953) have designed and used an apparatus which warms the inspired air to 35°C and humidifies it to 100% saturation at that temperature This apparatus has an electrical heating coil and an adjustable thermostat It is of substantial size Since treatment with positive-pressure respiration already needs much complex equipment, it was thought something simpler and less bulky might suffice

Apparatus

In view of the fact that the nose and pharynx present a large surface, warm and moist, to condition the inspired air, this humidifier was designed to incorporate these features It consists of a cartridge containing a roll of silver-plated copper gauze through which the patient breathes (fig 1) The expired air, passing over the gauze loses some of its heat and moisture, which are taken up by the inspired air The cartridge, which is also warmed by contact with the body, is a cylinder of 'Perspex' 2 5 cm in internal diameter The copper gauze has a mesh of 24 to the inch and is 45 cm long and 7 5–9 0 cm broad, the greatest width being used for patients needing large tidal volumes The gauze is silver-plated to resist corrosion Stainless steel would be more resistant but not so capable of holding heat The gauze is rolled to be a tight fit in the cartridge It can be easily taken out for cleaning, which may be required on alternate days, by pulling out the rubber seal which closes one end The volume of the air enclosed by the apparatus is about 38–45 c cm according to the size used The humidifier has been used in conjunction with the Clevedon positive-pressure machine (Macrae et al 1954), the small inspiratory and large expiratory tubes being connected to one end of the cartridge The other end, with the single outlet, is joined by a plastic tube 5 cm long to the cuffed endotracheal tube The cartridge is strapped firmly to the skin in the right or left infraclavicular fossa

The performance of the apparatus was first tested by a healthy person breathing through the mouth with the nose closed by a clip The performance was later tested with a patient being ventilated with a Clevedon positive-pressure respirator

Methods

The water content of the inspired air was measured by drawing off 40–50 c cm throughout the length of each inspiration to a total of 4000 c cm from the endotracheal junction and absorbing the water with dehydrated calcium chloride, weighed before and after (Perwitzschky 1927)

Temperature was measured crudely by intermittently inserting a mercury thermometer into the inspired air-stream The figures so obtained are likely to have been lower than the actual temperature

Pressure tracings (fig 2) were taken with a drum and tambour

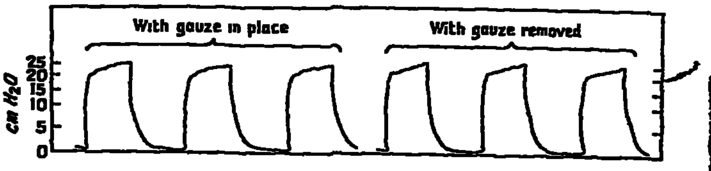


Fig 2—Pressure tracings with gauze in place and with gauze removed

effective dose, (6) bacteriological study before treatment of patients with chronic or mixed infections, (7) treatment for evidence of infection but not for the mere presence of bacteria, (8) remedy, where possible, of underlying anatomical, immunological, or metabolic defects, and (9) precautions against hospital cross-infection

Certainly it is time that we abandoned the naïve ignorance which underlies the apparently common assumption that the best thing a doctor can do for a febrile or potentially febrile patient is to "hit his bugs hard" Most of these miscalled creatures are harmless when they are left, among plenty of others of their kind, to the rich natural antibacterial resources of the human body If we were not so often and so uncritically anxious to do a bacteriological good deed where none is required, we should be far less likely to spread harm of a kind that it may soon prove impossible to control

Artificial Kidneys

SOON after the late war, various modifications of the KOLFF artificial kidney were used fairly intensively in special centres in this country, and in 1948 we reviewed this early experience[1] It was not on the whole very encouraging, and the pendulum soon swung to a conservative régime for the treatment of acute renal failure[2] [3] This can now be regarded as the standard treatment, and is in general use, with some modifications such as giving calories by vein rather than orally,[4] and delaying a rise in plasma-potassium by exchange resins in the sodium cycle[5] There seems little doubt that this practice is substantially sound, and it has saved many lives which might have been lost by ill-controlled attempts at active treatment by dialysis, which is generally recognised as requiring a trained team with frequent recourse to biochemical estimations But some recent reports of extensive work with artificial kidneys prompt the question whether we may not in this country have carried conservatism to a fault

Most of the artificial kidneys now in use follow the pattern of KOLFF, in which the patient's blood perfuses a 'Cellophane' tube round a rotating drum in a bath of suitable fluid BRUN in Copenhagen has now had long and favourable experience of a different type of artificial kidney,[6] in which blood is pumped between cellophane sheets which separate it from bath-fluid flowing in the opposite direction This apparatus has the advantage of containing a much smaller volume of blood without sacrifice of efficiency As MERRILL says, however, "the major factor in efficacy is the skill and experience of the operator and this cannot be incorporated in the design"[7] From his study of over 500 dialyses, MERRILL can speak with particular authority on the uses and limitations of the method The indications are clinical rather than biochemical, and he regards "nausea, vomiting, apathy, drowsiness and weakness" as the main evidences of 'a morbid state which cannot be relieved by the usual conservative method of management' To these, we might add uræmic twitchings and pericarditis This state of affairs is not usually reached in the first week of anuria, in civilian practice at any rate, but in traumatic surgery, with greatly increased tissue breakdown, it may appear in a day or two, and the artificial kidney was widely used in Korea, with dramatic relief of uræmic symptoms[8]

Early difficulties with the artificial kidney were largely related to disturbance of fluid and electrolyte balance, and they can be avoided by careful attention to the composition of the bath-fluid Moreover, the dialysis gives an opportunity of correcting such electrolyte disturbances as have appeared spontaneously or have been induced by evil practices such as overhydration This important function of the artificial kidney has been reviewed by HAMBURGER and RICHET[9] in the first number of a new journal, *Revue Française d'Études Cliniques et Biologiques*[10] In a series of 60 dialyses, they determined the concentration of plasma electrolytes before and at intervals after dialysis Of the cations, sodium concentration was normal or slightly reduced (others have found hyponatræmia more common in anuria, on régimes which do not restrict water intake as rigorously as that of HAMBURGER), potassium was sometimes increased, magnesium was increased more commonly than potassium, and calcium was always reduced Phosphate, sulphate, and organic acids were increased, while chloride and bicarbonate were reduced All these anomalies were altered towards normal by the dialysis, and this change was accompanied by clinical improvement "Au cours même d'application, une calme euphorie remplace l'anxieuse agitation ou la somnolence hostile de l'urémique" Faced with this complex of biochemical improvement, and adding to it the fall in blood-urea, HAMBURGER and RICHET are guarded in ascribing individual changes to specific biochemical alterations They suggest, however, that the raised magnesium concentration is related to drowsiness, and that the increase in phosphate and sulphate has not been sufficiently heeded as a cause of symptoms They claim that intestinal and peritoneal dialysis are less effective than the artificial kidney in removing phosphate and sulphate, and that these other types of dialysis are clinically less effective, in spite of a comparable effect in lowering the blood urea

As MERRILL points out, the use of the artificial kidney is based on the assumptions that it can be used safely and effectively in sick patients and that the medical state in renal failure can be improved by removal of diffusible substances from his six years experience he considers both these are justified The practical difficulty is to assemble and maintain, not the kidney itself, but a team who are competent to use it and not to abuse it Several centres in this country have now had time to appreciate both the general value and the occasional failures of conservative treatment, and some have turned to intermittent peritoneal lavage in selected cases[11] There may be a place for one or two groups to devote themselves to further study of the artificial kidney

[11] Grollman A Acute Renal Failure Springfield Ill 1954

She also became mildly sensitive to penicillin in 1954 and had ceased giving this

From October, 1955, she has injected streptomycin from the cartridges, giving up to 20 g daily with no untoward effects

Discussion

In these 2 cases the clinical picture was that of contact dermatitis due to streptomycin In published cases the most common sites have been hands, arms, face, eyes, and eyelids, in that order Case 2, with an interval of five years before sensitisation shows clearly that long periods without trouble from handling streptomycin do not necessarily signify immunity, and is in striking contrast to case 1, who became sensitive on first contact Previously published cases have also shown widely varying intervals, from first contact to five years, before sensitisation

It cannot be claimed, on the basis of only 2 cases that the incidence of streptomycin sensitivity could be very greatly reduced, but the present cases seem to suggest that this may be so and that it would be advisable to conduct further trials, particularly on the already sensitised Then, if it is confirmed that sensitised nurses can continue to give injections by this method, the method should also be used to prevent contact sensitivity Care, however, should be taken that the ease of this method does not lull nurses into neglecting the aseptic precautions that should accompany the injection of antibiotics

Summary

A "no-touch" technique for injecting streptomycin from prepared cartridges is described

2 nurses with streptomycin dermatitis were enabled by this technique to return to giving streptomycin

Streptomycin sensitivity is a serious handicap and a possible danger to nurses, and the cartridge method of injection should be used to prevent contact sensitivity and enable those sensitised to use streptomycin again

The sterile cartridges (Viules) containing streptomycin were supplied by Boots Pure Drug Co Ltd

HUMIDIFIER FOR USE WITH TRACHEOTOMY AND POSITIVE-PRESSURE RESPIRATION

R V WALLEY
B.A, M B Camb
ASSISTANT MEDICAL OFFICER, HAM GREEN HOSPITAL, BRISTOL

WHEN artificial respiration is applied by positive-pressure inflation of the lungs with a cuffed tube inserted through a tracheotomy stoma, the normal humidifying and warming function of the nose and pharynx are by passed The nose and pharynx in a healthy person warm the air to body-temperature and humidifies it to 98% saturation at that temperature (Perwitzschky 1927)

Experience with long-continued tracheotomy has shown that inhalation of air at room-temperature and humidity leads to crusting bronchial secretions Humidification is needed to prevent this Marshall and Spalding (1953) have designed and used an apparatus which warms the inspired air to 35°C and humidifies it to 100% saturation at that temperature This apparatus has an electrical heating coil and an adjustable thermostat It is of substantial size Since treatment with positive-pressure respiration already needs much complex equipment, it was thought something simpler and less bulky might suffice

Apparatus

In view of the fact that the nose and pharynx present a large surface, warm and moist, to condition the inspired air, this humidifier was designed to incorporate these features It consists of a cartridge containing a roll of silver-plated copper gauze through which the patient breathes (fig 1) The expired air, passing over the gauze loses some of its heat and moisture, which are taken up by the inspired air The cartridge, which is also warmed by contact with the body, is a cylinder of Perspex' 2 5 cm in internal diameter The copper gauze has a mesh of 24 to the inch and is 45 cm long and 7 5–9 0 cm broad, the greatest width being used for patients needing large tidal volumes The gauze is silver-plated to resist corrosion Stainless steel would be more resistant but not so capable of holding heat The gauze is rolled to be a tight fit in the cartridge It can be easily taken out for cleaning, which may be required on alternate days, by pulling out the rubber seal which closes one end The volume of the air enclosed by the apparatus is about 38–45 c cm according to the size used The humidifier has been used in conjunction with the Clevedon positive-pressure machine (Macrae et al 1954), the small inspiratory and large expiratory tubes being connected to one end of the cartridge The other end, with the single outlet, is joined by a plastic tube 5 cm long to the cuffed endotracheal tube The cartridge is strapped firmly to the skin in the right or left infraclavicular fossa

The performance of the apparatus was first tested by a healthy person breathing through the mouth with the nose closed by a clip The performance was later tested with a patient being ventilated with a Clevedon positive pressure respirator

Methods

The water content of the inspired air was measured b drawing off 40–50 c cm throughout the length of eac inspiration to a total of 4000 c cm from the endotrache junction and absorbing the water with dehydrated calcium chloride, weighed before and after (Perwitzschk 1927)

Temperature was measured crudely by intermittentl inserting a mercury thermometer into the inspired air stream The figures so obtained are likely to have bee lower than the actual temperature

Pressure tracings (fig 2) were taken with a drum an tambour

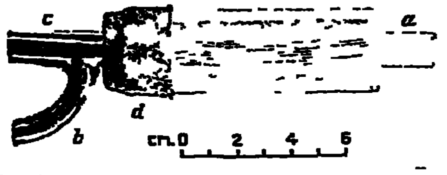

Fig 1—Humidifying cartridge a to patient b inspiratory tube c expiratory tube, d rubber seal

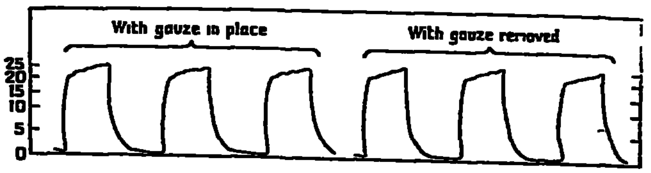

Fig 2—Pressure tracings with gauze in place and with gauze removed

When these lesions produce symptoms, discomfort in the knee often begins after a minor injury Pain and effusion are less common, and severe disability is rare "Catching" in the knee, due to the roughened patella surface, is an occasional feature (true locking indicates the presence of a loose body) Wiles et al[3] have pointed out two important physical signs pain on grating the patella against the femur, and tenderness over the articular surface of the patella, this can be elicited by displacing the patella laterally Karlson[2] attaches some importance to the presence of patella crepitus, but this sign may be misleading Radiographs are of value only in excluding other joint diseases Diagnosis should not be difficult, but associated lesions such as detachment of cartilage flakes, osteochondritis dissecans, and dislocation of the patella may also be present

Treatment may not be an easy matter When symptoms are slight, the condition tends to improve spontaneously, but rest and short-wave diathermy may help When disability is severe, the patella may be exposed and small areas of affected cartilage shaved off When there is extensive disease, either the whole articular surface of the patella may be removed or the patella itself may be excised Excision is usually indicated when the femur is also involved Although the smaller lesions usually respond favourably, the results of the more extensive operations are less satisfactory (Since these are selected cases, it is difficult to compare them with those treated conservatively) If, however, as Wiles believes, chondromalacia is a precursor of osteo arthritis, such operations may also be of prophylactic value

MR DODGSON'S MIGRAINE

WHEN he is awake, the normal person is aware of his body, its position in space, its size and shape in relation to other objects, the inter-relations of its various parts, and the continual changes in these relationships with bodily movements, or with growth and finally old age Since Paul Schilder in Vienna and Henry Head in this country elaborated their ideas of such a "body-image" or "schema," the subject has been of perennial interest to neurologists and psychiatrists The body-image is the resultant of a continuous stream of sensory impulses, both proprioceptive and exteroceptive, passing to the brain There is now much evidence from local brain lesions to suggest that these impulses are elaborated and coordinated in the posterior part of the parietal cortex in the region of the angular gyrus, which constitutes the "centre" for the body-image, but it is still a matter of argument whether the centre is represented exclusively in the non-dominant hemisphere or whether, as seems more probable *a priori*, there is some bilateral representation

This is the mechanism which mediates the normal smooth manipulation of the body in space As is often the case, the existence of such a mechanism becomes obtrusive only when its function is disordered When the body-image is severely disorganised by some gross lesion such as a vascular accident or tumour, the ensuing behaviour is bizarre To watch such a patient attempting to dress, to sit down in a chair, or to get into bed, will suggest at first a severe confusion or dementia, though subsequent examination may show that he is in fact fully orientated and his intellectual capacity in general is unimpaired

Perhaps of greater interest are the transient and episodic upsets seen in certain epileptic variants These represent focal fits originating in the posterior parietal cortex They range from some limited manifestation such as the sudden feeling that one limb is moving or has assumed some unusual posture, when it can be seen to be stationary or in quite a different position, to the hallucinatory experience of a complete image of the self (autoscopy) projected into external space, such as the famous instance of Goethe meeting his double coming towards him on the road to Weimar

Similar disorders of body image may be found in migraine, either as an aura to an attack or as a migrainous equivalent Lippman[1] drew attention to such phenomena and pointed out that the fantasies of altered bodily size and shape in *Alice in Wonderland* were very similar to the descriptions of their symptoms given by some migrainous patients Recently Todd[2] has described 6 further cases He emphasises that these symptoms may sometimes occur apart from the more usual manifestations of migraine, and will often cause much anxiety and fears of insanity Both he and Lippman point out that Lewis Carroll (C L Dodgson) himself suffered from migraine, and suggest, in Todd's words, "that Alice trod the paths and byways of a wonderland well known to her creator" If that is so, English literature is the richer for Mr Dodgson's migraine

PSYCHOSOMATIC RESEARCH

RESEARCH on mind-body relationships calls for the ability to recognise clearly a change in mental state and an acceptable method of measuring its consequences in the body Physiology may provide tested methods of measuring bodily changes, but psychology has not yet evolved ways of measuring changes of mental state These difficulties have not deterred investigators, and during the past half century a considerable volume of literature on the subject of psychosomatic relationship has accumulated This literature is candidly described by the editors of the newly published *Journal of Psychosomatic Research*[3] "Nowhere in medicine is there such a contrast between the wide span of theories and their narrow factual basis" This new international journal has been started with the admirable object of encouraging workers on psychosomatic relationships to apply scientific methods to their studies The editorial policy is to publish only the results of investigations in which hypotheses have been clearly formulated and tested by well planned experiments, and the scope of the articles published will be wide enough to include controlled clinical investigations, animal, human, or experimental work, and relevant studies from such related fields as psychology, sociology, and anthropology

The first two papers of the new journal, by Dr Brian Ackner, provide a good example of how psychosomatic relationships can be scientifically investigated The problem was to study the effect of anxiety on peripheral vasomotor activity Ackner considers possible methods of investigating vasomotor activity, and he concludes that the measurement of finger pulse volume is the most suitable technique Its advantages are that the apparatus is simple and unobtrusive, so that the subject's emotions are not aroused by the procedure, and it is sufficiently sensitive to define clearly the changes observed Patients were chosen from psychiatric inpatients who complained of constant anxiety and appeared anxious and tense throughout the day Observations made on this group were compared with observations on a second group of inpatients who were objectively and subjectively free from anxiety, and also with observations made on a group of normal persons Previous work had shown that the peripheral vasomotor tone is affected by many factors, and it was necessary for this investigation to show that the effects observed were solely attributable to anxiety The patients were observed in as basal a state as possible and then all emotional effects were removed by inducing sleep with quinalbarbitone ('Seconal') If anxiety produces abnormal digital vasoconstriction, sleep in

ected Unfortunately no marrow biopsy was done Whole od was transfused between April 6 and 27 1955, but hout any real benefit Cystoscopy and intravenous pyelo phy were done at the time The pyelogram, which suggested ease of the left kidney, proved a stumbling block and nporarily delayed a correct diagnosis On April 30 and y 7, 1955, the correct diagnosis was suggested by peri eral blood counts, which showed a low white cell count in first and large numbers of blast cells in the second On y 1, 1955, the patient developed a left sided hemiplegia, læna, and ecchymoses on the left cheek and buttocks She d on May 9, 1955

Necropsy showed a cerebral hæmorrhage and acute myeloid kæmia The thyroid contained many calcified and fibrous enomata, with a little pale pink colloidal thyroid tissue erspersed between the adenomata There were no leukæmic iltrations or deposits The bone marrow of the sternum, rtebræ, and upper two-thirds of the femora was soft and ldish green and had undergone myeloid leukæmic trans mation There was also leukæmic infiltration of the spleen, er, and renal pelves The last-named showed signs of ent hæmorrhage There was a minor degree of leukæmic iltration in the right occipital lobe of the brain, the mucosa the œsophagus and several lymph glands which were, wever all small and inconspicuous the largest measuring ×1 0 cm Dr J V Dacie reviewed the relevant necropsy aterial, and confirmed the diagnosis of acute monocytoid yelogenous leukæmia

Discussion

It would be improper at this stage to draw any conclu- on about the part, if any, played by irradiation in the duction of leukæmia in this particular case We merely eport the development of acute myeloid leukæmia in a oman treated for thyrotoxicosis with radioactive iodine ghteen months earlier Before treatment with radio odine she had been given carbimazole for ten weeks

Ionising irradiation has already been shown to be at ast a *contributory* cause of leukæmia in man under ertain conditions (March 1950, Folley et al 1952, Lange t al 1954, Court Brown and Abbatt 1955 Moloney and Kastenbaum 1955) Leukæmia has so far been reported n 5 other cases after radio-iodine (Delarue et al 1953, eidlin et al 1954, 1955, Blom et al 1955), but they were ases of carcinoma, in which much larger doses of radio- odine are given, and in 2 of them external radiation was lso given The cases of Pochin et al (1956) and urselves are the only ones so far reported in which eukæmia has followed the administration of the smaller loses of radio iodine necessary in the treatment of hyrotoxicosis It is important to emphasise that both ases were of acute leukæmia, a disease difficult to diag- nose without hæmatological facilities, and that therefore unrecognised cases could easily occur

It is not infrequently assumed that radiation in small doses—e g , in diagnostic X-ray examinations and in the radio-iodine treatment of thyrotoxicosis—does not damage enough tissue to initiate leukæmia But the ætiology of leukæmia remains unknown, and it is known that ionising radiation can play a part in its induction in certain conditions It is important to assess the risks of radio-iodine treatment as soon as possible by direct observation in man rather than by extrapolation from animals Such data can only be obtained from a large-scale survey of patients treated with radio-iodine and comparison with a suitable control group We suggest that the evidence is now good enough to warrant such a survey

Summary

A case is reported of a patient in whom acute leukæmia developed eighteen months after treatment with radio- active iodine for thyrotoxicosis

We wish to thank Dr J V Dacie Dr I Doniach and Dr S Robinson *for their help*

INTERMITTENT POSITIVE-PRESSURE RESPIRATION

AN UNUSUAL COMPLICATION IN AN INFANT

W E LAWES
L R C P E F F A R C S, D A, D T M & H
ANÆSTHETIC SPECIALIST

J R HARRIES
M D Lond. M R C P, D C H, D T M & H
MEDICAL SPECIALIST

KING GEORGE VI HOSPITAL, NAIROBI KENYA

POSITIVE PRESSURE respiration introduced by Lassen (1953), has become an established form of treatment for certain conditions (*Lancet* 1955) but reports of its use (Macrae et al 1953, Smith et al 1954, Harries and Lawes 1955) refer only to adults or children, and we have found no description of its use in infants

We describe here *our* experience with an infant suffering from acute bulbospinal poliomyelitis who was treated by this technique

Case-report

A well nourished African infant aged 10 months, was admitted to the poliomyelitis unit in Nairobi on Sept 30, *1955 from an up country hospital* The patient who had been ill for six days, had been brought to the hospital originally because of inability to suck Notes taken on admission to the first hospital read as follows ' semi comatose, temp 101°F alæ nasæ working, respirations 60, diaphragmatic movement good some paradoxical movement of the upper chest, palate does not appear to move and the patient is unable to swallow

Investigations and Treatment

The cerebrospinal fluid contained 135 mg protein per 100 ml and 35 cells per 100 ml A stomach tube was inserted for feeding purposes Oximeter readings (mean of *six*) showed the arterial oxygen tension to be 94 6%, but this figure improved to 97% when oxygen was given From time to time suction of the nose and pharynx was needed to remove secretions The child s condition appeared to be maintained at a reasonable level without any respiratory aid We were unable to estimate the vital capacity or the pCO_2 Seven hours after admission the intercostal paralysis increased rapidly and paradoxical movement became more pronounced

The various combinations of filament size, weave, synthetic material, and its treatment which are now obtainable from the manufacturers are enormous, and it is obvious that much further research is needed to define the best type of tube. It seems likely, however, that improved fabrics will very soon be in use, and they may largely replace arterial homografts.

ALDOSTERONE

RECENT work has illustrated that our understanding of the syndromes associated with excessive secretion of aldosterone is by no means complete.[1] The chief problem at present lies in reconciling the clinicians' identification of a syndrome which they believe to be due to increased aldosterone secretion with the biochemists' failure to detect increased amounts of aldosterone in the urine or blood. This difficulty has arisen on at least two occasions. The first patient was described in our columns by Dr Chalmers and his colleagues,[2] and had the characteristic features believed to be due to excessive aldosterone formation: intermittent muscular pains, cramps, weakness, and paralysis; hypertension; polyuria, nocturia, and albuminuria; hypokalæmia and alkalosis. The second case (an even more difficult diagnostic problem) was described by Dr M. D. Milne to the section of endocrinology at the Royal Society of Medicine on April 25. An otherwise healthy woman complained of occipital headaches, was found to have hypertension, and was referred to hospital. A routine electrocardiogram revealed the changes of hypokalæmia which was confirmed by flame photometry. There was no muscle weakness or tetany, and no adrenal tumour was seen on X-ray examination, even after air insufflation and tomography. Nevertheless both patients were found at laparotomy to have adrenocortical tumours, removal of which righted the biochemical abnormalities, and in neither was there preoperative evidence of increased urinary excretion of aldosterone. One possible explanation for this paradox is that the tumours were secreting some hormone other than aldosterone but with similar physiological effects; or it may be that the present methods for estimating aldosterone are unsatisfactory. A similar difficulty has also arisen in the investigation of toxæmia of pregnancy. In patients with this condition increased amounts of a sodium-retaining substance are excreted in the urine, as judged by bio-assay procedures.[3,4] With justifiable speculation it has been suggested that this substance is aldosterone, but Dr J. D. Martin and Dr I. H. Mills reported, in a communication to the Society for Endocrinology on May 4, that they had failed to find any difference in the amounts of aldosterone excreted by normal pregnant women and patients with toxæmia. Venning and Dyrenfurth[5] have briefly reported similar negative results.

At the Royal Society of Medicine Dr J. F. Tait reviewed very clearly the methods, biological and physicochemical, for estimating aldosterone. Since the ratio of hydrocortisone to aldosterone secreted is about 60 to 1, the amount of aldosterone in the blood (0·08 µg. per 100 ml.) and in the urine is extremely small, and this is largely responsible for the difficulties of estimation. Nevertheless there remains a disturbing and unexplained difference in the quantity of aldosterone found in normal urine by British[6] and Swiss[7] workers. Little is known of the form or forms in which aldosterone is excreted. According to Dr Tait, the yield is increased threefold by hydrolysis at pH 1; Venning and Dyrenfurth[5] used both acid and glucuronidase hydrolysis. Failure to hydrolyse all the conjugates, as well as lack of knowledge about the metabolites of aldosterone, may therefore be in part responsible for the low urinary excretion in some cases of alleged hyperaldosteronism. Dr Tait suggested that the nephropathy caused by hypokalæmia[8,9] might result in diminished excretion of aldosterone in patients with hyperaldosteronism, but he emphasised that in the patient studied by Chalmers et al. the blood level was not raised. Dr I. Bush put forward a point in favour of regarding some cases of "hyperaldostéronism" as due, not to aldosterone, but to some unidentified hormone. He contrasted the large amounts of aldosterone excreted in secondary aldosteronism (cirrhosis, nephrosis, and congestive cardiac failure) and the much smaller or normal amounts in some cases of alleged primary aldosteronism. Until these questions have been resolved, diagnosis and management of primary aldosteronism must rest, as ably shown by Dr Milne, on the clinical findings and metabolic disturbances, without depending on the detection of increased amounts of aldosterone in the urine or blood.

ELECTROLYTES IN TUBERCULOSIS

ABNORMALITIES of the serum electrolytes have been described in tuberculous patients, both with and without antibacterial treatment. Hypokalæmia has been demonstrated during treatment with *p*-aminosalicylic acid[10-12] and with viomycin.[13,14] Low serum-sodium or serum-chloride may be found in untreated patients who are very ill with miliary, meningeal, or pulmonary tuberculosis, but no important changes in serum-potassium have been found.[15] Crofton and his colleagues[16] have lately reported 4 instances of low serum-potassium in patients with miliary tuberculosis having antibacterial treatment that included neither isoniazid nor viomycin. The serum-chlorides were also low in 3 of their patients. In all 4 there were severe symptoms of hypokalæmia with lethargy and profound muscular weakness, but in only 1 did the symptoms appear during the acute phase of the illness; 2 patients had symptoms during convalescence, and in another they were preceded by an attack of biliary colic and vomiting. Simple replacement therapy with sodium, potassium, and chloride produced considerable improvement, and in at least 2 patients it may have been life-saving. Crofton et al. conclude that the electrolyte disturbances were due to the cumulative effects, in severely ill patients, of decreased potassium intake (the result of poor appetite), and to increased potassium loss caused by mild diarrhœa and occasional vomiting, with, possibly, poor renal conservation.[17] It was not possible to examine the electrolyte balance in such gravely ill patients; but Crofton et al.'s paper is published at an incomplete stage of their investigations in order to draw attention to the condition. Electrolyte upsets in tuberculosis may be more common than published reports suggest; and it is possible that some who "just fade away" may in fact die from this remediable cause.

a valve whereby air could be forced into the lungs but was prevented from escaping In the present case it was difficult to imagine a valve mechanism The possibility of erosion into the œsophagus, with the end of the endotracheal tube lying partly in the trachea and partly in the œsophagus, which might cause dilatation of the stomach or possibly some kind of valve mechanism, was considered but withdrawal of the tube had no effect Suction and squeezing produced no result this time, cyanosis became extreme and the apex beat could no longer be heard As the infant was rapidly dying a needle was inserted into the abdomen, without effect

When the apex-beat had not been heard for one and a half minutes an incision was made through the abdominal wall and as the peritoneum was incised air rushed out At first it was thought that the air had escaped from a puncture of the distended stomach, but a hurried search showed that this was not so The child's condition had improved by this time, cyanosis was less and the pulse could be felt at the wrist A catheter was quickly sewn into the stomach to prevent any further dilatation of the stomach, and the abdomen was sutured As the abdominal wall was being sewn the abdominal distension returned Cutting the peritoneal sutures relieved the distension by allowing air to escape It was now certain that the positive pressure respiration was forcing air into the abdominal cavity The infant was by this time moribund and died shortly afterwards

NECROPSY

Necropsy showed

1 Ulceration of the trachea on the posterior wall but not through to the œsophagus A large clot of blood was resting on the endotracheal tube above the taracheostome There was no sign of surgical emphysema round the trachea or œsophagus

2 Surgical emphysema of the right lung running into the mediastinum, which contained a large number of bullæ

3 Small bullæ running down the œsophagus from the mediastinum into the abdomen

4 Bullæ on the greater and lesser curvature of the stomach, some of these were about $^3/_4$ in in diameter

Discussion

Acute dilatation of the stomach is a fairly common complication of acute poliomyelitis, and fatal cases have been recorded (Hussein 1952, Perreau 1952) In this case the dilatation was severe enough to interfere seriously with positive pressure respiration and could be relieved only by squeezing the abdomen The radiograph taken after the third attack showed that there was no surgical emphysema at that time Presumably the operator during the last attack had allowed the inspiratory pressure to rise too high in an effort to overcome the resistance of the distended stomach, and as a result the alveoli had ruptured into the perivascular spaces and from there air had travelled back into the mediastinum (Macklin 1939, Macklin and Macklin 1944)

Mediastinal emphysema has been described as arising from air trapped in the peritoneal cavity during operations (Baggot 1952) and also as a complication of pneumoperitoneum (Towbin 1951), but we were unable to find any reference to pneumoperitoneum arising from mediastinal emphysema This was the first time we had employed finger respiration, and it is unfortunate that we did not incorporate a safety device in the system as we had done with the Radcliffe respirator

The danger of tracheal ulceration from an endotracheal tube in a small infant was recognised, but we were unable to obtain a suitable silver cannula with a chimney such as is used in Sweden (C G Engstrom, personal communication) These cannulæ have a more acute bend than rubber tubes and have a wider internal diameter

The blood-clot found in the trachea at necropsy was large enough to have completely occluded the trachea, and thus emphasises the need for laryngeal and tracheal toilet before removing the intratracheal cannula

Summary

A case of bulbospinal poliomyelitis in a 10 month old infant is described

The difficulties of intermittent positive pressure respiration in an infant are outlined Acute dilatation of the stomach may threaten life The positive-pressure system should include a safety device to prevent excessive pressures

In the present case death was due to surgical emphysema

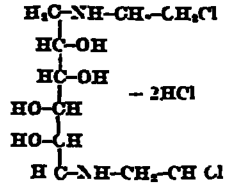
Preliminary Communication

CLINICAL TRIAL OF A NEW NITROGEN-MUSTARD COMPOUND

A NEW type of compound has been prepared by Dr L Vargha by linking a nitrogen mustard with mannitol to form 1, 6-bis (β chlorethylamino-1, 6 desoxy-D-mannitol) dichloride (B C M) (see formula), which strongly inhibits the growth of metastasising tumours and proliferating lymphocytes



$$\begin{array}{l} H_2C\text{–}NH\text{–}CH_2\text{–}CH_2Cl \\ HC\text{–}OH \\ HC\text{–}OH \\ HO\text{–}CH \\ HO\text{–}CH \\ H_2C\text{–}NH\text{–}CH_2\text{–}CH_2Cl \end{array} \cdot 2HCl$$

The recommended dosage of B C M is 1 0–1 5 mg per kg of body-weight administered intravenously on alternate days to a total of 900–1000 mg B C M is easily soluble in physiological saline solution and well tolerated when injected either intrapleurally or intra abdominally in man Intramuscular and subcutaneous injections should not be given The effect of giving B C M by mouth is being investigated No untoward side effect has been observed with a total dose of 1200 mg If that dose is exceeded, there is a risk of agranulocytosis (which, however, can be cured by treatment with corticotrophin)

We report here the results obtained clinically in various malignant disorders

CLINICAL TRIAL

Chronic Lymphoid Leukæmia

The best results were obtained in this disease in 6 of 7 patients an initial leucocytosis of 100,000 per c mm was reduced to normal In 1 of them severe skin lesions which had resisted all previous treatment regressed, and in 1 other a cervical lymph-gland as large as an apple disappeared All 7 patients put on weight, and several months after the end of the treatment they needed no further medication

Chronic Myeloid Leukæmia

In 3 cases the leucocytosis was reduced and the patients put on weight In 1 case the spleen became smaller In 3 other cases improvement was only temporary

Acute Leukæmia

In 2 cases pyrexia and the number of hæmorrhages were reduced, but in 2 other cases no effect was observed

TABLE II—SOURCES OF PATIENTS REFERRED IN 1954

unclassified group were patients referred to find out if full resolution had taken place after a pneumonic infection and to exclude the possibility of an underlying carcinoma.

Bronchial carcinoma is becoming of increasing importance in chest work. In 72.6% of the 84 cases of bronchial carcinoma shown in table III the diagnosis was established pathologically by bronchoscopic biopsy, by finding of malignant cells in sputum or pleural fluid, by thoracotomy, or at necropsy. In most of the remainder pathological proof has not yet been obtained, because the patient's age and/or general condition makes surgery unadvisable. A thoracic surgeon attends on one afternoon a week to do bronchoscopy, operable cases of bronchial carcinoma being admitted direct to a thoracic surgical unit, and a follow-up examination of both doubtful cases and patients who have undergone resection is done in the chest clinic at a joint session held with the medical staff and the thoracic surgeon. Suitable inoperable cases of bronchial carcinoma are referred to the regional radiotherapy centre and then continue under clinic observation.

Respiratory tuberculosis is classified under three headings:

(1) *Notified cases* are those in which there is no doubt that an active lesion requiring treatment is present. The sputum in most cases is proved to contain tubercle bacilli either by direct smear or culture.

(2) *Observation cases* comprise patients who have radiographic evidence of tuberculosis but in whom there is doubt regarding the activity of the lesion, the sputum being negative and serial radiographs and observation being necessary for a final assessment of activity of the lesion.

(3) *Inactive cases* consist mainly of patients whose radiographs reveal calcified or hard shadows but who have no symptoms or physical signs.

TABLE III—DIAGNOSES IN THE 1602 NEW CASES

Diagnosis	Male	Female	Total	Average age (yr.)
Respiratory system				
Tuberculosis (notified)	98	54	152 (9.4%)	37
Tuberculosis (observation)	104	109	213 (13.2%)	38
Inactive tuberculosis	62	98	160 (9.9%)	54
Bronchitis and emphysema	110	42	152 (9.4%)	56
Bronchial carcinoma	76	8	84 (5.2%)	58
Spontaneous pneumothorax	11	0	11 (0.6%)	33

Miscellaneous	5	1	6 (0.3%)	30
Other systems				
Tuberculosis (notified)	10	6	16 (0.9%)	21
Miscellaneous	4	4	8 (0.4%)	50

Tuberculosis Contacts

All domiciliary contacts of both notified and observation cases attend the clinic both for chest radiography and a tuberculin test. In 1954 22 contacts were found to have a definite lesion when seen for the first time in the chest clinic, and 11 of them were notified as having active tuberculosis. There is an average of 4 domiciliary contacts for each case of tuberculosis. Continued follow-up of contacts is restricted to those in whom it is thought that there is some risk of subsequent development of tuberculosis, such as those in susceptible age groups and those in persistent contact with a patient with positive sputum. Where it is considered desirable, B.C.G. vaccination of young contacts is done. Despite selection of contacts requiring continued supervision there were 5314 attendances in 1954.

Treatment of Tuberculosis

We now have various methods of treating pulmonary tuberculosis and are only beginning to realise the great value of prolonged treatment with streptomycin, *p*-aminosalicylic acid, and isoniazid. As a result there has been a big drop in the death rate from tuberculosis, whereas the incidence of tuberculosis has decreased only a little. As a result all chest clinics have a bigger register of cases.

The Ministry of Health lays down that all patients must be followed up for at least five years from the time the tuberculosis becomes quiescent before they can be classed as recovered. Patients are usually seen at increasing intervals during this period and, unfortunately, relapses are discovered each year.

Before 1948 tuberculosis was one of the few diseases for which treatment was free and patients usually agreed to go wherever a bed was available. Since the introduction of the National Health Service Act there has been an increasing reluctance, and even refusal, of patients to go far away from home, with the ensuing paucity of visitors. The acute shortage of beds which existed up to two years ago led to the institution by chest clinics of domiciliary treatment, early admission to hospital being reserved for homeless persons living in lodgings and for those with poor housing conditions. Today the general standard of housing is much improved, and many patients prefer to have most of their treatment at home, being admitted to hospital only for minor collapse measures or to a special chest hospital for major surgical operations. Such a programme means that the patient remains mainly under the care of his own family doctor, and his progress is usually reviewed monthly at the chest clinic, transport being provided by the ambulance service, and streptomycin being injected by the district nurse.

Advice in the prevention of the spread of tuberculosis is given by the health visitors, who are employed by the local health authority (in this area the Middlesex County Council) and work from the chest clinic, so that they are in close contact with the medical staff. Some patients are admitted to the general hospital beds for various periods for assessment or for such procedures as induction of an artificial pneumothorax or pneumoperitoneum and the division of pleural adhesions. These beds are also essential for the admission of emergencies in patients treated at home and for patients with conditions which it is undesirable to admit to a general medical ward when there is a possibility that tuberculosis may be the cause.

Reviews of Books

Ophthalmology

A Textbook for Diploma Students P D TREVOR ROPER F.R C S, curator, department of pathology, Institute of Ophthalmology, London London Lloyd Luke 1955 Pp 656 75*s*

THE author set out to write a textbook of ophthalmology for those taking the diploma in this subject, and he has based its contents on the current teaching and practice of the Moorfields Eye Hospital and its related Institute of Ophthalmology Although the preface suggests an apology for the use of ' didactic and dogmatic diction,' this is quite proper, and indeed desirable and necessary, for a book of this kind containing the essentials in a short and well-written text enlivened by good illustrations

Three sections deal with the basic sciences on which ophthalmology rests Another devoted to optics has at its end a well illustrated chapter on methods of inspection The remaining two parts of the book are concerned with diseases of the outer and inner eye, and there is a final chapter on the visual pathways

Maintaining the high traditions of a distinguished literary family Mr Trevor-Roper's easy style and attractive composition are a pleasure to read Clearly this is a textbook which many postgraduates will want to have

Surgery in World War II

Vascular Surgery Editors DANIEL C ELKIN, M D MICHAEL E DEBAKEY M D Washington D C Office of the Surgeon General Department of the Army 1955 Pp 465

THIS volume was prepared by the Historical Unit of the United States Army Medical Service, under the editorship of Dr Elkin and Dr DeBakey It gives a reasonably complete account of the arterial complications of war-time injuries in Servicemen and the results to be expected with surgical and conservative treatment The U S Army wisely grouped into selected hospitals of the ' zone of interior " all their vascular cases under the supervision of experienced specialists As a result of this policy our knowledge of arterial injuries has been greatly extended, and the whole volume stands as a tribute to the meticulous documentation investigation, and surgery of the hospitals concerned The chapters are written by well-known authorities, such as Simeone, DeBakey, Freeman, and Shumacker, who were in active control of this work during the war, and the standard of presentation is exceptionally high

As a worthy successor to Makins's classical work, this book clearly reflects the progress that has been made during the two wars in the understanding and treatment of vascular injuries Without doubt it will become a standard work

Transplantation of Tissues

LYNDON A PEER M D, clinical and research director, Rehabilitation Center for Plastic Surgery St Barnabas Hospital, Newark, New Jersey Baltimore Williams & Wilkins London Bailliere Tindall & Cox 1955 Vol. I Pp 421 £5 2*s* 6*d*

THE author of this beautifully and expensively produced volume is a well-known plastic surgeon and authority on surgical research who has made important contributions to the fundamental technique of tissue transplantation He has a wide knowledge of the basic physiological problems of plastic surgery and this is the foundation of the work His own contribution to knowledge in the form of cartilage implants is seen in its many applications to facial and aural reconstruction He covers fully the other fields of tissue transplantation, with a very large bibliography A general pattern of animal and human operations has been followed and autogenous, homologous, and heterologous grafts are compared and contrasted Indeed, some may say that the book attempts too much

The chapter on cell preservation is almost an apologia, for there is no information of value in the remarks on tissue culture, and the section on freeze-drying technique is little more than a summary of some of its history The presentation of the problem of vital storage at very low temperatures is made without reference to the work of Parkes and Smith at Mill Hill though future applications of this work in Dr Peer's own department are mentioned

It is a little difficult to imagine for whom this book has been written. for the original experimental material which might have made a more opportune appearance as a formal monograph, is mingled with more speculative and practical matters concerning the clinical aspects of plastic and reconstructive surgery in general The book will, however, have a real value as a reference source

Cardiovascular Innervation

G A G MITCHELL CH M D SC professor of anatomy and director of anatomical laboratories, University of Manchester Edinburgh E & S Livingstone 1956 Pp 356 55*s*

UNTIL the publication of this book there was no monograph in English on the innervation of the human cardiovascular system Lazorthes's treatise is in French and descriptions by White Smithwick, and Simeone, and Kuntz are in works which are chiefly concerned with function and not structure Professor Mitchell's new book fills this gap He has selected relevant details from the extensive literature often confirming and augmenting them by his own investigations He has reviewed and occasionally modified existing hypotheses blending all into a composite picture, though first place has been given to Man Many topics are explained and illuminated by morphological embryological physiological, pathological, and clinical considerations But the provision of complete details in fields other than anatomy has not been the chief aim and an extensive bibliography is provided for those who want further information on specific problems

In a foreword, Sir Geoffrey Jefferson, F.R S, rightly observes that " this is a book on applied anatomy but a book with a difference—the difference being that the author is a vastly more erudite and better informed anatomist than the great majority of those who teach applied anatomy It is not only a comprehensive but a well-balanced account "

The Normal Child and Some of his Abnormalities

C W VALENTINE, D.PHIL. Harmondsworth Penguin Books 1956 Pp 291 3*s* 6*d*

WRITING for the intelligent reader untutored in psychology Dr Valentine describes the mental and intellectual capacity of children from babyhood to adolescence and their behaviour and development He sets out ' to stress individual differences as normal and to show that many things thought by some (psychiatrists especially) to be signs of serious abnormality are not so ' This he does relying partly on published observations, partly on observation of his own five children and of others known to him Family doctors and parents of sizeable families will find more confirmation of their own experience than surprises , but anyone with fears for the normality of a child under their care should read this book before concluding that the worst is in store

Anxiety and Stress

An Interdisciplinary Study of a Life Situation HAROLD BASOWITZ HAROLD PERSKY, SHELDON J KORCHIN and ROY R GRINKER London and New York McGraw-Hill 1955 Pp 320 60*s*

THIS informative study was carried out by four members (a psychiatrist, a biochemist, and two psychologists) of the staff of the Institute for Psychosomatic and Psychiatric Research and Training of the Michael Reese Hospital, Chicago They studied a group of paratroop candidates during the three strenuous weeks of their practical training Systematic observations were made to determine how visual perception, memory, intellectual control, and other psychological activities were affected by the stress of airborne training and at the same time hippuric-acid excretion plasma-glycine plasma-amino-acid blood-reduced-glutathione, and eosinophil levels were estimated

Special Articles

COMPOSITION OF FLOUR

THE panel appointed by the Government in May, 1955, to investigate the composition and nutritive value of flour[1] has now reported[2] Its main conclusion is as follows

> "Taking into account all the circumstances, and bearing in mind particularly the needs of the vulnerable groups in the population, the Panel concludes that the available evidence does not reveal any ascertainable difference between National flour as defined in the Flour Order, 1953, and flours of extraction rate less than National flour, to which vitamin B_1, nicotinic acid, and iron have been restored in the amounts specified in the Flour Order, 1953, which would significantly affect the health of the population in any foreseeable circumstances They believe, however, that differences between low extraction flour enriched as specified and low extraction flour not so enriched are significant"

Last week the Minister of Agriculture, Fisheries, and Food announced that the Government had accepted this conclusion (see p 810)

National flour is defined under the Flour Order, 1953, as follows containing the maximum quantity of wheat germ which, having regard to the type of milling, can be included in such flour, (2) not including any coarse or added bran, and (3) consisting of wheat flour, being either of 80% extraction or of substantially the same nature and containing substantially the same quantities and proportions of constituents as flour of 80% extraction

THE CONFLICTING VIEWS

The panel summarises two conflicting views

On the one hand, the Government's medical and scientific advisers and the Medical Research Council claim that, since bread contributes, on a national average, a third of the total calories of the diet, National flour of 80% extraction makes it virtually certain that the diet as a whole will provide enough protein, vitamin B_1, nicotinic acid, and iron, and that, in addition, such flour provides useful quantities of other essential nutrients for which the criteria of adequacy are less well defined If the extraction rate were lowered to 70%, there would be a loss of protein, vitamin B_1, nicotinic acid, and iron, and, even if these two vitamins and iron were restored by enrichment, a reduced intake of other vitamins might in some circumstances be reflected in nutritional deficiencies

The representatives of the milling industry, on the other hand, claim that between National flour of 80% extraction and whiter flour of lower extraction, enriched with vitamin B_1, nicotinic acid, and iron to the levels obtaining in National flour, any differences in composition are insignificant when related to the diet as a whole

TRIAL IN GERMAN SCHOOL CHILDREN

The panel refers to the trial in undernourished German children of flours with different degrees of enrichment and different extraction rates (from 70 to 100%)[3] The principals in this trial told the panel that their experience would lead them to believe that the difference between unenriched low extraction flour and higher extraction flours is less than was thought at the time of the Conference on the Post War Loaf[4] and is probably small enough to be ignored when the diet is otherwise well balanced

THE PANEL'S CONCLUSIONS

The panel concludes that a true 80% extraction flour will contain, as compared with flour of lower extraction-rate (taking 70% extraction as a reference-point) (*a*) more of certain essential nutrients, such as protein, vitamin B_1, nicotinic acid, and iron, (*b*) more of the other essential nutrients such as pyridoxine, pantothenic acid, biotin, and folic acid, and (*c*) a little more riboflavine It is, however, a simple process to add vitamin B_1, nicotinic acid, and iron to lower extraction flours so that the contents of these nutrients amount to or exceed those in 80% extraction flour, without impairment of technical quality The panel has an open mind about the significance of the other differences "The history of nutrition reveals many instances where the refinement or over purification of food has led to ill health and there is no reason to believe that this chapter of knowledge is closed"

The panel was particularly impressed by the fact that 10% of British children may pass their childhood in circumstances in which they depend on flour to supply certain essential nutrients in sufficient amounts "The panel is of the opinion that nutrition in such individuals would fall below the level necessary for good health if there were a return to the pre war practice of making bread from flour of extraction rates of 70 to 72 per cent to which vitamin B_1, nicotinic acid, and iron had not been restored" There is some evidence that the quality of the protein of 70% extraction flour is less than that of 80% extraction flour, but the panel believes that when 70% extraction flour is blended with the remainder of the diet its use is most unlikely to give rise to symptoms of protein malnutrition Lowering the extraction rate from 80 to 70% is very unlikely to lead to any nutritional disturbance from lack of pyridoxine, pantothenic acid, biotin, or folic acid

Compared with a 70% extraction enriched flour a true 80% extraction flour may give a more widely spread insurance against possible, but as yet unproved, deficiency in the rest of the diet, but 70%-extraction enriched flour gives a more certain cover against possible deficiency of the three "token" nutrients (vitamin B_1, nicotinic acid and iron) whose lack is associated with well recognised deficiency states

The panel was impressed by the evidence of demand, by millers, bakers, and public, for white flour and white bread There is a risk, the industry claim, that if people can obtain only bread made from 80% extraction flour they may eat less bread and more of other manufactured foods which may not be so nourishing

The panel precedes its main conclusion by expressing its belief that experience has demonstrated that "a policy of enrichment provides a realistic means of ensuring that the greatest nutritional benefit is derived from flour" But flours of higher extraction rate, containing no less nutrients than the enriched low extraction flours, should be also available The National Food Survey, it adds, should continue to be of great help in the periodic review of policy concerning bread

HEALTH IN SCOTLAND IN 1955

EXPECTANT mothers, the newborn, and young children are singled out, statistically and traditionally, as in need of special protection against health hazards The report[1] of the Department of Health for Scotland suggests that to these vulnerable groups we should now add "men towards the latter half of middle age"

Last year the maternal and infant death rates each touched a new low record There were *43 maternal deaths* (compared with 70 in 1954) or 1 maternal death per 2200 births The infant death rate in 1955 fell to 10 7 per 1000 births, compared with 15 6 per 1000 five years ago The school medical officers found that infections were declining among their charges, while *growth* was more rapid and maturity attained earlier The major hazard to these children is now transport accidents

of the periphery of the bone.[19] While changes in the sacro-iliac joints are usually the most readily demonstrable, characteristic changes may be displayed by special projections in the costovertebral and lumbar apophyseal joints.[20] Fusion of the sacro-iliac joints as the result of ageing processes is probably commoner than is generally realised,[21] and bridging by osteophytes in multiple disc degeneration is an obvious diagnostic trap. According to Mowbray et al.,[9] the disc spaces may be narrowed in ankylosing spondylitis unless they are buttressed by early ligamentous ossification. In adolescent kyphosis there is characteristically a compensatory exaggeration of the lumbar lordosis—in contrast to the flattened lumbar curve of ankylosing spondylitis.[4] Fluorosis can cause a crippling condition of the spine and pelvis which may mimic ankylosing spondylitis clinically,[22] producing fusion of vertebræ and calcification of the spinal ligaments at their attachments. Sclerosis of the bones in fluorosis is a characteristic distinguishing feature, and Steinberg et al.[23] found no excess of fluorine in the bones and soft tissues in a patient with ankylosing spondylitis. The intake of fluoride needed to produce these changes enormously exceeds the amount which could be derived from fluorinated drinking-water.

The diagnosis of ankylosing spondylitis is more difficult in women than in men, and sometimes involves the interpretation of the radiographic phenomenon of osteitis condensans ilii. This lesion, a triangular area of sclerosis in each ilium, with its base on the sacro-iliac joint, seems to be commoner in women, and to be associated with low back pains developing during pregnancy or the puerperium. Changes in the sacro-iliac joint itself are absent or inconspicuous. Thompson[24] reviewed 20 patients originally regarded as having osteitis condensans ilii, and concluded that 7 were actually suffering from ankylosing spondylitis. Like Tyson et al.,[25] he believed that ankylosing spondylitis occurs in a restricted or abortive form in women. In a very large number of patients treated with X rays Sharp and Easson[26] found that the response was distinctly better in typical cases of ankylosing spondylitis than in those with unusual features. The hands or feet were involved in 52.5% of "atypical" cases and in only 12.5% of the others. Tendinitis and tendon lesions were rare in the latter but were not uncommon in the atypical group. It seemed unlikely that the atypical group was composed largely of cases of rheumatoid arthritis, for the differential agglutination test was positive in only 12%.

From this atypical category Thomas[27] attempted to separate a group which were, he believed, examples of chronic arthritis due to repeated attacks of rheumatic fever. Recurrent severe attacks of pain in the back in these patients were readily relieved by salicylate. Some had changes in the peripheral joints of the type described by Jaccoud[28] and Bywaters[29] in rheumatic fever. Radiographically they showed very small erosions in the sacro-iliac joints, surrounded by spotty sclerosis, and in the spine irregularity and fusion of the interfacetal joints, narrowing of disc spaces, sometimes ossification within the discs and an increase in the height of vertebral bodies. Fusion of the sacro-iliac joints is fairly frequent in the arthritis associated with psoriasis and was commonly found by Birkin et al.[30] (together with the familiar high incidence of cervical spondylitis) in juvenile rheumatoid arthritis. Finally, ankylosing spondylitis, or something very like it, seems fairly common in non-specific urethritis.[31]

Treatment

Suggestive evidence that radiotherapy is not free from serious risk was published last year by Court Brown and Abbatt.[32] In a series of 9364 patients treated between 1940 and 1954, the observed deaths from leukæmia were at least five times, and possibly as much as ten times, the expected number (calculated from the male age-specific death-rate for leukæmia in England and Wales for 1953). The risk seemed to be greater if more than one course of treatment had been given. Court Brown and Abbatt quoted van Swaay's data on 7 patients who had died from leukæmia after X-ray treatment for spondylitis. There was some evidence that patients with ankylosing spondylitis may be unusually susceptible to leukæmia. On the basis of these findings, Court Brown and Abbatt concluded that it would be wrong to withhold X-ray treatment from those suffering from ankylosing spondylitis, but that treatment should not be given unless the diagnosis is unshakeable, and should be repeated only if absolutely necessary. Phenylbutazone has proved in many hands to be more effective in relieving pain in ankylosing spondylitis than in most other rheumatic diseases (except gout). This drug, too, has its hazards and in one series[33] produced toxic effects in 34% of cases, compelling its withdrawal in 6%. It should certainly be tried only if aspirin has been proved inadequate. Continuous treatment with corticotrophin was provisionally favoured by West and Newns[34] for those severely affected patients who received little benefit from radiotherapy. Adrenal stimulation should not be greater or maintained for longer than absolutely necessary. Immobilisation is rightly condemned nowadays as harmful, and prevention of crippling deformity is best achieved by prescribing a firm bed with a low pillow and the avoidance of prolonged stooping at work, or of heavy lifting with the spine flexed. Breathing exercises and extension exercises for the back are important measures. In severe cases with fixed kyphosis, spinal osteotomy[35 36] is occasionally indicated, and for badly affected hips the Batchelor operation has been helpful.[37]

The picture which emerges from Blumberg and Ragan's[1] study of the natural history of the disease warrants a more optimistic attitude than that induced by the exceptional case of severe deformity. In their words, "while the physical deformity and the confirmatory X-ray changes appear to proceed relentlessly with the passage of time, the manifestations of acute disease, i.e., the pain and E.S.R., are at their highest during the early phases and then decrease. The period of acute symptoms and signs is short, relative to the entire length of the disease. Systemic illness is not as common in this disease as in peripheral rheumatoid arthritis." In general, patients had an excellent occupational history. "The insulting agent, whatever it may be, does not appear to have a sustained effect, whereas the ankylosis of joints, presumably a reaction to the original insult, may take years to achieve completion. The patient is not placed in constant jeopardy of repeated devastating attacks which may lead to further acute injury to the joints (and viscera) as is commonly seen in peripheral rheumatoid arthritis." Very few patients were reduced to a bed and chair existence, and of 16 patients whose disease had been present for twenty-one to twenty-five years 13 were still in full employment.

THE LANCET

LONDON SATURDAY MAY 26, 1956

A New Clinical Entity?

In 1917 von Economo[1] reported a small outbreak of an illness in which the main features were fever, stupor, and ophthalmoplegia 2 of his 13 patients died and at necropsy there was evidence of inflammation of the brain substance During the next two years a great many similar outbreaks were recorded and by 1921 the disease had reached epidemic proportions in almost every country in Europe[2] In spite of perplexing variations in the clinical picture from case to case locality to locality and even from season to season[2] it soon became clear that for practical purposes a new clinical entity had appeared[3] In 1924 5039 cases of encephalitis lethargica were notified in England and Wales alone,[4] but by the beginning of the next decade confirmed cases of this dangerous disease had become sporadic and by 1939 they were extremely rare[5] By the end of the late war, the centre of interest had shifted to poliomyelitis as by far the most prevalent and disabling infection of the nervous system The work of Ritchie Russell and others[6] focused attention on the importance of diagnosis in the pre-paralytic stage, and from other sources[7 8] there was evidence of a change in the epidemiology of poliomyelitis

Against this background of intense interest in poliomyelitis and its problems came reports of outbreaks[9–11] and isolated cases[12 13] which for one reason or another led to difficulties in diagnosis Broadly, these can be divided into those in which the cerebrospinal fluid (C S F) is abnormal and those in which it is normal Of the abnormal group (group I) only in the series described by Laurent[10] was no convincing causative organism isolated The conditions described by Kelleher[12] and Jennings[13] proved to be aberrant poliomyelitis and there was presumptive evidence of the same disease in the outbreak reported by Barrett[9] from Cambridgeshire in 1949 The Coxsackie group of viruses has also been implicated in this group[11 14] in such cases pleocytosis is the rule and signs of parenchymal damage to the nervous system are very uncommon Much more perplexing outbreaks are those in which no changes are found in the C S F (group II) Since we discussed these illnesses in 1954 under the non-committal title, Not Poliomyelitis[15] another epidemic with similar features has been reported from Durban[16 17] and two further outbreaks are described in this issue by Dr Sumner and by Dr Ramsay and Dr O Sullivan Only a brief description[18] has so far been published of the alarming outbreak at the Royal Free Hospital last year but there are arguments for including it in this group In none of these cases has it been possible to incriminate the poliomyelitis or Coxsackie virus, nor indeed has any other known infective agent been isolated

There seem good reasons in our present state of ignorance for placing in a third and intermediate group the epidemic which took place in Akureyri, Iceland, in the winter of 1948–49,[19] and about which Dr Sigurdsson and Dr Gudmundsson write on p 766 In all 8 cases examined the C S F was abnormal on the other hand the protracted course and mental symptoms described by Dr Sigurdsson are prominent symptoms in group II The outbreak in the nurses training school in the University of Pennsylvania in 1945[20] is also difficult to classify since it happened before the isolation of the Coxsackie viruses there was pleocytosis in 2 out of 5 cases The unusual epidemic reported by Wallis from Cumberland in 1955[21] has many features of group II —notably vertigo, diplopia, myalgia, cervical lymphadenopathy, and protracted convalescence with mental symptoms Unfortunately there is no information about the C S F The recorded atypical outbreaks can thus be grouped as follows

		Virus	*C S F*
Group I	Laurent[10] (1947)	Unknown	Usually abnormal
	Kelleher et al.[12] (1949)	Poliomyelitis	
	Curnen et al[11] (1949)	Coxsackie	
	Jennings et al[13] (1949)	Poliomyelitis	
	Barrett et al[9] (1952)	Poliomyelitis	
	Galpine and Macrae[14] (1953) and others	Coxsackie	
Group II	Adelaide[22] (1949)	Unknown	Normal in nearly all cases
	New York State[23] (1950)	Unknown	
	Middlesex Hospital[24] (1952)	Uncertain	
	Coventry[25] (1953)	Unknown	
	Berlin (1954) (Sumner)	Unknown	
	Durban[17] (1955)	Unknown	
	Royal Free Hospital[18] (1955)	Unknown	
	Hampstead (1955) (Ramsay and O Sullivan)	Unknown	
Group III	Pennsylvania[20] (1945)	Unknown	Abnormal 2 5
	Akureyri, Iceland[19] (1948)	Unknown	Abnormal 8 8
	Cumberland[21] (1955)	Unknown	Unknown

Of the 8 outbreaks in group II, all except that at the Royal Free were initially confused with polio-

Letters to the Editor

HOME CONFINEMENT

SIR,—May I, as a general practitioner, make a few comments in reply to Professor Russell's article in your issue of May 12?

I am surprised that he is so eager to increase the numbers of women admitted to hospital for confinement. To suggest that "normal midwifery only exists in retrospect" was no doubt purposely provocative, but this is unfortunately believed by many of our patients, and perhaps one of the important functions of the general practitioner is to explain to his expectant mothers that the processes of pregnancy and parturition are physiological rather than pathological.

Many primiparæ approach the time of delivery with a certain amount of understandable dread. This is not likely to be diminished by attending hospital clinics where they may not be seen by the same doctor or midwife on consecutive attendances. In the labour wards they are supervised by whoever happens to be on duty. It does not seem that the continuity which Professor Russell seeks is to be found here.

Professor Russell makes a passing reference to cross-infection in hospital. I think pædiatricians would agree that this is a very real problem in the care of the newborn in hospital: not only are these infections common but they are often caused by organisms resistant to all except the newer antibiotics. In my experience neonatal infections are rare in babies delivered at home.

The establishing of breast feeding is surely easier where the general practitioner is able to cooperate with the midwife. He will normally have a more detailed knowledge of the mother than has the hospital obstetrician. He should be more likely to anticipate the mother's worries and difficulties.

Professor Russell's suggestion that a general practitioner should not be allowed to attend delivery in the home seems to me particularly unattractive: if a general practitioner has not been trained to diagnose those emergencies and difficulties which require hospital treatment or specialist advice, then his training has been inadequate. Surely a doctor who is not aware of his limitations should not be practising at all.

I hope that these comments will help to justify the right of the general practitioners to continue practising obstetrics. Many patients will still need to be confined in hospitals or maternity homes on social grounds. Perhaps there is a strong case for increasing the number of beds available to general practitioners in maternity homes.

Bolton, Lancs. MICHAEL FASNACHT

SIR,—In your leading article of May 12 you reiterate the cliché that "if every [general] practitioner does only his own numerical share of obstetrics he will not have enough continuing experience to remain efficient." This is quite wrong. You should have written "if he deals only with that part of his share which is now left to him."

The ratio of general practitioners to births per annum is about 1 to 40 (and of practising midwives only 1 to 47). Four-fifths of pregnancies and labours are normal enough to be supervised by general practitioners. Any general practitioner who gives complete ante-, intra-, and post-natal care to 30 or more cases per annum will not only remain adequate in the type of obstetrics required in general practice, but will probably become more so.

Unfortunately many normal cases are delivered in specialist hospitals for a variety of peculiar reasons, and others are in the hands of self-reliant midwives. For the remainder the general practitioner is encouraged and paid to give only essential support to a midwives' service, and no more. Lack of experience and, when it exists, lack of interest are largely due to these limitations on the volume of general practitioner obstetrics; for, even under present conditions, only one general practitioner in six wishes to give up maternity work. Without these limitations, which are artificial, there would be no need for that artificial limitation of maternity practice—the obstetric list.

The service at present provided for "normal" cases is a midwives' service, supported by the general practitioner or the house-surgeon according to the place of delivery. It is a good service, but there is evidence that even better results can be obtained if there is closer cooperation between doctors and midwives, particularly at deliveries. To produce such a service, it is necessary to permit and encourage the practitioner to attend all his maternity cases, and to pay him to provide a complete service instead of a limited one.

If this were done your nostalgic picture of the family doctor and trusted friend bringing the son and heir into the world (or shall we say attending the delivery at which the midwife does so?) would not be anything like as unrealistic as you suggest. It is a vista greatly to be recommended to the committee now set up to inquire into the maternity services, for it has many advantages over the more impersonal arrangements. A maternity service based on the family doctor and local midwife working in close cooperation, with the specialist service at their disposal, is as likely as any to be that which best serves the interests of mother and child.

Gloucester. IVOR COOKSON

SIR,—I have read with interest Professor Russell's article. This is the latest in a long series by consultants in obstetrics which have sought to debase the general practitioner obstetrician.

In this district it is the usual practice for all primigravidæ to be delivered in hospital. In subsequent pregnancies some, if they have had a normal delivery the first time and prove to be progressing normally, are confined at home; others, if their medical and/or obstetric history dictates it, are confined in hospital. Such conditions as twin pregnancies and breech presentations are always referred to hospital. In this district also the local health authority allow the general practitioner obstetrician to do the antenatal work at the welfare centre, with the help of the health visitors, &c.

I myself do this and follow the antenatal session with an infant welfare clinic in which I see the babies routinely from about 14 days old to roughly 18 months. This, I find, adds to the interest of general practice enormously. At the first visit the expectant mother is examined fully, blood is taken for Wassermann reaction and ABO and Rh grouping, and arrangements are made for routine radiography of the chest. Relaxation and mothercraft classes are also held at the clinic, which each mother is encouraged to attend. So at first with monthly visits and later with weekly visits her health and the progress of her pregnancy are watched and her education is completed.

I agree that theoretically, from the purely obstetric viewpoint, it is desirable for every confinement to take place in hospital. There are, however, some objections, the gravest to my mind being the antibiotic-resistant bacterial population of every hospital, and the risk of infection—particularly infection of the newborn. I cannot see that the standard of antenatal care given by general practitioner obstetricians who are interested and keen is as low and as dangerous as is made out. I hope that it is not, as numbers of women will have to be confined at home for some years to come unless more money can be allotted for new building.

I agree that Professor Russell's students need not go into the home to learn the simple operative techniques that are all the general practitioner obstetrician should attempt, but having learnt them in the hospital let them harboured penicillin-resistant strains—twice as high an incidence as in 1954 In his article last week Dr Fairbrother concluded that one removable cause of the trouble was the habit of using penicillin indiscriminately for all forms of trivial infection His plea that "a stricter control of penicillin therapy is urgently required" will doubtless find many supporters, but it is probable that the only available control will be such self-control as doctors can bring themselves to exercise in their own use of penicillin and other antibiotics The arguments for such self-control have often enough been repeated in these columns the dangers of sensitisation of patients, of severe toxic reactions, of diminishing usefulness of antibiotics in serious infections, and of such grave superinfections with resistant organisms as, for example, an often fatal form of enterocolitis All these things have been said so often by so many writers that it is now becoming difficult to repeat these exhortations without wearying those who heed them

In this situation, however, it may still be worth commenting on some of the evidence about the adaptability and versatility of the staphylococcus Fairbrother, for example, now shows—contrary to what was at one time believed—that penicillin-sensitive and penicillin-resistant staphylococci isolated from the same lesion may quite often be of the same phage-type In 25 cases in which such pairs of staphylococci were isolated, the resistant and sensitive organisms were of the same phage-type in 11 Barber and Burston[29] regarded the penicillin-resistant organisms as the variant or mutant strains, but Fairbrother thinks it possible that *Staphylococcus aureus* formerly led a wild existence in which it produced penicillinase and that this function was later largely, but not entirely, lost by prolonged adaptation to the human nares This interpretation means that the penicillin-sensitive staphylococci are mutants derived from penicillinase-producing penicillin-resistant strains In support of this idea, Fairbrother found it easy to derive penicillin-sensitive variants from penicillin-resistant penicillinase-producing strains by growth at 44°C, but he was unable to accomplish the opposite change Fairbrother's speculation gains some added interest from Dr Phyllis Rountree's observations, which we also published last week, on the staphylococci harboured by the Wabaga, a primitive self-contained race inhabiting a remote part of New Guinea and thus isolated from outside contacts and so from antibiotics and those who might carry antibiotic-resistant organisms 23 of 120 Wabaga were nasal carriers of strains of *Staph aureus*, none of which was antibiotic-resistant Among 110 strains of non-pathogenic (coagulase-negative) staphylococci found in nasal swabs from the Wabaga, 87 conformed to Shaw et al's[30] definition of *Staph saprophyticus*, and of these, 6 were penicillinase-producers 2 of these strains were resistant also to chloramphenicol, 1 strain was resistant to streptomycin, chlortetracycline, and chloramphenicol, and 1 penicillin-sensitive strain was resistant to chlortetracycline Much experimental evidence is quoted by Eagle and Saz[31] in their authoritative review on antibiotics, all of it pointing, like Rountree's findings, to the conclusion that the antibiotic-resistant variants, now so common, are in fact preformed mutants which grow out selectively in the presence of the antibiotic The only difference between this and Fairbrother's view is that Fairbrother would regard such resistant forms as the begetters of the race which are being restored to their original position by our malpractices

True, we may derive some comfort from the fact that many bacteria are less able than the staphylococcus to produce resistant forms—a point stressed by Finland[32] in three recent papers on the emergence of antibiotic-resistant bacteria Thus, with penicillin we have no resistant forms of group-A hæmolytic streptococci, pneumococci, gonococci, or spirochætes It is probably true that tubercle bacilli and staphylococci create the greatest clinical problems so far posed by antibiotic-resistant forms of pathogens, but we must not forget the gradually increasing clinical importance of such naturally antibiotic-resistant genera as, for example, proteus pseudomonas, and aerobacter and of the non-hæmolytic streptococci and enterococci Against any comfort we may get from concluding that only a few genera of micro organisms are involved, we must set the evidence which suggests that staphylococci are responsible for an ever rising incidence of clinical infections of some severity in man In their article this week Dr Disney and his colleagues quote findings which, if they are of general application mean that any child of less than 2 years with clinical signs of pneumonia or of fluid has more than three chances to one of being infected with *Staph aureus* Among the staphylococci isolated by lung puncture from these infants, 20 strains were tested for sensitivity to antibiotics and 14 were found to be resistant to penicillin Moreover, on p 771 Dr Duncan Evans and Dr Myrddin Evans show that staphylococcal infection of the lower respiratory tract in adults may produce a severe and often fatal illness during influenza epidemics In these cases the cause of death appeared to be the rapid and abundant production of staphylococcus toxin in the lungs

Brodie et al[33] recently emphasised once again their view that in any particular hospital the important staphylococci may belong to only a few types carried in the noses of the staff In exactly such circumstances Rountree et al[34] report success in controlling neonatal staphylococcal infection by treating the noses of the staff with an ointment containing bacitracin and neomycin—a procedure following the method introduced by Gould and Allan,[35] whose choice of oxytetracycline, however, was in some ways less likely to be satisfactory for such a purpose Lepper[36] suggests nine methods of dealing with the problems we have discussed (1) combinations of drugs, (2) introduction of new drugs, (3) diminishing the use of a drug against which many resistant infections have appeared, (4) reduction in the use of all antibiotics to a minimum, (5) use of drugs of limited antibacterial spectrum and their use in their minimal suffering from repeated attacks of epilepsy and we were unaware of the history of head injury, the patient being admitted for investigation as a case of possible cerebral tumour The 5th patient was a young adult who again was decerebrate on admission

As you point out, the development of unilateral fixation and dilatation of a pupil, although a valuable lateralising sign, is invariably a late sign and one of danger, indicating that speedy measures will have to be taken to relieve pressure on the brain stem

It is clearly impossible for all these cases to be saved, but I feel that a recovery-rate of 75% should be our aim When it is remembered that a tentorial pressure cone may develop and result in decerebrate rigidity within a matter of twenty to thirty minutes or less, then it is manifestly unwise to subject a patient suspected of suffering from this condition to an ambulance journey of perhaps fifty to sixty miles In its common form, this condition is one of the few surgical emergencies in which minutes really do count, and in my opinion these patients should be operated upon at the nearest hospital

NORMAN WHALLEY

PLASMINOGEN IN AGAMMAGLOBULINÆMIA

SIR,—It is well established that a proteolytic enzyme is present in normal blood in the form of an inert precursor, plasminogen, which is attached to the globulin fraction (Cohn fraction III 3) An inhibitor, plasmin, is present in excess in the albumin, and in the α_1 and α_2 globulin fractions

We have found repeatedly that plasminogen was associated with the γ globulin fraction, which was obtained by treating 0 4 ml of serum with 9 6 ml of saline ammonium sulphate The yield of γ globulin was estimated photo electrically using Weichselbaum's biuret reagent (90 g Rochelle salt in about 400 ml of $N/5$ NaOH, 10 g $CuSo_4 5H_2O$, 10 g pot iodide, made up to 2 litres with $N/5$ NaOH) The purity of this fraction was confirmed by paper electrophoresis

Recently in a woman with "agammaglobulinæmia" there was nearly complete absence of γ globulin and comparatively normal levels of albumin and α_1 and α_2 globulin fractions Despite this, normal proteolytic activity of serum was observed on activation by streptokinase

MEDICINES FOR HOSPITAL OUTPATIENTS

SIR,—After being seen at an outpatient clinic of one of London's children's hospitals a mother collected from the dispensary a bottle of over one hundred capsules for her child The child was unable to swallow these and the mother asked me whether she should destroy them in case they were dangerous There was no indication on the bottle of the nature of the capsules but after much inquiry I was informed that they were an antibiotic preparation—cost, nearly twenty pounds Luckily in this case I was able to prescribe a more suitable form of the antibiotic for the child and to return the capsules to the hospital With a perhaps less intelligent mother, the twenty pounds' worth of medicine might well have gone down the drain

This experience is not an isolated one, by any means Is it really necessary for hospitals to supply medicines to their outpatients? Would it not cause less strain on short staffed hospital dispensaries, be more helpful to patients and their family doctors, and be much less wasteful if hospitals confined their prescribing to in-patients? For outpatients a short note to the family doctor suggesting the treatment required is surely the procedure of choice

St Mary Cray, Kent

E TUCKMAN

MENTAL DEFECT AND HYPSARRHYTHMIA

SIR,—I am distressed to find sectarian jargon appearing in one of your annotations Under the above title in your issue of April 28 I read that "the children had salaam attacks," and that "Ounsted has shown that the phenotypic expression of the convulsive genotype is rapidly overcome by maturation" It is often difficult to understand the many papers which have been written jointly by three or four workers in different fields, and your more simple readers look to the annotations for clear explanation and comment

St Mary's Hospital
London, W 2

R G HOWELL

G M C ELECTION

SIR,—I was very glad to read the letter from Dr Whiteside and Dr Dillon (May 12) I completely agree with them about the evils of an electoral procedure which allows pressure groups to keep independent candidates out of the G M.C

The B M A sent to the profession at large a card urging it to poll for seven names No mention was made of the two other candidates, and, if this card did not create the impression that no more than seven existed, it certainly helped to exclude the two youngest Not content with influencing its own members, the B M A made it a self appointed obligation to canvass tho that stay out of the association

I voted for Dr Whiteside and Dr Dillon to the exclusion of the B M.A nominees I hope that at the next election the B M A will show more tact, and perhaps, then, young unsponsored candidates will be more successful

Thames Ditton, Surrey

L R CHRISTIN

BACTERIAL RODENTICIDES

SIR,—Dr Taylor's article (May 5) provides useful reading on laboratory findings, and controversial opinions on rodent control economic practice

The article details objectionable methods never or no longer used in this country It is well established in practice that, under proper safeguards, the use of bacterial cultures of the right kind is a safe and important contribution to the war against rodents, themselves of much greater danger to mankind

Statutory Rules and Orders made it obligatory from Oct 1, 1945, that—inter alia—no liquid virus should enter into retail trade, and no *Salmonella enteritidis* var *jena* should be manufactured No case is recorded by Dr Taylor of human illness attributed to anti rodent virus up to the time when those Orders were revoked in 1950

In 1951 the Working Party on Toxic Chemicals was asked to investigate rodenticides—including virus The working party reported in 1953 The Ministers of Agriculture, Food, and Health and the Secretary of State for Scotland considered the recommendations in this report, and after consulting the trading interests affected announced—via the Minister of Agriculture—that the firms had agreed to collaborate with the Departments, "it being borne in mind that these preparation which are not on sale to the general public have been in use on a considerable scale for many years" It was recorded that of the four specific recommendations made two were already in current practice, and the remaining two were accepted with minor modifications The future collaboration envisaged was as to the adequacy of the agreed safeguards in practice Since these arrangements were made no untoward incident has been brought to notice

Table III of Dr Taylor's article refers to jena having been isolated in 1948–49 No human illness was involved The firm concerned supplied voluntarily to

PREVENTION OF INDUSTRIAL ACCIDENTS

Of some 7 million workers employed in factories in this country over 450 are killed and about 160 000 injured each year. In addition over 250 workers are killed and more than 20,000 injured in workplaces other than factories subject to the Factories Acts. Though these figures are lower than the toll of accidents on the roads and in the home they have far-reaching social and economic consequences—and all are preventable. In its recently published report,[1] the industrial safety subcommittee of the National Joint Advisory Council reviews the whole subject of industrial accidents and makes important recommendations for future action. The National Joint Advisory Council comprises representatives of the British Employers' Confederation, the Trades Union Congress, and the boards of nationalised industries under the chairmanship of the Minister of Labour and National Service, and it advises the Government on matters in which employers and workers have a common interest. The recommendations should therefore carry great weight with both sides of industry.

Accident prevention is not new, because the Factory Department and voluntary organisations have paid close attention to it for many years. The subcommittee has, in fact, nothing very original to say on the subject, but it describes how organised action in this field developed out of common law relating to masters and servants and out of statutory protective legislation. In the first place, it was concentrated more on the provision and maintenance of safe physical working conditions than on the human side of accident prevention. This is true even today, and the subcommittee, by implication, does not seem to think that the medical profession (though naturally it has to deal with the results of accidents) has a large part to play in accident prevention. The report points out that most accidents arise from ordinary everyday causes such as handling goods, using hand-tools, or falls; in nearly all cases there is some failure of the human element. No reference is made to the fact that doctors could give much greater assistance than they are at present called upon to do. Admittedly, the subcommittee says that team-work and coöperation are essential "first of all in the workplaces between employers and workers, and between industry and the Factory Department, research organisations, voluntary organisations, teaching bodies and many others such as architects and doctors." But it seems that the emphasis is a little out of perspective.

The subcommittee's recommendations in general constitute a plea for more of everything except accidents. Both employers and workers should take more interest in the subject, and accident prevention should not be subordinate to production; there should be more safety officers and works safety committees and more training of workers, especially of young workers. Firms should insist upon getting premises and plant with "built-in" safety. Full use should be made of available knowledge and experience in the works and as necessary information and advice should be sought from outside the works—in particular from Her Majesty's inspectors of factories, the Factory Department publications, the Industrial Health and Welfare Centre, industrial organisations, specialist firms and consultants, and voluntary organisations.

Hitherto industrial research organisations have usually concentrated on production problems, and it is hoped that safety research will now be accepted as a function of these organisations. Voluntary organisations such as the Royal Society for the Prevention of Accidents, should continue to develop opportunities for the exchange of information and experience, and arrangements for the dissemination of information and publicity material. The subcommittee thinks that, though the official Factory Department publications are excellent within limited fields, they are inadequate both in kind and range. As well as more technical papers for specialists there is a great need for relatively brief and practical publications for employers and workers. The report recommends the production of films about safety in industry (though the present Government policy precludes direct expenditure of public funds on the production of such films), and arrangements are encouraged whereby such films could be made widely available through the Central Film Library.

In the matter of training, the education departments, local education authorities, colleges, and schools should examine the possibility of further developing safety-training as a part of general education. For this purpose there should be liaison between the schools and colleges, industry, H.M. inspectors of schools, and H.M. inspectors of factories. Another point in the report is that the Factory Department should intensify its work on accident prevention with which it has been concerned for more than a hundred years, and the subcommittee comments on the future rôle of the department in the light of its recommendations. The contribution of the inspectorate will be no less important in the future than it has been in the past, both in its enforcement functions and in the advisory work which often arises out of enforcement. As industry shows itself capable of achieving higher standards, it is hoped that there will be a further shift of emphasis in the work of the inspectorate from enforcement of the law to the giving of advice. It is important, however, that the standards of inspection should be high, and that the number of qualified inspectors should be maintained and increased as necessary.

Finally, the report urges that all concerned should examine afresh every possible means of helping to promote higher standards of safety in industry, both directly and indirectly, and take the opportunities they have to increase their contribution. A standing national committee, including representatives of Government and industry, should be established to keep under constant review all aspects of industrial safety, including research.

CHONDROMALACIA OF THE PATELLA

Fissuring and flaking of the articular cartilage of the patella (chondromalacia) is one of the commonest forms of degenerative change seen in joints. Owre,[1] in a series of post-mortem examinations, found these changes mostly in persons over the age of 20, but they are relatively rarely associated with symptoms. Since it seems that nearly all adult knees show changes of this type, it is hard to assess the natural course of the condition. The cases studied by Karlson[2] suggest that chondromalacia, even when associated with symptoms referable to the knee, does not necessarily progress. Of 71 patients treated conservatively, only 20% were substantially disabled by the knee. Arthritis deformans seemed to be a relatively uncommon development, and in this series it was never severe.

Chondromalacia of the patella begins as a nodular swelling of the articular cartilage, which becomes opaque. The lesion is localised and is associated with a decrease in the condroitin-sulphate content. Fissuring and flaking may follow later, and may involve the whole articular surface. The flaking often produces scales which may result in cartilaginous loose bodies. Marginal osteophytes can later develop and the femoral condyles occasionally show "mirror" lesions.

observation was being made Perhaps the plump male or postpartum female who goes on a diet of apples is in as much danger as those of us who over eat modern foodstuffs (innocently being starved of some essential food factor) I have been assured (without reference) that the cholesterol in the bile of the starved is increased

The rise in the incidence of hospital cholelithiasis in Scandinavia is staggering, the disease appears to be more fulminating than in this country In Gothenburg in the main hospital nearly 1000 gall bladders were removed in 1954 (pre-war about 200) Clinical talk has it that the increase in the disease started in Finland after the war, the intensity is now maintained all over Scandinavia While I have had (without any facts) suspicions concerning manufactured foods such as margarine for some time, I was intrigued to see the powerful research machines in these centres being turned towards this very subject Sjovall is studying the effects that diet has on the metabolism by the liver of cholesterol and bile salts [4] (Scandinavia, by the way, lives on margarine, the butter being exported)

It may well turn out that starvation (including the essential fatty acids) and overfeeding in the fully grown (including the wrong fatty acids) are equally dangerous to our welfare We must aim for unadulterated freshness in food and guard against excess of any kind This may be the unthinkable answer, so we must spend fortunes and many lives to prove it, and when the pudding is done, who will want to eat it ? Perhaps the most that will happen will be a sudden increase in pamphlets and wealth of pharmaceutical firms turning out essential food factors (alas for medicine and the patients—they have jumped the gun already !)

This letter may be considered threadbare and no windbreak to the gusts which rush and flutter around Dr Sinclair's edifice, yet threads there are, and strong

Queen Elizabeth Hospital,
Birmingham

A J H Rains

Sir,—I was glad to see in your issue of May 12 the widening response to your leader of April 28

Since my previous letter appeared (May 12), Prof H Malmros has kindly sent me samples of the artificial milk used in his experiments, in which a considerable amount of corn oil is incorporated I am glad to find that it has a very pleasant taste, and I hope that food manufacturers in this country will soon market similar products, including cheese and ice cream

OBSERVER ERROR

Sir,—In the report of their investigation of observer error in M M R film readings Dr Eley and Dr Paxon (April 21) are not justified in their conclusion that "the number of truly active cases missed by A was around 5% and by B 7%" They derive this conclusion from their observation that Dr A missed 8 5% and Dr B 13 5% of all cases, and the presumption that only half of these would be active, for they have halved the numerator of the equation

$$\frac{\text{Total cases missed}}{\text{Total cases}}$$

but left the denominator alone In the experiment of Yerushalmy et al, to which they refer, the proportion of sputum positive cases missed was greater (42 5%) than the proportion of inactive cases missed (30%) The same was true of "active" cases in the investigation by Clayson et al [5] and may well be true of the cases in their own experiment—or it may not The case against the importance of observer error cannot be made by faulty arithmetical manipulation A follow up of the cases could provide a correct assessment of the proportion of active and sputum-positive cases missed

Dr Eley and Dr Paxon have only shown the amount of error between two readers (who may happen to have had very similar methods and abilities) Yerushalmy et al took great care to ensure that their "positive cases" were all the undoubted positives agreed upon by ten readers in consultation Among the 10,000 films read by Drs A and B there may have been some positives which they both missed and which are not included in their "error" In this sort of work the size of the sample of readers is as important as that of the sample of films that is read

A SHORT WAY WITH *TÆNIA SAGINATA*

Sir,—Dichlorophen (2 2′-dihydroxy-5 5′ dichloro diphenyl methane) a white, almost tasteless solid, is an established veterinary remedy for *tæniasis* of dogs and cats Its action differs from that of other tænifuges in that it has a direct lethal effect upon the worms which after being killed, are subjected to the digestive process of the intestinal secretion, so that the parasite is evacuated in a hardly recognisable state

The earliest reference to its veterinary use is in a careful paper by Craige and Kleckner,[1] in which they reported success rates, in dogs infected with *Tænia pisiformis* and *Dipylidium caninum*, of 75% with doses of 50–100 mg per kg body-weight and of 90% with a dose of 200 mg per kg They investigated the mode of action of the drug by examining dogs killed at various intervals after dosage, and found that after thirty to forty minutes the tapeworms were detached from the intestinal wall and were passing along the ileum After two hours the worms were in the colon and were markedly degenerate The minimum lethal dose for dogs lies between 2 and 3 g per kg body weight

The results obtained in the first six cases of *T saginata* infection I treated by this remedy were as follows

Case no	*Dose (g)*	*Result at 16 weeks*
1	6	Cured
2	3	Recurrence *after 10 weeks*
3	4 5	Cured
4	6	Recurrence *after 11 weeks*
5	2	Cured
6	6	Cured

Each of these patients was admitted to hospital for convenience of observation No preliminary starvation or subsequent purgation was used The dose—0 5 g per 16 lb (7 25 kg) body weight—was given, all at once, at about 10 A M After two or three hours most of the patients experienced mild colicky pains and passed two or three loose motions These were carefully examined, but nothing of the worms could be found except varying numbers of more or less disintegrated mature segments It was not possible, therefore, at the time of treatment to know whether the scolex had been destroyed and the patient cured *T saginata* takes not more than twelve weeks to grow from a scolex to the point where the host begins to pass segments The patients were therefore followed up for at least sixteen weeks

The cure rate in this small series of cases is reasonably satisfactory The explanation of the two failures may be that, because of the drug's laxative action its contact with the scolex was too fleeting for its lethal effect to operate It may well be that by giving repeated smaller doses over a period of twenty four to thirty six hours a more certain action will result, and I have lately tried the effect of giving a total dose of 6 g in three equal amounts at intervals of twelve hours anxious persons should be associated with an increase in finger pulse-volume, whereas untroubled patients, or normal people, would show no such change. The findings showed that the three groups studied differed significantly both in the size of the pulse volume during the resting state and in the increase in pulse-volume during sleep. The increase in finger pulse-volume in the anxious patients clearly distinguished them from the other two groups. The findings therefore indicate that anxiety is associated with an increased level of peripheral vasomotor activity.

[1] Craige A H Kleckner A L N *Amer Vet* 1946 27 [illegible]

Other somatic manifestations of anxiety—tachycardia, increased blood-pressure and respiration-rate, and changes of skin electrical resistance—were found to be unreliable as measurable indications of anxiety. Further work may indicate whether the degree of anxiety is related to the amount of pulse-volume change as sleep ensues; if it does so, then we would have an objective method of assessing the degree of anxiety at different times in any one patient. It is very unlikely that the method could be used to assess by how much the degree of anxiety in one patient differs from that in another.

After this good beginning, standards are not quite so high in the other papers in this new journal. If the "narrow factual basis" of psychosomatic research is to be widened, somatic manifestations and psychological disorders must both be clearly defined and described in specific terms. "Mixed neurosis," "social inadequacy," "neurodermatosis" or "-itis," and "social isolation" are not precise terms. Control groups must be impartially investigated, and the tests used must be such that, when they are repeated in the same subject, the difference is less than the differences between normal and abnormal subjects. It seems likely that secure progress cannot be made in psychosomatic medicine until a better knowledge of psychosomatic physiology is available. Psychosomatic research needs the work of investigators comparable to Harvey, Claude Bernard, Starling, Dale, and Lewis, and one of the new journal's aims will be to encourage this fundamental work.

CAROTID THROMBOSIS IN THE YOUNG

SEEMINGLY spontaneous carotid thrombosis in the young adult has been known as a rarity for fifty years or more. Carotid angiography has more recently uncovered a surprising number of such cases. The finding poses afresh the problem of ætiology, because the usual degenerative factors held to contribute to thrombosis do not apply at this age. A few thromboses can be clearly classified as traumatic. Blows to the neck in boxing, for instance, may occasionally be responsible; the nature of the local injury and the timing of symptoms leave little doubt about the causal link. In one or two cases the circumstances suggest that some upset in water or electrolyte balance is the cause. Thrombo-angiitis obliterans and giant-celled arteritis are uncommon in any form, and even rarer as a cause of carotid obstruction. Ill-defined constitutional factors, such as operate in families more than usually susceptible to thrombosis in general, presumably play a part; but in most cases the cause and even the occasion remain obscure.

In 1942 Cairns[1] first suggested the possibility that damage to the carotid at some distance from the site of blockage may start a local thrombosis which then extends spontaneously. He described a closed head injury with thrombosis at the carotid syphon. Sedzimir[2] reconsidered the matter recently and gave details of 6 cases in which blunt injury to the head seemed to precipitate carotid thrombosis, starting intracranially and spreading down into the neck. In the 4 cases where the diagnosis was confirmed by necropsy or angiography the injury was frontal. In 1 there was an associated atheroma which probably contributed to the thrombosis. In all 4 some time elapsed between injury and the onset of signs of thrombosis, and in 2 this amounted to several days. Some of these cases undoubtedly confirm the view that head injury may initiate a spreading carotid thrombosis. Such a cause must therefore be carefully considered in apparently spontaneous carotid thrombosis in the young. The relationship may the more easily be missed since not all the recorded cases had severe head injuries and there was a variable interval between the trauma and its effects. At a time when thrombotic disease seems to be on the increase, any information about the factors causing or favouring its production has a general interest and application.

SYNTHETIC ARTERIES

THE replacement of diseased or blocked arteries by human homografts is undoubtedly one of the major surgical triumphs of recent years. Large series of successful transplants in the distal aorta have been recorded by DeBakey and Cooley[1] and Bahnson[2]; more recently Holmes Sellors[3] has described 3 patients with coarctation of the aorta associated with a proximal aneurysm in which both lesions were resected en bloc and continuity restored by an arterial graft. We recently suggested[4] that the by-pass operation for femoral-artery blocks holds great promise. Admittedly, despite many experiments with the preservation and sterilisation of homologous vessels, there remain many objections to their use. It is not always easy to obtain a sufficient number and range of young homologous aortas or smaller arteries, and their sterility may be difficult to ensure. Freeze-dried or quick-frozen arteries are non-viable and depend essentially on their elastic fibres to prevent the dilatation and disruption which is occasionally reported.[5,6] Even so, the results of homologous arterial transplantation are good, although sufficient complications and difficulties have been described to make safer replacements desirable.

Blakemore et al. suggested[7] that fabric tubes might be used as an alternative, and they later demonstrated that 'Vinyon N' cloth, folded and stitched longitudinally in a tube, was in fact capable of acting as a scaffolding for the ingrowth of fibroblasts. Many technical questions immediately presented themselves, some of which are gradually being answered. Impermeable tubes are less satisfactory than a mesh weave which allows fibroblastic ingrowth for the surrounding host tissue to form a new intima; but if the mesh is too big, with holes of larger than 50–100 μ, then there may be uncontrollable and fatal oozing through the wall.[8] Hufnagel[9] used 'Orlon' and 'Dacron' cloth because their water-repellent qualities limit this type of bleeding; others have used 'Ivalon' sponge and polyvinyl sheets. A serious objection to all fabric grafts is the possibility of kinking with subsequent clotting if the insert material is too long or if the graft crosses a flexion area such as the groin, axilla, or popliteal space. To overcome this "wrinkle" thrombosis Edwards and Tapp[10] have experimented with crimped or "concertinaed" nylon tubes, which are treated with silicone to discourage bleeding through the open mesh. This design has the advantage of allowing the graft to take up slack and pass round sharp angles without wrinkling. The rough corrugated inner surface to the crimped tubes causes much turbulence in the blood-flow; but although one might suspect that this would encourage postoperative clotting, this was not in fact so, even with tubes of a diameter of 0.5 cm.

A little solemn, I thought—but then, of course, you were addressing a man old enough to be your father

The plain truth is that I must not make a virtue of necessity I retire at sixty-five, and that's that I am not a special case Thanks all the same for your friendly advice which I shall try humbly to follow It has been such fun since you wrote

Yours truly,
J M MACKINTOSH

Parliament

Capital Punishment

ON the committee stage of the Death Penalty (Abolition) Bill in the House of Commons on May 16 an amendment, moved by Sir Hugh Lucas-Tooth, a former under-secretary to the Home Office, providing for the retention of the death penalty where murder is committed by prisoners already serving a life sentence, was carried by 4 votes—198 to 194 The amendment was supported by Major GWILYM LLOYD-GEORGE, the Home Secretary, who said that Parliament had already thought it right to protect prison staffs against attack falling short of murder by preserving corporal punishment for offences of this kind It seemed right that prison staffs should have analogous protection against attacks that killed Mr SYDNEY SILVERMAN, the promoter of the Bill, described the amendment as the greatest nonsense in the world What he asked, had this to do with an offence which everybody conceded had never happened in living memory in any country? The committee were being asked to retain the death penalty, with all its solemnity of the gallows, the black cap, and the rest, for a purely imaginary danger

QUESTION TIME

Nutritive Value of Flour

Replying to a question, Mr D H AMORY, Minister of Agriculture, Fisheries and Food, said that the main conclusion of the Panel on the Composition and Nutritive Value of Flour was that the available evidence did not reveal any ascertainable difference between National flour as defined in the Flour Order, 1953, and flours of extraction rate less than National flour, to which vitamin B, nicotinic acid, and iron had been restored in the amounts specified in the Flour Order, 1953, which would significantly affect the health of the population in any foreseeable circumstances

The Government had decided to accept this conclusion as a basis for action The present Flour Order provided for the restoration of the three nutrients to all flour of an extraction rate below 80%, and to that extent was already in accordance with the main recommendation of the panel This Order would continue in force until the bread subsidy was abolished on Sept 29, 1956, when it was proposed to replace it by regulation under the Food and Drugs Act, 1955, and corresponding Scottish legislation, providing that all flour should contain not less vitamin B_1, nicotinic acid, and iron than the quantities laid down in the present Flour Order

The Government had decided to invite the Food Standards Committee to consider whether, in addition to requirements as to the content in flour of vitamin B_1 nicotinic acid, and iron, more extensive regulations governing the composition of flour and bread were needed to protect the consumer

Advice on Smoking

Replying to a question, Sir DAVID ECCLES, Minister of Education, said that a new edition of the Ministry's handbook on health education, containing suggestions for teachers, to be published shortly, would include a passage regarding advice to school children of the dangers associated with smoking

School Milk

Replying to a question Mr DENNIS VOSPER, parliamentary secretary to the Ministry of Education said that most pupils taking school milk at weekends were at independent boarding schools Very few children from other schools attended the special centres open on Saturdays and during holidays, and these centres were expensive to administer There was no good reason why pupils in nursery schools should have a larger allowance than pupils under five in nursery classes and ordinary classes

N H S Working Parties and Committees

In answer to a question, Mr R H TURTON, Minister of Health, gave the following list of working parties and committees due to report on the National Health Service

Mileage Committee —A report is in draft

Committee of Inquiry on the Rehabilitation of Disabled Persons —Report is expected later this year

Working Party on the Recruitment and Training of Health Visitors —Report has been received and will be published shortly

Committee on Hospital Supplies —An interim report is expected in June

Joint Subcommittee on the Control of Dangerous Drugs and Poisons in Hospitals —Report is expected before the end of the year

Study Group on Maintenance of Building Plant and Grounds —Report is expected shortly

Committee on Medical Manpower —Not yet known

Committee on Recruitment to the Dental Profession —Report is expected this summer

Working Party on Social Workers —Not yet known

Study Group on Application of Electronic Devices to Hospital Accounts and Costing —Not yet known

Committee on Maternity Services —Not yet known

Obituary

JOAN GRAEME MALLESON

M B Lond

THE news of the death of Dr Joan Malleson in a drowning accident in Fiji on May 15 was received in London last week To her work at University College Hospital and for the Family Planning Association and to her writing and broadcasting, she brought a clear unprejudiced mind and a ready yet discerning sympathy

Joan Billson was born at Leicester in 1900 and educated at Bedales, where she was head girl She qualified from Charing Cross Hospital in 1925, and after holding a house-appointment there she became medical officer to the comprehensive clinic at Holborn and later clinical assistant at the West End Hospital for Nervous Diseases Her experience in these posts and in the general practice which she ran for a number of years with the late Cecile Booysen convinced her that much of her patients mental and physical ill health was caused by sexual difficulties due to ignorance She believed that health education on marriage and the special problems of women would be the most useful contribution she could make to medicine, and her success in this work led her gradually to give up her general practice to spend all her time in this specialty Outside her consultant practice she was medical officer to the clinic for sexual difficulties of the Islington Women's Welfare Centre, and to the dyspareunia clinic at the obstetric unit of University College Hospital As a member of the executive committee of the Family Planning Association she gave evidence to the Royal Commission on Population and started the association's seminological centre She also wrote many of their pamphlets Under the pseudonym of "Medica" she wrote books addressed to women and married couples, notably *Change of Life* and *Any Wife or Any Husband*, and she gave an excellent series of talks in *Woman's Hour* on the problems of the menopause Her contributions to scientific journals included a paper in our columns in 1951 in which she suggested that in many affective disorders there were remediable endocrine factors For some years she had continued to work despite ill health, and last January she sought recuperation in an exchange of practice with a New Zealand woman doctor She was on her way home from this successful experiment, of which she had lately written cheerfully and happily to friends in this country

M C N J writes

'More than thirty years ago Joan Malleson and I—Joan Billson as she was then—were fellow students at University College in Gower Street, but we subsequently went to different hospitals and did not meet again for many years by which time we were both wives and mothers and back in medical practice Joan was in partnership with that forthright pacifist Cecile Booysen, by whom she was greatly influenced and to whom she was devoted Cecile's untimely and tragic death was a great blow to Joan and left a gap in her life which was never quite filled Not long afterwards she gave up general practice for consultant work of a kind in which her great gifts of sympathy and gentleness brought untold comfort to the many couples who came to her with their marital

Public Health

THE WORK OF A CHEST CLINIC

R. GRENVILLE-MATHERS
M.A., M.D. Camb., M.R.C.P.E., F.R.F.P.S.
MARGARET SHELDON
M.B. Lond
PHYSICIANS, HARROW CHEST CLINIC, MIDDLESEX

THE work of any institution must depend primarily on the demands made on it We therefore attempt here to describe the work of a chest clinic from the organisation of a particular clinic and from all the new cases seen there in 1954, in much the same way as has been done by Avery Jones (1953) for a regional hospital and by Gibson (1955) for a geriatric unit In this way, we hope, a composite picture of the function of the various units of the health service will gradually be painted

Patients

The patients seen in a chest clinic can be succinctly divided into tuberculous and non-tuberculous The chest clinic since 1948 has seen two simultaneous processes (1) a decrease in responsibility for non respiratory cases of tuberculosis (although contacts and other environmental factors are still dealt with), and (2) an increase in the number of patients with respiratory symptoms from any cause referred to the clinic The increase in the latter has greatly exceeded the decrease in the former

TABLE I—INCREASE IN NUMBER OF PATIENTS SEEN FROM 1950 TO 1954

—	1950	1952	1954
New patients referred to clinic	2264	5846	8496
No of persons radiographed	8121	13 813	18 877
No of X ray examinations (units)	21 612	29 917	39 285
Sessions held	988	1420	1630

Table I shows the increase in numbers referred to the clinic from 1950 to 1954 (when the attendances numbered 31,066)

Equipment

Since the chest clinic is increasingly being regarded as an outpatient department dealing with all respiratory diseases, it is usually equipped to deal with such diseases Thus, the building of the Harrow clinic, which serves a population of about 225,000 consists of a waiting-room, 18 dressing-cubicles, 3 consulting-rooms, and rooms for the radiological department general clerical staff almoner, health visitors, clinical investigations, and records

Radiography now plays a vital part in chest work, and the clinic has a four valve set with rotating anode tube, a tilting couch with tomographic attachment, and an 'Odelca' mirror camera for miniature radiography, Placed between two of the consulting rooms and accessible from each is a screening-room containing a separate X-ray screen, so that films of the patient can be supplemented by screening when necessary

The clinic also has spirometers for testing respiratory function and an electrocardiogram for differential diagnosis

Staff

The clinic staff consists of a medical team comprising a whole time consultant physician, assistant physician, registrar, and two part-time assistant physicians who between them hold five sessions a week in the clinic The whole time medical staff are also responsible for the ward care of patients in the associated hospitals, Edgware General and Colindale The remainder of the clinic staff consists of one whole-time radiographer, one part-time radiographer, a dark-room assistant, a trained almoner, four health visitors, an administrative officer, two medical secretaries, four other clerks, and a receptionist

Referral of Patients

Patients seen and examined by the medical staff may be referred by direct appointment by their general practitioners or come via the "X ray only" sessions (Trenchard and Grenville Mathers 1952) General practitioners are naturally reluctant to refer patients to a consultant for an opinion where respiratory symptoms are minimal or of short duration, but they welcome the opportunity for having a chest radiograph taken of the patient without the necessity for making an appointment

These radiographic sessions are held daily and usually last thirty to forty-five minutes Two views are taken of each patient with an odelca camera producing an image measuring 70 × 70 mm The films are read the following day, and a report is posted to the general practitioner Where abnormalities are seen an appointment is sent to the patient, and the referring practitioner is notified accordingly

This latter system of reference to the chest clinic, originally started as an auxiliary system, has now become the principal way by which patients are referred and is particularly valuable in detecting early cases of respiratory tuberculosis and bronchial carcinoma Thus, in 1954, only 280 patients were referred direct by their general practitioners, whereas 6041 were first sent to the "X-ray only" session

Whereas the mass miniature radiography units are now finding only 2 cases of pulmonary tuberculosis per 1000 adults radiographed, this session in 1954 yielded 17 cases of pulmonary tuberculosis, and 5 cases of bronchial carcinoma per 1000 adults radiographed, with an incidence of 62 per 1000 in men aged more than 45

In addition to the above methods of reference patients are seen in domiciliary consultation at the request of the practitioner In view, however, of the need for a chest radiograph in many of the latter patients, the practitioner concerned often arranges by telephone for the patient to attend the clinic by ambulance and stretcher

Such a system of working means that the work of seeing patients for the first time is quite onerous because the great majority have already been through a radiographic sieve and therefore usually have some definite radiographic abnormality

Other patients seen for the first time in the clinic include those referred by the directors of the mass miniature radiography units (56 patients in 1954) and those referred by colleagues in other departments

The full radiographic facilities of the clinic are also used for routine chest radiographs—e g, pre employment radiographs of management committee staff, annual radiographs of nurses, and radiographs of school entrants found to be tuberculin-positive At the request of the school medical department tuberculin testing of children is also done in addition to the routine tuberculin testing of all children referred to the clinic for the first time by general practitioners and school medical officers

New Cases in 1954

1602 new cases received full clinical and radiographic investigation in 1954 in addition to 965 new contacts of tuberculous patients Table II shows that 8496 patients were originally referred to the clinic and the number in each category of reference requiring to be recalled to the clinic for further examination The various diagnoses made in the 1602 recalled cases can be seen in table III, which shows a large group of unclassified cases, mostly in children The children were mainly referred for an opinion after a respiratory infection during the course of a specific fever Many of the adults in this most capable and intelligent young people Yet farming is an interesting, though hazardous, life Nature still largely governs the growth of crops and animals frost and tempest, drought and floods, inflict heavy loss, diseases and pests attack plants and animals Natural hazards are always upsetting the farmer's plans, and on occasion may ruin him They have not been and probably never will be controlled as closely as manufacturers can control their output The biological processes of gestation, birth, growth, and maturation take a long time, and crops and livestock production cannot be suddenly turned or stopped to meet market changes Farming is more than an occupation it is a family enterprise and a mode of life, which cannot be rapidly adapted

As this F A O booklet points out, farming and industry are not essentially in competition They are indeed partners In nearly every country, if industrial incomes are high, so are farm incomes, but, when industrial incomes are low, farm incomes are lower But whether a country be rich or poor, agriculture does not receive a "fair" share of national income If agriculture is to keep pace with the growth of increasing industrial populations, it must have both financial capital and intelligent leadership for its development

---

University of Cambridge

On May 12 the following degrees were conferred

M D—B A J Chodak Gregory R G Orr, C M B Pare, Matthew Wilkinson

M Chir—P F Jones

University of London

On Nov 23 the hon degree of LL D will be conferred on Sir Harold Himsworth

Mr J H Birkinshaw, D SC, reader in biochemistry at the London School of Hygiene and Tropical Medicine, has been appointed to the university chair of biochemistry at the *school* Dr B S Cardell, senior lecturer in morbid anatomy at King's College Hospital Medical School, has been appointed to the university readership in morbid anatomy at the school

University of Sheffield

Dr R A Caldwell has been appointed lecturer in pathology, Dr R S Duff lecturer in medicine, Dr J P Green, Dr A Simpson, and Dr R A James demonstrators in anatomy, Dr F J Flint part time clinical teacher in medicine, and Mr A A Jefferson part time clinical teacher in neurological surgery

University of Leeds

Dr C E Lumsden has been appointed to the chair of pathology

Dr Lumsden graduated M B in the University of Aberdeen in 1936 and later held house appointments in the Royal Infirmary there In 1938 he was awarded a Garden research fellowship in the university and he remained in Aberdeen until 1951 as an assistant lecturer and finally senior lecturer in the department of pathology He was released from the university at his own request in 1940 and served in the R A M C in India and Persia In 1948 he took the degree of M D with honours and in 1949 with a senior Rockefeller fellowship visited American medical schools In 1951 he was awarded the Royal Society's Henry Head research fellowship which he still holds The first six months tenure of the fellowship he spent working in the cytochemical division of the Carlsberg Laboratory Copenhagen He then joined the Institute of Neurology of the University of London and created at the Maida Vale Hospital for Nervous Diseases a small independent unit for research in experimental neurocytology

Faculty of Ophthalmologists

The following have been elected officers of the Faculty for 1956–57

President Dr John Marshall, vice presidents Mr J R Wheeler Mr L H Savin hon treasurer Mr A McKie Reid hon secretary Mr T K King

Symposium on Arteriosclerosis

The Swiss Academy of Medical Sciences is holding a symposium on arteriosclerosis at Basle from Aug 8 to 10 Further information may be had from Prof A Gigon Petersplatz 13 Basle, Switzerland

Nuffield Burns Unit

On May 12 this unit was opened in the plastic surgery department at Stoke Mandeville Hospital Aylesbury, by Sir Harold Gillies Immediately before the opening ceremony Lord Nuffield put the last screw in the plaque on the door of the unit which bears his name

Hunterian Society

The gold medal for this society's essay competition in 1955 has been awarded to Dr John Fry

Beit Fellowship

A junior Beit fellowship has been awarded to Dr R J Shephard

National Blood Transfusion Service

There were 759,371 donations of blood in 1955 compared with 700,202 in 1954 116,410 people gave their blood for the first time, and at the end of December the donors' panel was 591,204, compared with 540,389 a year before To meet the ever increasing demands for blood, the service needs at least 650,000 regular donors to make sure that supplies of blood are adequate Anyone who is in normal health and between the ages of 18 and 65 is welcomed

Dental Man-power in the Forces

The Ministry of Health and the Department of Health for Scotland, in consultation with the dental profession have appointed a Dental Manpower Committee to advise on the allocation and recruitment to the Forces of dentists liable for National Service Mr J P Dodds, of the Ministry of Health, is to be the chairman, and the medical members are Sir William Kelsey Fry, Mr F G Gibbs, Prof W E Herbert, Prof R V Bradlaw, Dr T H J Douglas, and Dr A T Wynne

Maternity Services Committee

This committee, which was set up by the Minister of Health under the chairmanship of the Earl of Cranbrook, to review the organisation of the maternity services in England and Wales held its first meeting on May 17, and decided to invite written evidence Invitations are being sent to selected organisations and the committee will also consider evidence submitted from any other source Any person or organisation wishing to submit views should write to the committee's secretary Mr J S B Butler, Ministry of Health, Savile Row, London, W 1

Treatment Centre for Spastics

On May 16 Miss Patricia Hornsby Smith, parliamentary secretary to the Ministry of Health, opened at Prested Hall Feering, Essex, the National Spastics Society's first residential treatment centre for adults The centre will take 30 men and women with cerebral palsy, between the ages of 25 and 40 The staff includes 2 physiotherapists, 2 occupational therapists a speech therapist, and house parents, under the guidance of Dr A G Mackenzie and Dr Nicholls Palmer Miss Hornsby Smith said that the society's record was a proud one In a comparatively short time they had opened 4 national school and residential centres and, in cooperation with local health authorities, 29 local schools and centres There was she believed, immense scope for voluntary effort on specific and numerically limited problems such as this "Anyone who imagines that the health service can do everything at once, is living in the realms of fantasy, and with the many vast problems with which we have to deal we can only fix our priorities and try and solve them within the limits of the financial allocation which Parliament allows us

Births, Marriages, and Deaths

BIRTHS

TURNER—On May 6 at Redwood City California to *Joan* wife of Robert G Turner F R C S a son James brother to Peter and John

Some patients are treated for respiratory tuberculosis ithout ever being admitted to hospital, although it is esirable that all patients should have a period in a hest hospital, at least during the time of up grading, n addition to those admitted for major surgical operaions In recent years there has been a decline in the opularity of minor collapse measures in the treatment f respiratory tuberculosis in favour of more permanent ollapse therapy, which obviates, for upwards of three ears, any need for weekly attendance for refills In pite of this the attendances at the refill clinics in 1954 ere 9262

Resettlement

In chest medicine the resettlement of the patient is utomatically considered as a routine part of treatment Fowler 1955), and whenever fresh employment is equired it is arranged through the resettlement clinic Grout 1952) The greatest difficulty is found in attempting to reable patients with chronic bronchitis and mphysema

Summary

An account is given of the staffing, equipment, and work of a chest clinic

The attendances in 1954 and the various types of chest diseases found are analysed

Attention is drawn to the striking increase in the number of attendances during the past five years and of the way in which the chest clinic is increasingly being regarded as an outpatient department dealing with all diseases of the respiratory tract

Centenary Celebrations

The centenary celebrations of the Society of Medical Officers of Health, held in London last week under the presidency of Dr C F White, included an oration by Lord Adrian, O M, an exhibition arranged by the Wellcome Historical Medical Museum, and a dinner given by the Corporation of London

LORD ADRIAN'S ORATION

Lord Adrian surveyed past achievements—work that cannot be fully indicated by statistics, since it has not only prolonged but also transformed our lives—and looked into the future, pointing to new fields for endeavour Much remains to be done, he suggested, in the field of mental welfare

"The problems raised by the village idiot the tramp, the feckless mother, and the idle apprentice have exercised social reformers and lawgivers without number Mental defective children must have been given a training more or less adapted to their capacity long before there were intelligence quotients and special schools with medical officers to send them there But past attempts to deal with social misfits have little to tell us about the kind of research we should undertake now Most of them were aimed more at the welfare of the community than at that of the individual With a more stable society we can afford to be more sympathetic to mental inadequacy, and we have come to doubt the efficacy of punishment in this world or of the threat of it in the next as a deterrent to faulty behaviour "

The results of mental-health measures were seldom as clear-cut as those of measures for physical health Reports on the former must be based much more on general impressions, and these would have little value unless they were made by someone with knowledge of mental hygiene and the time to study it There was a danger that, by too much insistence on measures that had not been well considered and by too much official visiting and advice, the mental health services might forfeit the coöperation without which they would certainly fail—cooperation from the general practitioners, the schoolmasters, the parents, and the public at large There was also a danger that too much insistence on mental health would raise a new standard of good—or rather of uniform—behaviour "We must aim at a stable and contented society but not one without the reformers and critics and eccentrics, the people who will not conform and are a nuisance to their fellows We must allow some revolt because our nature, as beings with human brains, ensures that we shall sometimes be discontented however wisely we are brought up, even though we are steered through infancy and adolescence with just the right amount of parental affection and the schooling which will make us responsible units in a democratic society "

EXHIBITION

The exhibition, at the London School of Hygiene and Tropical Medicine, is mainly retrospective, showing the society's progress over the past hundred years, but such retrospection is vastly rewarding From the first tentative beginnings in Liverpool, where the medical officer of health had to struggle not only with the immense difficulties of his task but also against personal poverty and public indifference, the exhibition traces, by means of pictures, diagrams, memoranda, diaries, and newspaper cuttings, the path to the modern health service Mr Punch's outbursts over the years—humorous, scathing, or indignant—are displayed to good effect

This admirable exhibition will be on show from 10 A M to 5 P M on Mondays to Fridays until further notice No doctor will fail to find here some item of interest to him

CITY'S DINNER

At the dinner, on May 15, the Lord Mayor observed that the post of M O H for the city, from which the society's president had just retired, was first occupied by Sir John Simon The Lord Mayor reflected that throughout the ages men had sought the right thing to say about doctors The work of those in public health was less spectacular than that of clinicians, but they could take pride in important achievements—for example, in the control of diphtheria and tuberculosis, and in promoting the health of children Dr White, replying for the society, admitted that Simon was not the first M O H his appointment in 1848 was just preceded by that of an M O H for Liverpool, but he would not hazard a guess whether that was because Liverpool was more enlightened or because it was dirtier Mr S E Cohen, chairman of the public health committee, proposed The Guests, and Mr R H Turton, the Minister of Health, and Prof C Fraser Brockington replied Mr Turton thanked doctors in the public health service for their cooperation in the programme for vaccination against poliomyelitis, but expressed concern at the unsatisfactory rate of immunisation against diphtheria As Minister of Health he was not concerned with all the M O H 's activities, for in 1951 (before the days of the garden of Eden) the Ministry of Housing and Local Government had been set up, and now he was not responsible for water or sewers The Lord Mayor responded to the toast of The Lord Mayor and Corporation proposed by Sir Allen Daley

Epidemic Keratoconjunctivitis on Clydeside

Since last November an outbreak of keratoconjunctivitis has caused considerable disability among workers in heavy industries on Clydeside The number of cases increased rapidly at the beginning of January, when there was a minor epidemic in a large shipyard, and the disease has since spread to involve other shipyards and industries Complement-fixation tests with the A P C group virus antigen showed significantly rising titres in 5 out of 7 paired serum samples taken in the early and convalescent phases of the illness Tests on 52 sera taken on the same day from cases of different durations, ranging from 1 to 112 days after onset, showed predominantly high titres after the 14th day but low titres before the end of the second week

These findings suggest that a virus of the A P C group is responsible for the outbreak Attempts to isolate and identify the serological type of virus involved have not yet succeeded hopelessly hurried and crowded, this experience has become dedicated to the 2nd M B It is no longer a foundation, either for practical purposes or for an education Preclinical teachers struggle hard against the difficulty of their scant numbers and their increasing separation from clinical work More enlightened perhaps than many of their predecessors, they try to inculcate an understanding of science and to stimulate their students' minds But outside the older universities and the schools that provide facilities for a B SC degree, these efforts influence only a minority of students Even where attempts have been made to reduce and select the content of the preclinical curriculum and where integration in teaching has been achieved, the examination is still the student's main objective and incentive, and unfortunately the student's concept of the examination is very different from the examiner's

I regard the second professional examination as one of the main reasons for our failure to adapt medical education to changing conditions and requirements It presents an official barrier to the integration of clinical and preclinical studies It imposes a time limit on preclinical studies so that the introduction of new basic disciplines such as psychology and social science is impracticable It prevents a reduction in factual and non-essential teaching such as is necessitated by dissection of the whole body Integration with the basic premedical sciences is likewise prevented, and this in turn has led to over-teaching of these subjects in the period which should still be devoted to general education The most serious indictment, however, lies in the attitude of mind it produces in the majority of students Because so many facts have to be assimilated in so little time, leisure has been eliminated If there is no leisure there is no time for thought, and if there is no thought there is no meaning in terms of subsequent experience *Too* many students still believe and hope they have "finished" with anatomy and physiology after passing the 2nd M B

But science itself has ignored the rigid barriers of the educational system Though medicine has not and never will become an exact science, it is now impossible for its practice to be good without the application of scientific method The effectiveness of this application will always depend on the doctor's understanding, imagination, sympathy, and moral integrity, but these attributes cannot make up for the absence of a scientific outlook Thus, to cope with the increasing complexity of medicine over the past twenty-five years, a sound clinical training demands a preclinical education, not merely as good as in the past, but considerably better

Clinical teaching —In clinical medicine factual teaching cannot be neglected or even selected to the same extent as it may be in the preclinical stages, for pathology, diagnosis, and treatment have a large factual content, and the student must at some stage strive to become acquainted with the whole truth in the branch of medicine he proposes to follow Yet some selection must be made, since nobody can now familiarise himself with the whole of medicine Professional competence and the advancement of knowledge both demand specialisation, and postgraduate training is therefore necessary for any kind of medical practice—including general practice which is one of the most difficult (and important) specialties

We might have expected, therefore, that for all forms of practice clinical training would have been separated into undergraduate and postgraduate stages, but there has been no real effort to make clear what should be done in each In face of a dual need of a more scientific approach and of more selective presentation of factual knowledge the undergraduate curriculum appears to have had only one consistent objective—to remain comprehensive

Specialisation Breeds Comprehensive Training

The reason for this is not hard to find So long a medical education adheres to the structure and organisation of fifty years ago, specialisation will continue t enforce an increasingly comprehensive training Almo every specialty claims some portion of the student time, and the process is cumulative because there is le and less overlap between special departments Thus th student's clinical experience is increasingly fragmented and though it is superficially wide it is seriously lackin in depth

From this stems a further trouble fragmented an distorted clinical experience, combined with an increa in teachers but a decrease in supervision, steadily under mines the apprenticeship system on which depends no *only* the vocational study of medicine but also th technical training in clinical method

It is frequently said that, if presented with a wid field of clinical experience, the good student will select for himself But there are different types of experienc appropriate to different stages of development Th student naturally feels that he would like to know everything, and the comprehensive final examination —for many students an external one—leaves him with little choice of what to leave out

It is apparent, therefore, that in both the preclinical and the clinical fields rapid expansion of knowledge, with all the consequent changes in medical practic have produced serious changes in medical education largely because our system of teaching and our method of examining have by comparison remained static

The Past Twelve Years

These observations are not new About a decade ago there appeared a number of detailed and objective assessments of the state of medical education All stressed the same things—the need for a basic rather than a comprehensive curriculum and the need to give undergraduate students an education, not merely a training, in medicine

Few reports have made this more clear than that of the 1944 Planning Committee of the Royal College of Physicians[3] "Medical Education" said this report "is directed towards two objectives which may be termed educational and vocational"

> In education we seek to train the student so that he can collect, analyse and interpret facts for himself, to observe and to understand what he observes *It is an objective* common to all University education in natural science and in pursuing it, medical education is peculiar only in selecting material for study that is relevant to the *problem of dis* The goal of this aspect of medical education is to produce men who are equipped to learn both by *their own experience* and that of others and who will continue to develop even when they have left the school in which they were taught Vocational training, on the other hand, aims at giving the student such a basis of knowledge as will enable him to practi Medicine on his own account It seeks to ensure that the medical graduate knows enough to *recognise* the *common* forms of disease and how they are treated

This committee drew attention to the inevitable conflict between the two objectives Describing the overcrowding *of the curriculum* by the attempt to include it in all knowledge before qualification, it said

> The result is that to an increasing degree during th clinical period the student's time and energy are taken up in absorbing an enormous mass of facts, *so that he can giv* no thought to the scientific principles underlying Medicine Students of exceptional ability may survive the ordeal with no more serious consequences *than fatigue* but the average man usually seeks the easiest way *out of* his impasse and accepts that the primary *object of* his training is to absorb as much information as possible"

---

[3] Royal College of Physicians Planning Committee's Report o Medical Education 1944

The other group of people whose health is endangered by our present way of living is men of 45 to 64 Coronary thrombosis and cancer are "the leading causes of death" among these men Illness among employed people has increased steadily since 1952, and the figures for 1955 show an increase of 9% over 1954 Tuberculosis was still the most important cause of loss of time at work, though notifications continued to fall—to 128 per 100,000 of the population, which is a reduction of 7% on the rate for 1954 The number of people on the waiting-list for admission to sanatoria had fallen from 515 in 1954 to 148 at the end of 1955 This fall is not matched by the fall in notifications, and the improvements in the hospital position is partly due to the increasing efficacy and use of domiciliary and outpatient management

The blue-book also includes the report of the Scottish Health Services Council and its standing advisory committees

Occasional Survey

ANKYLOSING SPONDYLITIS

In a comprehensive review Blumberg and Ragan[1] remind us that this disease was first described by Bernard Connor Born in Ireland in 1666, Connor published in 1691[2] a description of a skeleton with spondylitis—an "extraordinary humane skeleton, whose vertebrae, the ribs, and several bones down to the os sacrum, were all firmly united into one solid bone, without joynting or cartilage" From the time of this description the emergency of ankylosing spondylitis as a specific entity was retarded by confusion with other conditions, notably with degenerative joint disease of the spine with senile kyphosis In the United States the disease being generally regarded as a form of rheumatoid arthritis, goes under the name of "rheumatoid spondylitis" In this country most clinicians prefer "ankylosing spondylitis," and would agree with Hart[3] that "in the meantime it is, perhaps, more profitable to study these disorders as different unsolved problems than to put them all into one diagnostic cauldron" The syndrome, by whichever name it is known, still lacks complete uniformity and atypical cases have quite recently been distinguished Buckley[4] held that the predisposition of ankylosing spondylitis to attack men more than women, its characteristic tendency to produce bony ankylosis, its centrifugal spread. and its failure to respond to gold, made it unlikely to be a variant of rheumatoid arthritis To these points may be added the responsiveness of ankylosing spondylitis to treatment with X rays (at any rate in terms of relief of pain) and the rarity of a positive differential agglutination (Rose-Waaler) test (which was positive in only 3 of Ball's 203 cases[5]) The only good evidence for the opposite view is that peripheral joints may be involved and that the histopathology of the diarthrodial joints of the spine is strikingly similar to that of rheumatoid arthritis Cruickshank[6] found certain minor differences, there was a greater liability to haemorrhage in ankylosing spondylitis (perhaps a result of the earlier formation of adhesions and their rupture by movement) and a tendency to thickening of small vessels, usually in the form of endarteritis obliterans He argued that the histopathology of rheumatoid arthritis is not entirely specific, and that a similar picture in ankylosing spondylitis need not imply a common aetiology Subcutaneous nodules—lesions much more specific for rheumatoid arthritis—are unknown in ankylosing spondylitis van Swaay[7] proposed a different view of the pathogenesis of ankylosing spondylitis, believing that the essential process in the sacro iliac joints is a proliferation of new cartilage, which replaces the old without evidence of inflammation The joint-space is finally ossified.

The cause of ankylosing spondylitis remains unknown Various agents have been suspected, including tuberculosis, brucellosis, and gonococcal infection These conditions can certainly produce lesions in the sacro iliac joints which in some ways resemble those of ankylosing spondylitis, but they cannot be accepted as aetiological agents Parathyroid dyscrasias, genito-urinary disease allergy, and metabolic and hormonal factors have all been put forward, but none has been convincingly established Several groups of workers[8–10] have failed to confirm the finding of Davison et al[11] that the excretion of 17-ketosteroids is increased in ankylosing spondylitis Inheritance is known to play a part, and Hersh et al[12] decided that the factor involved was an "autosomal dominant which has about 70% penetrance in males and about 10% or slightly greater in females"

Diagnosis

In many cases the diagnosis of ankylosing spondylitis is not difficult, and a story of pain or stiffness in the lower back or buttocks (perhaps with sciatic radiation) in a young man raises immediate suspicions The lumbar segment of the spine should be examined for flattening and loss of movement, and the chest for impaired expansion[13] X-ray examination of the sacro-iliac joints is essential and a normal erythrocyte sedimentation rate should not be accepted as excluding the diagnosis There are, however, important deviations from the classical picture In Hart's series[3] the earliest symptoms in 13% of patients were in the peripheral joints, and there was swelling of these joints in over 20% The knees and ankles are most commonly involved and the distribution of affected joints is rarely that of classical rheumatoid arthritis For example, the wrists were involved in only 7% of Blumberg and Ragan's cases and the hands usually escape Iritis may be the presenting sign, and this again helps to differentiate ankylosing spondylitis from rheumatoid arthritis, in which lesions in the eyes, if present, are those of episcleritis or keratoconjunctivitis sicca In Blumberg and Ragan's series 25% of patients had one or more attacks of iritis during the course of their disease, and this complication was often the only reason for admission to hospital and for treatment with hormones In this country iritis has been observed in 6–24% of cases[14–17] Pain over the angle of Louis is not uncommon, and Savill[18] described a sequence of radiographic changes starting as erosions of the bone ends and ending in bony ankylosis Changes in the manubriosternal joint may however, be found in rheumatoid arthritis Among other features of ankylosing spondylitis, tenderness over bony prominences notably the ischial tuberosities and iliac crests is common[10], and the radiographic accompaniments are irregular lytic defects with a punched out appearance, irregular zones of increased density and "whiskering" or ' fringeing" to say whether this has improved the quality of medical students There is in fact no means of comparison Almost all the factors affecting students have changed, and I personally believe that we have very little accurate information about the students in our schools

Although selection has been widened in one way it has been restricted in another The academic requirements for entry into universities have been raised, and the average student does not complete them until the end of his school career after a two-year course of study For almost all who wish to take up medicine, this study is limited to subjects of the 1st M B examinations, for not to limit it in this way would prejudice the student's chances of passing the 1st M B, even after a year's course at the university But studying even two scientific subjects up to advanced level in the General Certificate of Education seriously reduces the opportunities for studying any other subjects Although the scientific sides of all public schools and grammar schools have been strengthened since the war, it is difficult for these schools to provide classes in which general education can remain balanced and at the same time the examination requirements be satisfied

Moreover, it is natural for boys and their parents to argue that if two thirds of the 1st M B examination can, and virtually must, be passed from school, then the only sensible course is to complete the 3rd part also, and thus avoid a year at the university devoted to the study of one subject In consequence it has become common practice for future medical students to devote the last two years of their schooling to chemistry, physics, and biology almost exclusively Direct entry to the preclinical department of the medical school is now common and is increasing For twenty years it has been the standard procedure at the University of Cambridge, which requires that these parts of the 1st M B should be passed before entry

The importance of a good general education to those who are to be doctors has been stressed repeatedly Although some have wished to exclude science, the majority regard a good education as a *balanced one* The deplorable fact is that medical students now have a less balanced general education than ever before Many in fact cease to have any non scientific education at all after the age of 16

This unrelenting demand for a high examination standard in the premedical sciences has hampered good scientific education Except in schools with an unusually large science staff, it is almost impossible for the average boy to gain a sound scientific understanding and at the same time acquire the amount of factual knowledge required to take three (in London University until recently four) subjects at advanced level The premedical examination is, however, an inflexible criterion of selection, and it ensures that, from the age of 16, prospective medical students are conditioned to factual teaching for factual examinations At each later stage of the curriculum this conditioning process is continued and reinforced

I am unaware of any figures showing what proportion of candidates selected by medical schools on grounds of character and personality are later refused for failing to pass the 1st M B I doubt whether anyone can assess what some of those who pass and enter have forgone in their last two years at school in order to get through —the athletic activities that have been given up, the general reading that has been abandoned, the prefectships that were not taken up or not taken seriously Positions of responsibility at school are of inestimable value to boys who are destined to have very little responsibility in the later years of their professional training

Grants and Examinations

The majority of medical students are to some degree State supported by grants With these grants and family help some are comparatively well off while others manage moderately well with part time paid employment Others are quite comfortably supported financially by a combination of a grant and a wife who is earning A comparatively small number, with no grant or only a minor one, exist at subsistence level only In all cases, however, the financial implications of examination failure are very serious

Most grant giving authorities are, in my opinion, very sympathetic to their medical students, but some naturally have difficulty in realising that a degree course in medicine is not comparable with a degree course in, for example, history There is no honours degree course in medicine it is a matter of pass or fail in the examinations, and during the past five years the failure rate in London University's final M B —an external examination—was between a third and a half of those making their first attempt The situation is not much different with the external qualifying examinations of other licensing bodies Thus for a not inconsiderable proportion of medical students the clinical curriculum is prolonged for six months beyond the accepted course—even if they pass the examination at the second attempt

To the grant giving authorities this high failure rate is both baffling and expensive, and at least one county council has notified students that failure in the examination will be immediately followed by withdrawal of the grant This situation inflicts a grave injustice on many students, and, apart from the anxiety occasioned, it has further repercussions For a large proportion of grant aided students take the Conjoint diploma in addition to the university degree as an insurance against M B failure and loss of grant This procedure not only adds to the financial strain but also interferes seriously with the third year of clinical training, for the idea that students take these extra examinations merely for practice, without specific preparation and without undue concern is, in my experience, largely a myth There is no more lamentable facet of medical education in this country than the double external qualifying examination

The Student's View

With this atmosphere of learning in mind, it is worth trying to envisage the medical curriculum as it may appear to an average student

He comes to his medical school armed with whatever general education he had acquired on reaching the age of 16—to which he has added remarkably little since either from learning or from experience of the world He has spent up to three years on the study of chemistry, physics, and biology He then spends about two years on isolated study of anatomy, physiology, biochemistry and (if he has to pass an examination in it) pharmacology He often gains no knowledge of psychology except that given him by his own experience and his inherited intuition

When he comes to clinical studies, he rarely has any knowledge of pathology, he has seldom acquired the art of learning (being accustomed to the acquisition of knowledge by memorising, and relying mainly on didactic lectures and textbooks), and his critical faculty has seldom been awakened He is enormously relieved that he has no further important examinations to face for nearly three years and he is prepared to take things more easily Nevertheless he starts his clinical work with enthusiasm This, he thinks, is the real thing he *is going to deal with people*, and he usually believes that work will now be much more stimulating and much less difficult The stimulation of the live patient lasts for some time, but medicine soon begins to appear extremely vague and muddling and often most disappointing There seems to be no sure basis for it all Pathology, which might give him this, seems to him (if indeed he meets it at all in the early months) a very strange subject with a terminology that he does not

In England Now

A Running Commentary by Peripatetic Correspondents

MOST people think that working in an international organisation is an opportunity for learning foreign languages But how many realise that it is also an opportunity for rebuilding one's own ? For these organisations are laboratories in which the English of the future is being designed In their documents new words are continually being coined, tested and then either adopted or discarded Did not the word " global " itself (as opposed to globular) spring from the United Nations ?

Some words fulfil an obvious need What could be neater than ' two suitcases were completely unreusable,' " the recruitment of a nurse is being pended for the time being," or " supplies and equipment were still packed in their cases and no head or tail could be made out of them " What could be more natural than that a statistical report should be submitted for ' multiplying " ?

But telegraphese is less attractive, and I hope that the English language will never accept such concise phrases as " please onforward the finalised planops or ' in view of criticisms by the Government of article v the plan of operations is returned herewith for refinalisation " Undoubtedly international medicine is an etymological paradise

* * *

Bed rest has enabled me to plan the sanatorium of the future, full of happy patients, dedicated doctors, and satisfied administrators

The large main block will face south, overlooking a large lawn, sloping away to a background of trees In the centre of this is a circle of stone seats enclosing two large flat stones, with, to the south a double archway arranged so that the sun, striking through it, falls on the two stones at the summer solstice and at the vernal equinox Every patient's bed would have a direct view In the admission block, the patient will be prepared for entering the community Brain washing coupled with the gradual severing of family ties and the discontinuance of visiting will take place simultaneously with the provision of a suitable substitute for the family inside the sanatorium—for example, for father, the physician, for mother, the ward sister, and for mother in law, matron A sibling of the same sex would be an up patient, while the trained sublimation of sex will be a major source of strength to the community

At each full moon there would be an initiation ceremony, at which the neophytes, sponsored by their new family, would enter the community and be conducted to their new bed in the main block Details of the ceremony could be varied in each sanatorium, but the style would be a mixture of the best of Wilfred Pickles and Aimee Macpherson At monthly psychi surgi soma therapy ceremonies patients who needed a decision as to treatment would sit round the circle, holding their latest film. Presiding at this, as at all big moments in the community life, will be the archetypal figure of the fully gowned and masked thoracic surgeon. As each patient holds up his film, he will cast different coloured stones on to the ground out of urns placed on the flat stones, and will interpret the message they give Thus, for example

> This is the treatment we dictate
> For the patient admitted to room number eight
>
> Three months horizontal he will stay
> Bar using a bedpan once a day
> Lower his head and raise his toes
> Thus his cavity will close
> Daily strep and INAH give
> To keep his T.B sensitive

Once a year, at the vernal equinox, at a ceremony of rebirth, patients will be chosen for discharge They will immediately change their up uniform for their own clothes and be withdrawn to the discharge-block, there to undergo the reverse of the admission process For instance, the thoracic surgeon would appear to them for the first time in ordinary clothes The umbilical cord chaining them to the community would thus be cut, and visits from families encouraged On midsummer day a maypole would be erected, and at the moment of the solstice, the ribbon cut by the chairman of the management committee Patients for discharge would dance with their children to symbolise the reunion, and at the end of the day would return home.

Let no-one think the Medical Research Council is forgotten Its statistical committee could control the colours of the stones in the urns, and a controlled series of surgical cases, alternately chosen by the oracle or by the physician, would give rewarding results

The other day while using that Middle Eastern instrument, the shuftiscope, to inspect the mucous membrane of the distal colon, I was idly speculating on the -scope end of the word and wondering how the stethoscope came to be so named What did stethos mean ? Despite a highly prized classical education up to VI form standard, I had not met this obviously Greek word as far as I could remember A little research in *Chambers's English Dictionary* told me that it meant ' breast " Obviously, the early single-tubed instrument was not really suitable for inspection of the breast, as the small hole would give a limited monocular view and some time would be needed for a proper inspection of the whole area It would of course be an admirable instrument for patients who expect a full examination through the aperture made by undoing one button It was then found I suppose, that one could listen to heart and chest sounds while carrying out this tedious inspection Some inventive fellow, no doubt, then thought out the instrument with two ear-pieces, increasing the efficiency of inspection of the breast by allowing the use of binocular vision over a larger area than was possible before and also making feasible auscultation of heart sounds at one and the same time

I feel that as its secondary use as an aid to hearing rather than vision now takes precedence it should be renamed, and I shall rename mine a cardiophone On second thoughts I am really much more interested in gastro enterology, and as the first to draw attention to this obvious misnomer, I shall claim the right to have it called a borborygmiphone More impressive in front of the patient, too, and—better still—a Greek ending on a Latin stem. There's too much of this rampant Nationalism these days I'm all for coexistence

* * *

Wallpaper blisters when it is applied by the amateur, even when one of the new plastic substitutes for flour-paste is used exactly according to the maker's directions Most of the blisters disappear spontaneously as the wall dries out, but a good-quality embossed paper in the drawing-room let us down badly It wasn't only blistering the edges lifted where they should have stuck firmly There was consternation and disappointment in the house, but from the depths of despair the ' needling technique " was born

A 3 c cm. syringe with an exploring needle can be filled with plastic substitute if the plunger is pulled hard The long needle slips under the lifted edges of the paper and the required amount can be injected easily A moment's pressure and a wipe from a clean rag sclerosed the first blister beautifully, so the remaining lesions were treated to a surgical approach.

The technique was one of subcutaneous infiltration From one puncture, adhesive could be infiltrated between paper and wall over most of the separated area and it was found that 2–3 c cm was required for the larger lesions Pressure was applied by junior members of the family and a flat smooth surface was the first result Tomorrow we shall know if there has been recurrence or relapse

My long preparation for the final M B has resembled an Orwellian brain-washing, for I have been conditioned to accept oft-quoted dogma Thus I carefully palpate for the inferior epigastric artery, sagely oscillate the vertex in vertical polarisation, and, following the lead of the Professor of Surgery, I say " Yes, Sir, direct I think " I had become reconciled to the specious self-deception involved in the detection of such outlandish signs But now, the awful truth is revealed the course of brain-washing is utterly complete Today the Professor of Surgery invited me to palpate, and clearly and unmistakably I felt the inferior epigastric artery 1984, and I have arrived

* * *

Patient When I swallow, food seems to stick in my sarcophagus

Doctor Well that's your funeral

The other major reform, and one of very great educational potentialities, is the institution of the preliminary-registration year of hospital appointments under supervision This year is now an officially recognised part of the undergraduate curriculum During the three years of its operation, however, no serious attempt has been made to integrate the special experience of this period with the rest of medical training In effect, the qualifying examination forms a barrier to educational continuity at *this* stage just as effective and as harmful as that which the 2nd M B interposes between clinical and preclinical teaching It must be remembered that, although the universities have the responsibility for approving these posts and for certifying that the student carries out his preliminary-registration training satisfactorily, it is the hospital authorities that make the appointments and pay the salaries Between the two there is at present no adequate liaison, and in making the appointments and deciding the character of clinical experience which they provide, the needs of hospitals for "pairs of hands" play a far greater part than any educational considerations

In short, the primary reforms which have been made in the past ten years, in face of rapidly changing conditions, have been well conceived and were potentially effective, but they have not brought any appreciable relief because the system itself is outworn In the apt words of Prof Clifford Wilson "The old tree creaked before, its branches were overgrown and its roots insecure It needed drastic pruning and the fertilisation of new enthusiasms and ideas Instead it was given a number of grafts and they have not taken very well"

Medical Education in America

It was against this background that I visited last year a number of American medical schools, and from what I saw I should like to single out some features which seem particularly relevant to our present situation Although the growth of medical education has been much more rapid and diversified in the United States than it has here, we have much in common in our aims and methods of thought—largely because of the constant interchange of ideas between our two countries

In the first place I was impressed by the intense awareness of the problem of medical education In the individual schools both staff and students are actively interested in its improvement, and the great foundations are stimulating and supporting research into educational methods

As far back as 1924, a situation in many respects comparable to our own of today led the Association of American Medical Colleges to establish a national Council on Medical Education Serious problems had arisen through the combined effects of rigid controls and excessive specialisation At its first meeting the council decided that the immediate need was "to secure relief, if possible, from the restraint and burden of external regulations"[5] It is no doubt this early conviction which is responsible for the striking differences which now exist between the American medical schools and our own in the opportunities and freedom to experiment Not only have there been radical and novel experiments in certain centres, but even the older and more conservative schools have been able to make big changes when the need arose One of these has been the virtual abolition of the final examinations at the end of the clinical course Educational continuity is thus encouraged, and is further supported by the considerable efforts at integration in the earlier stages Throughout, joint teaching sessions and conferences are far more numerous than in this country

A most important factor is the proportion of his time and energy which the clinician spends in hospital In the U S A the "geographical full time appointment" has been deliberately encouraged and is now common in the main teaching centres Thus clinical conferences, combined rounds, and group discussions offer far greater opportunities than we enjoy for the exchange of ideas and information No less important is the much closer personal contact between student and teacher The student is taught as an individual rather than as a member of a heterogeneous group, and individual assessment of progress is made periodically before he proceeds to the next stage He is, of course, older than his counterpart in this country having had a longer premedical education, and he has at least that added maturity which develops so rapidly at this period This partly accounts for the fact that he works much harder than the English medical student, shows far more interest, and is more critical in his approach He is given time for special study of his own choosing and often undertakes minor researches Examinations play a very small part in his incentives, which seem to derive mainly from a genuine and active interest in his work

Experiments in medical education are difficult to assess and easy to criticise Whatever they do or do not achieve, they bestow an undoubted benefaction on a medical school in the enthusiasm and sense of joint endeavour they produce in both students and staff A study of medical education in the United States at the present time can be most rewarding It helps us to recognise more clearly what we must do to retain and strengthen what is good, and to eradicate what is bad, in our own system

(To be concluded)

PARITY AND THE INCIDENCE OF DIABETES

D A PYKE
M B Camb, M R C P
SENIOR MEDICAL REGISTRAR,
RADCLIFFE INFIRMARY, OXFORD

It is a common observation that more women than men have diabetes mellitus In youth there is little difference in sex incidence, but after about the age of 45 a preponderance of women appears, and from that age onwards women outnumber men by at least three to two (Harris 1949, Joslin et al 1952) Various reasons have been suggested for this difference, in particular that it may be because more women than men are fat, and that it may be related to the menopause (Joslin et al 1952 Bartels 1953)

I report here a survey of the patients attending the diabetic clinic at the Radcliffe Infirmary in relation to

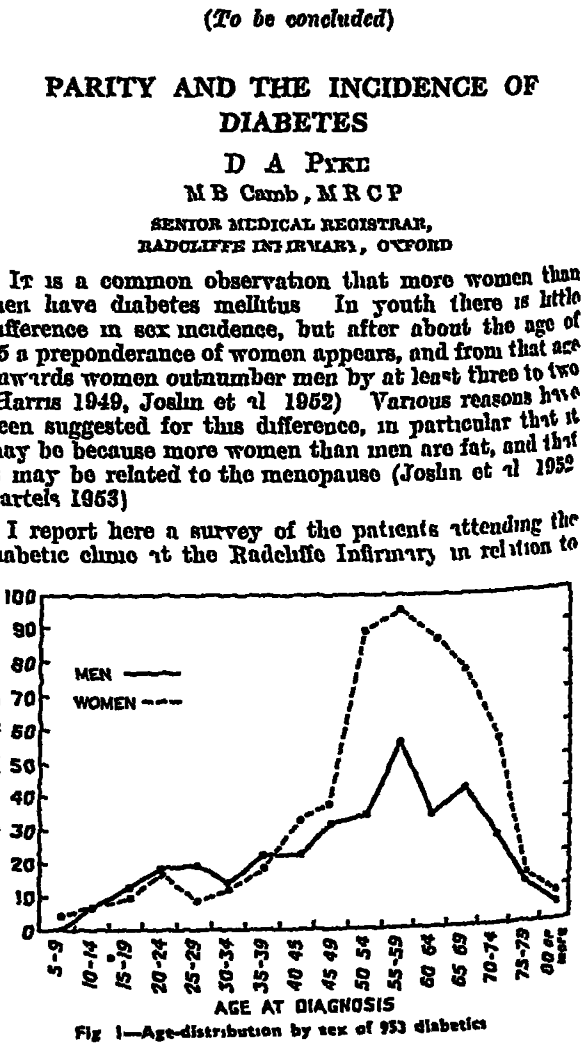

Fig 1—Age-distribution by sex of 953 diabetics

practice them in the home and they will realise how their education has been lacking

Castle Bromwich H M KENT

SIR,—I should like to congratulate Professor Russell on his article This must be an encouragement to the many who are struggling to cope with these problems, which are becoming increasingly acute

May I underline one pressing problem? There is a nation-wide shortage of trained midwives, which may be fatal to a service which is based on the work of this important group of women I do not myself subscribe to the concept of the midwife working in "glorious isolation," but regard her as a key member of the obstetric team As such, her status, privileges, and pay should be such as to support her pride in herself and her work Urgent attention needs to be given to this matter

Ashton under Lyne General Hospital T B FITZGERALD

REVISION OF THE CURRICULUM

SIR,—From reading the memorandum and correspondence in your columns, and attending meetings where medical education is discussed, the uneasy feeling emerges that most teachers and all administrators are taking themselves too seriously They ignore the proportion of the burden of learning which is carried by the student himself, teachers may make it easy or attractive for him to learn, but make him learn they cannot (neither for that matter can they stop him so doing) The essential personal nature of interchanges between teacher and student can be little altered by juggling with the times at which they meet, and thus playing about by administrators also obscures the real crisis facing medical education in the next few years—are we attracting a high proportion of the most capable and intelligent schoolboys? This vital problem is not controlled by selection, which filters out the worst If we do not attract the best, no change in the curriculum will matter much in the face of this defeat, if we do attract them, the student quality will be such that it will be immaterial what the curriculum is like

Is it the wisest approach to the new curriculum to turn the world upside down because there are unsatisfactory regions of it? It is doubtful whether the G M C will willingly surrender their authority, or in other words surrender us to the pleasure of a small group of enthusiasts (some would say fanatics or cranks), the names of the members of the R C P committee were not given in your summary of their memorandum, but one has doubts how widely representative this body is of, on the one hand, the basic sciences and, on the other, of the medical schools outside London The memorandum too asks for the blankest of cheques—the intentions of the new schools are not even sketched out in outline Even if the G M C surrenders, there are university and medical college boards to be circumvented, how will students belonging to two schools—the Oxford and Cambridge students doing their clinical work in London—be catered for if there is a difference in plan between these places, as is not unlikely? Are 57 varieties of medical education to be allowed, some of them canned?

Surely the wisest and quickest and least disturbing course is to seize on all commonly agreed points and act on them—good strategy to reinforce strength "Basic training" is not so agreed (is it principles, or general practice?), neither is a "good doctor" (should he be all head, is it permissible for him to be all heart, or must he be both?) But the synchronisation of related studies and the reduction of factual knowledge as such can be achieved inside the present G M C framework by discussion and arrangement between the individual subjects concerned I do not believe, either, that the present professors in preclinical subjects do in fact demand gross factual knowledge, this excessive demand for facts exists more in the imaginative memories of clinical professors than it does in real life Even so, some strenuous learning in the preclinical phase does not seem quite out of place, if only as an exercise ground and a selection hurdle

A further point arises from the loose use of the term "experiment" This word implies an investigation trimmed down to one essential point, at the end of which an accurate quantitative evaluation will emerge, preferably answering the question "yes" or "no" No rat is killed except for such an answer, but no such evaluation of the results of medical education is feasible, and we cannot write off five years and a batch of medical students in a proceeding for which we would not kill a rat Instead of experiment it were fitter to use the term "trial", it has two meanings

I should not write this except that as a pathologist I see a good deal of both the clinical and preclinical sides, and as a very young teacher myself I have not entirely forgotten or lost contact with students There are *too* many elderly men only too ready *to* dictate in matters which the present generation of teachers and students are perfectly capable of taking in their stride, as we did ourselves not so very long ago The present G M C rule may be somewhat inert and imperfect, but it is not illiberal, but the busybody goes about with a net of iron

London Hospital, E 1 J W LANDELLS

EXTRADURAL HÆMATOMA

SIR,—I read your annotation of May 5 with interest There are certain points, however, which I consider ought to be stressed with regard to this condition

The diagnosis of surface clot compression of the brain is essentially a *clinical* diagnosis In those cases where there has been a latent period, the development of severe headache with mental confusion, drowsiness, or giddiness should at once arouse suspicion of intracranial hæmorrhage, whether associated with bradycardia or not The quality of the headache in extradural hæmorrhage is unmistakable

Lumbar puncture and spinal manometry should be unnecessary in the ordinary case It is a dangerous procedure It is of value only in those few cases which develop slowly and insidiously over many days or weeks, with minimal neurological signs and little or no alteration in consciousness

Radiographs of the skull are useful only if they can be obtained quickly, the chances of survival are jeopardised by delay from any cause Delays in hospital can be just as serious as delays in transportation Speed is the keynote in the handling of this type of case

Local bruising of the scalp is one of the most valuable lateralising signs, provided the possibility of contra coup hæmorrhage is borne in mind, it does occur, as do bilateral extradural hæmorrhages

If for any reason operation cannot be performed under local anæsthesia, then general anæsthesia will have to be employed Unskilled anæsthesia which gives rise to increased venous congestion of the brain may precipitate a tentorial herniation

Rowbotham's figures[1] and my own[2] show a recovery rate of approximately 80% in this condition In the past five years I have seen a further 31 patients with extradural hæmorrhage in the neurosurgical service here 5 of the patients died, and thus the recovery-rate was over 80%

2 young adults died during transportation to hospital A young baby was decerebrate on admission and died after operation Another patient had a posterior fossa clot which had been developing over two weeks, the patient was

[2] Whalley N *Brit J Surg* 1949, 37, 212

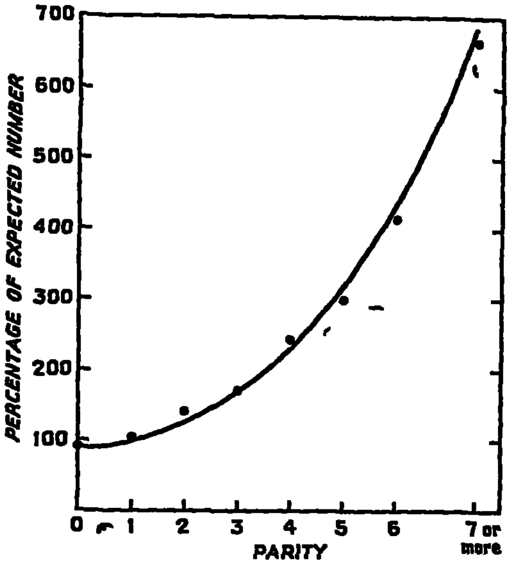

Fig 2—Increase of incidence of diabetes with parity in women aged 45 or more

This figure increases to nearly 50% for women who have borne two children but thereafter remains roughly the same for the higher parity groups. The difference between the nulliparous and highly parous women *expressed in this way is much less than the difference* between their relative incidence of diabetes.

Furthermore, as shown in fig 3, the relative increase of women diabetics with age is as pronounced among the normal and underweight as among the overweight.

Discussion

That the sex difference in the incidence in diabetes is confined to married patients was observed over twenty years ago by Mosenthal and Bolduan (1933), who attributed it in part to "the injurious effect of pregnancy upon the carbohydrate tolerance." Joslin et al (1936) confirmed this observation and attributed the difference mainly to a greater tendency of married women than single to become fat. They thought that the increased incidence of diabetes among middle aged women "reflects the strain on the endocrine system during menopause."

TABLE VII—INCIDENCE OF OVERWEIGHT IN RELATION TO PARITY

Parity	No of women	Percentage overweight
0	91	31
1	69	36
2	89	46
3	58	53
4	44	16
5	27	58
6	25	61
7 or more	60	41

Munro et al (1949) found that the large excess of women over men among their patients aged more than 40 (719 women, 239 men) was confined to married women, and that the difference could be "related, at least in part to previous childbearing," because they found more mothers of large families among their patients than were expected. These workers thought that marriage and childbearing did not affect the age of onset of diabetes or its severity, judged by tendency to ketonuria.

The present study suggests that the effects of parity are alone enough to account for all the true difference in the sex incidence of diabetes. This finding is in harmony with the views of Hoet (1954) and Jackson (1955), who regard pregnancy as an important provoking factor in a patient who is potentially diabetic. It is curious, if this is true, that pregnancy should lead to the development of diabetes, or rather its diagnosis, only some decades later, and that parity does not lead to the earlier appearance of diabetes. Nor does parity explain the apparent increase of diabetes among women in this century (Harris and McArthur 1952).

The greater tendency of multiparous than nulliparous women to become fat does not appear alone to be enough to explain the large number of multiparæ, because (1) there is a preponderance of women diabetics aged more than 45 even among those of normal weight and those under weight, and (2) the number of multiparæ who are overweight, though greater than the number of nulliparæ who are overweight, does not appear to be enough to explain the large difference in the incidence of diabetes among multiparæ and nulliparæ. Figures for weights of normal women also show a relatively small increase with parity (O'Brien and Shelton 1941).

That the menopause is not an ætiological factor of importance is suggested by the fact that there are no more nulliparæ aged more than 45 among the diabetics than are to be expected among the general population. If the menopause were a significant factor, an excess of women would be found in all parity groups, including the nulliparæ.

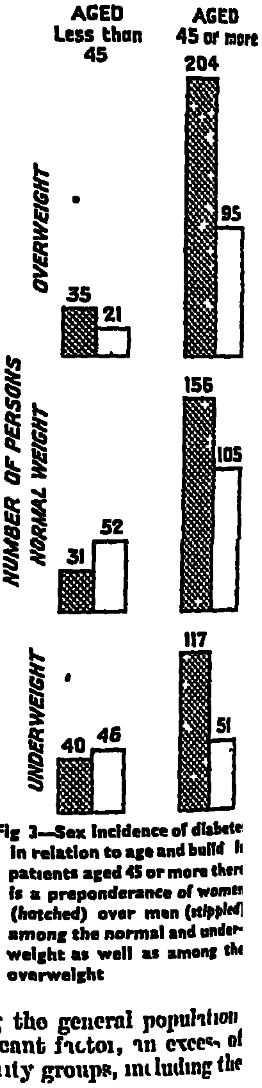

Fig 3—Sex incidence of diabete in relation to age and build I patients aged 45 or more ther is a preponderance of wome (hatched) over men (stippled) among the normal and underweight as well as among th overweight

Summary

An analysis of 953 diabetics shows an approximately equal sex incidence under the age of 45 but a preponderance of women over 45.

Part of this difference is due to the excess of women in the general population. The rest of the difference can be explained by the effect of parity. The excess of women diabetics is confined to women who have borne children and rises with increasing parity. A woman who has had five children appears to have about three times as great a chance of developing diabetes as a woman who has had none; but parity does not lead to the earlier appearance of diabetes.

This effect of parity cannot be due merely to a slightly greater tendency of multiparæ to become fat, since the preponderance of women diabetics is found among those who are of normal weight and the underweight.

Likewise, if the menopause were an ætiological factor of importance, an excess of women diabetics would be expected in all parity groups, but this is not the case.

I wish to thank Dr A M Cooke for help and advice, Mr B Merry and Mrs M Eastway for hours of laborious clerical work, Mr J H Luck, records officer of the Oxford Regional Hospital Board for analysis of clinical data, and Mr A Barr for statistical advice.

PARAPLEGIA FOLLOWING SPINAL ANÆSTHESIA

Sir,—In their article (May 12) Dr Payne and Dr Bergentz express doubt on the judge's most carefully considered opinion (in a recent High Court action) that the paralyses which occurred in two consecutive surgical patients resulted from the contamination of ampoules of cinchocaine hydrochloride, injected intrathecally, by the carbolic solution in which they had been stored The cause may have been something else, but (1) I have it on first-hand information that the intrathecal injection of this carbolic solution into higher animals resulted in apparently identical lesions, and (2) I have myself seen that the contents of an ampoule can be contaminated, with a coloured solution in which it is stored, through flaws in the glass too small to be detected by ordinary means

I have just returned from a five weeks' tour of hospitals in West Africa In many the doctor has to tackle practically any situation single-handed, and, if only on this account, spinal anæsthetics flourish My notes show that thousands are given annually, and a striking fact is that in answer to repeated inquiries I did not hear of a single case of resultant paralysis Fortunately the pernicious practice of immersing ampoules of local-anæsthetic solutions in antiseptics is not followed in that part of the world

MEDICAL EVIDENCE

Sir,—I was most interested in your leading article of April 14, and I am sure it must have been welcomed by many practitioners who have appeared in court as expert witnesses and by those whose interest in medicolegal cases is purely academic Few will disagree that the methods of giving medical evidence are unsatisfactory in many respects

The value of a doctor's testimony should depend not on his adroitness as a witness, but on his knowledge and experience as a medical expert Far too often, however, the effect of important medical evidence is lost as a result of the failure of experts to withstand the cunning manœuvres of skilful counsel who are rightly permitted a great deal of licence in court Experts should not be brow-beaten, ridiculed, or disparaged, nor have their sincerity, character, or qualifications assailed with the object of undermining the value of their testimony Surely the object of a court case is to establish the facts, and it is incompatible with justice that established facts should be open to rhetorical distortion

There should be no question of doctors being on one side or the other either in civil actions or in criminal proceedings They should be impartial, and any means of obtaining an objective picture of the medical evidence should be welcomed by all concerned in litigation in which medical evidence features

In order to avoid arguments and discussions on medical evidence in court, in which, after all, lay persons —no matter how brilliant—are scarcely competent to participate, independent experts should be appointed by the Royal colleges to establish the medical facts and state them to the court

Litigants or accused persons should be able to select expert medical witnesses from an approved list to adjudicate on their cases Inevitably they would be confronted by experts selected by the other side The selected experts should, before the case is heard, consider the medical evidence, in the presence of a specially appointed medicolegal chairman, and present to the court their agreed findings as a report At the trial one of the appointed experts would be available to answer questions posed by the judge and or members of the jury in order to leave them in possession of a clear picture of the medical facts

As things are, if the diagnosis of one expert is not agreed by another, surely the only conclusion which the court can reasonably draw is that one of them is not an expert This is a ridiculous situation and brings medical evidence and doctors into disrepute.

London W 1   Ellis Stungo

FATS AND DISEASE

Sir —Dr Sinclair's letter of April 7, with the responses by such figures as Dr Ancel Keys and Professor Yudkin followed by a lecture from the latter, do I think invite a contribution concerning the etceteras that Dr Sinclair may have in mind It may surprise you to receive this from a surgeon

It is hard for a man to give his "vision" words Dr Sinclair has such a difficulty, for a surgeon it is even more apparent Yet there is such a communion with the construction of thoughts, constituting Dr. Sinclair's almost bursting edifice, that from one who is engaged on an etcetera—the formation of gall-stones—words of support must come For the past two years the thoughts have been there. but I have considered it most irregular to put them into words based as they are on meagre experimental and clinical data

The experiments concerning the formation of gall-stones have a centre in the study of the physicochemical properties of bile-salts [1] The characteristics of the molecular arrangement play a significant part in the solubility of cholesterol in the bile, leading to experiments which study the queer and unstable cholesterol/bile salt relationships pH plays a significant part in this. the influence of fatty acids in different forms is about to be studied

This train of thought for future research was accelerated by a visit abroad last year Christensen and Dam in Copenhagen have demonstrated the formation of gall-stones in hamsters [2,3] To me, two things were of special interest Firstly the gall-stone-producing diet is a poor almost starvation, diet Secondly, prevention of gall-stones in hamsters lies in some factors present in certain seeds and nuts which are not subjected to mutilation and possible hydrogenation Brewer's yeast seems particularly efficacious Christensen has noticed the skin conditions that these creatures may also suffer from, and its prevention by these fresh foods He also showed me alteration in the colour and texture of the affected animals' hair, which reminded me of the clinical adage "fair. fat and forty"

Fair, fat, female fecund and forty" is proving to be an uncertain guide, for in surgical practice we are seeing increasing numbers of elderly thin, often male sufferers Perhaps safer anæsthesia has increased the numbers that nowadays come to the surgeon It is plain that thin and fat, old and middle-aged people get gall stones It is difficult to go into the dietary habits and histories of patients with gall-stones, for people cannot remember what they eat However, I have been impressed by a number of patients (well covered) who have disclosed their attempts to diet by periods of near starvation While I was in Scandinavia I found that the same

	1	2	3	4	5	6	
Inpatients	13	28	18	12			71
Outpatients	11	14	26	15	3	1	70

A positive result signifies the finding of the tubercle bacillus by either sputum or bronchial-lavage examination or both Some patients were unable to submit enough sputum for adequate examination, but a satisfactory specimen was always obtained by bronchial lavage The inpatient and outpatient groups were well matched as to bacteriological status at the start of treatment, and the proportions in the two groups showing sputum conversion at three months and at six months were almost exactly the same

TABLE VI—ZONES OF LUNG CLEARED AFTER THREE MONTHS' AND AFTER SIX MONTHS' TREATMENT

Group	After 3 mos		After 6 mos	
	Total patients	Zones cleared	Total patients	Zones cleared
Inpatients	71	20	45	32
Outpatients	70	2[illegible]	46	27

Radiography

The radiographic appearances were assessed by a radiologist who was unaware to which group the patients belonged Table V shows an analysis of both groups o patients according to the number of lung zones involve It will be seen that in many cases the lungs were widel affected and that the outpatients, as a group had mo extensive disease Table VI gives the number of lun zones which cleared in each group of patients after thr months and after six months If anything, more zon had cleared in the outpatients than in the inpatient but the outpatients, as a group, had more zones involve initially

TABLE VII—CAVITY CLOSURE AFTER THREE MONTHS' TREATMENT

Group	Total no of patients	No with cavitation at start	No with cavity closure at 3 mos
Inpatients	71	43	13
Outpatients	70	44	12

Cavitation

In assessing the position as regards cavitation, t cavities were measured at the start and again at thr months and six months Table VII shows the number o patients with measurable cavitation at the start an after three months' treatment, small, multiple cavitie are not included

TABLE VIII—CAVITY CLOSURE AFTER SIX MONTHS' TREATMEN

Group	Total no of patients completing 6 mos treatment	No with cavitation at start	No with cavity closure at 6 mos
Inpatients	45	31	20 (64 5%)
Outpatients	46	33	15 (45 4%)

43 of 71 inpatients and 44 of 70 outpatients had measurable cavities at the start of treatment, and afte three months cavity closure had taken place in 1 inpatients and 12 outpatients

TABLE IX—CLOSURE OF INDIVIDUAL CAVITIES AFTER SIX MONTHS' TREATMENT

Group	Total no of patients	No of cavities at start			No of cavities closed at 6 mos
		Total	<2 cm	> 3 cm	
Inpatients	45	36	17	19	26 (7
Outpatients	46	44	23	21	26 (59

Table VIII shows the number of patients who, having completed six months' treatment, showed cavity closure

At the start 31 of 45 inpatients and 33 of 46 outpatients had cavitation, and after six months' treatment 20 (64 5%) of the inpatients and 15 (45 4%) of the outpatients showed cavity closure

The cavity position in the patients who completed six months' treatment is further analysed in table IX

TABLE X—OVERALL RADIOGRAPHIC ASSESSMENT

Group	Deterioration	No significant change	Improvement			Total patients
			Slight	Moderate	Excellent	
At 3 months						
Inpatients	1	4	8	26	32	71
Outpatients	1	2	11	24	32	70
At 6 months						
Inpatients	2	4	2	18	19	45
Outpatients	2	5	6	10	23	46

This shows that the 45 inpatients had 36 cavities (17 of 2 cm or less in diameter, and 19 greater than 2 cm), whereas the 46 outpatients had 44 cavities (23 of 2 cm or less in diameter and 21 greater than 2 cm) After six months' treatment 26 (72 2%) of the inpatients' cavities had closed, compared with 26 (59%) of the outpatients' cavities

Over all Assessment of Radiographic Changes

The radiographic appearances at three months and at six months were assessed in the categories of (a) deterior

The particular advantage of this method of treatment is its extreme simplicity, which eliminates all the discomforts and inconveniences of starvation and purging necessary when mepacrine or male fern are used, and enables the patient to be treated in his home with little or no interruption of his ordinary activities.

Dichlorophen was supplied by Dr Robert Forgan, of Messrs May & Baker Ltd.

Liverpool School of Tropical Medicine D. R. SEATON

BURNS AND SCALDS

SIR,—The dermatologist, whose opinion is sometimes sought by a surgical colleague, will read with interest and benefit your leader last week.

Most dermatologists, however, would disagree strongly with this recommendation to the family doctor: "Before the development of blisters an anti-histamine ointment may minimise the reaction." It is the experience of many dermatologists that the anti-histamine ointments are rapidly displacing topical sulphonamides and penicillin as the commonest cause of treatment-induced contact dermatitis.

In those cases of burns which can be treated at home, or by a casualty department, a 1% greasy hydrocortisone ointment combined with neomycin is a pain-relieving and safe application. If used early it may prevent blister formation and should guard against secondary infection. It has proved to be a most useful first-aid application in a casualty department where dermatological advice was requested on this problem.

Hove, Sussex PATRICK HALL SMITH

TREATMENT OF TETANUS

SIR,—Professor Lassen and his colleagues are to be commended for their interesting paper (April 28). It is only within recent years that cases of severe tetanus have survived long enough to exhibit bone-marrow depression, which has been reported in a number of recent papers.

There are three factors that are most likely to be responsible: the tetanus toxin, muscle relaxants, and sedatives, including nitrous oxide. In their paper, Lassen et al. present us with some interesting, although inconclusive, evidence that nitrous oxide may be the causal agent.

This problem can be elucidated further only by attempting to separate these three factors. For this reason, I wish to mention a case of a man, aged 49, with infective polyneuritis (shortly to be reported in full).

This patient received intermittent positive pressure respiration for seventeen days until his own respiratory efforts were adequate. Throughout this period narcosis was maintained with nitrous oxide in concentrations varying from 50% to 75%, with oxygen. At no stage did his peripheral blood counts exhibit any signs of bone marrow depression.

I am sure that other workers may have similar cases where neither a toxin nor muscle relaxants need be considered. Such cases should be reported so that the dangers of nitrous oxide can be evaluated.

Meanwhile, I feel that neither the muscle relaxants nor the tetanus toxin itself can be completely absolved as a cause of the bone marrow depression reported in some recent cases of tetanus.

RESIN-REINFORCED PLASTER CASTS

Mr N. P. NEWTON, of Smith & Nephew Ltd., writes:

With reference to the last paragraph of the letter last week from Mr D. F. Thomas, it is not the intention of my company to withdraw from the market 'Gypsona' or 'Glassona.' Gypsona 'Extra' polymer reinforced plaster of paris bandages are complementary to our other splinting materials and not necessarily a replacement.

Personal Papers

TWENTY-THREE YEARS AFTER

IN his essay on child guidance in Old Age,[1] Professor Mackintosh mentioned that in his early 40s he wrote himself a warning letter not to be opened until his 65th birthday. When that day came, he duly unsealed the envelope; and this is what he found:

6th March, 1933.

My dear MACKINTOSH,

I hesitate to call you by your Christian name, because I do not know you well enough. All the same, I think you may profit by a few words of friendly advice. Certain undesirable tendencies in your character and outlook are already apparent; and I have little doubt that they will become more marked as you grow older.

In the first place, you will become more talkative. Do try to curb this fault, because it is the early sign of unwillingness to learn from younger people. It will lead you to a final inability to learn anything. Try to be a good listener as you grow older: it is well worth your pains. But you must *really* listen—not just turn your head and make gestures which have become automatic.

Secondly, do not get suspicious of people and their motives; and avoid especially prying into the affairs of young folk, even on the plea (for self-justification) that you can help them. If they ask for help in time of trial, give it in full measure, but don't imagine that the so-called wisdom acquired by you from experience will help *them*, unless they feel the need. They have to live their own lives. They have *their* souls to keep.

Thirdly, do not try to attract sympathy to yourself. Do not pose as the dear old man, in the hope of hearing affectionate murmurs that you are young in spirit. For God's sake be a real person, with a valuation that does not need artificial boosting. There are three qualities that you can develop as you grow older; they are courtesy, tolerance, and integrity, which together make an understanding spirit. By integrity I simply mean that wholeness of spirit that does not scour a narrow chamber. By tolerance I do not mean an easy-going acceptance of everything that is "done." I mean a mind that is still open; a capacity to understand the point of view of others, and especially of the younger ones; a willingness to argue without acrimony, and yet with fire and spirit. By courtesy I mean the ability to put yourself in the place of other people. It is a rare and beautiful virtue, and it needs to be cherished continually.

The main practical thing to remember, however, is that you are now sixty-five and on the point of retirement. For heaven's sake retire and do not persuade yourself that you are a special case. If you have kept mind and body active, a world of new interests lies before you. If not, then you have no business to cling to office, or indeed to any voluntary or other service to which you are attached. Clear out. Do not rationalise by saying that you "want to see this thing through." That is just another barnacle argument; what you really want to do is to cling.

As we grow older, self-criticism tends to become blunted. I know of no better test than the one proposed by George Meredith:

> "You may estimate your capacity for comic perception by being able to detect the ridicule of them you love, without loving them less; and more by being able to see yourself somewhat ridiculous in dear eyes, and accepting the correction their image of you proposes."

Now remember.

Yours faithfully,
[Sgd] JAMES M. MACKINTOSH.

So he replied briefly to his earlier self:

20th February, 1956.

My dear MACKINTOSH,

Many thanks for your letter of twenty-three years ago. I opened it, as you directed, on my sixty-fifth birthday basal excretion on the previous day and the 0–12 hour excretion on the test day.

---

[1] Lancet, 1947, i, 659.

Patients Studied

The present results were obtained in the first 98 people tested (excluding vitamin-D-resistant osteomalacia)—i.e., 21 patients in whom there was no reason to suspect metabolic bone disease, 12 patients with definite osteomalacia and steatorrhœa, 17 patients with steatorrhœa but no clear evidence of osteomalacia, 18 patients with osteoporosis, and 30 patients with miscellaneous conditions in which bone disease might be suspected. They were aged 14–67 and were either convalescent from an acute illness—e.g., cardiac infarction, peptic ulcer, acute nephritis, colitis, pneumonia, cerebral thrombosis—or had syringomyelia, early rheumatoid arthritis, hypertension, eczema, backache, or very early ankylosing spondylitis.

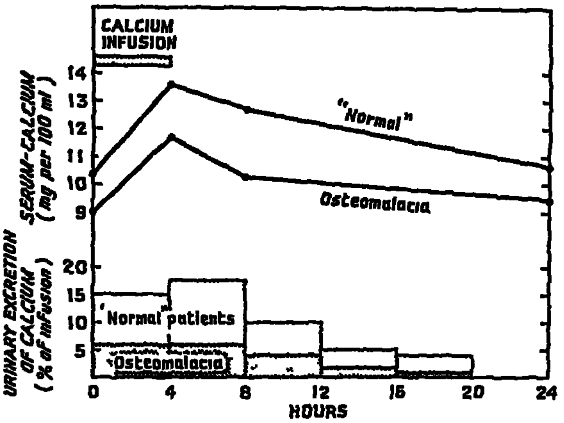

Fig. 1—Changes during test: upper diagram shows mean serum-calcium level during and after calcium infusion in 21 "normal" patients and 12 patients with osteomalacia; lower diagram shows mean urinary excretion of calcium expressed as net percentage of infused calcium (15 mg. per kg. of body-weight).

Patients were classified as having "definite osteomalacia" only if they provided evidence of a cause (all had steatorrhœa and fat absorption less than 90%), presented unequivocal skeletal rarefaction (usually with fractures) on radiography, and had a serum level of calcium × phosphate below 30 mg. per 100 ml. (table I). In almost every case the serum level of alkaline phosphatase was raised, the phosphate/creatinine clearance ratio was high in relation to their serum-phosphate level (Nordin and Fraser 1954, 1956), and biopsy revealed abnormal bone. Clearly some of the patients classed as having "steatorrhœa" may have had milder osteomalacia, but none of them fulfilled all the three criteria laid down above.

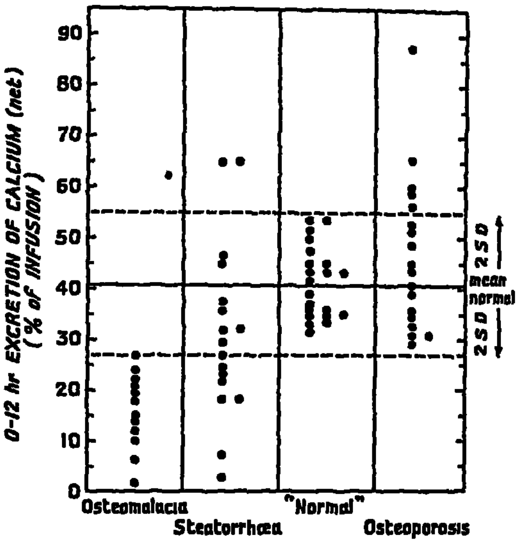

Fig. 2—Individual results obtained after calcium infusion in four main groups of patients.

Normal range, shown between broken lines (27–55%), embraces two standard deviations above and below mean normal excretion of 41% in 12 hr. Note subnormal results in all cases of osteomalacia and 8 of 17 cases of steatorrhœa. See table III for results in miscellaneous cases.

Patients were classified as having osteoporosis if they had definite rarefaction of the vertebral column (usually with "codfish" deformity and crush fractures) without other evident cause—i.e., with normal serum levels of calcium, phosphate, phosphatase, and protein and a normal blood picture.

Results

CHANGES OBSERVED DURING TEST

Fig. 1 shows the mean rise in serum-calcium level and the mean urinary calcium in 21 "normal" patients and

TABLE I—DETAILS OF CASES OF DEFINITE OSTEOMALACIA TESTED

Notes and News

WORLD HEALTH ASSEMBLY

At the ninth World Health Assembly, which opened in Geneva on May 8,[1] the programme and budget committee has approved a budget of $10,700,000 for 1957 [2] The assembly elected the following six member States to serve on the Executive Board of W H O Syria, Mexico, India, Italy, United Kingdom, and Canada The board comprises eighteen members, of whom six retire each year By a vote of 51 in favour and none against, with 5 abstentions, the assembly adopted a resolution designed to facilitate the resumption by inactive members of their rights and obligations in W H O and the settlement of their arrears of contributions Notifications of withdrawal were received in 1949 from the U S S R , the Ukrainian S S R , the Byelorussian S S R , and Bulgaria, and in 1950 from Rumania, Albania, Czechoslovakia, Hungary, and Poland Official contacts between W H O and the U S S R and some of the other inactive members have been re established in the past year. At its meeting last January [3] the Executive Board welcomed U S S R representatives, who explained the position of their government, and expressed its satisfaction at the U S S R 's readiness again to participate actively in the Organisation's work

AN S.H.M O APPOINTMENT

Agreement has not yet been reached in Glasgow over the terms of the appointment of a physician at Bellefield Sanatorium, in Lanarkshire Hitherto the chest services of the area have been provided by consultants centred in Glasgow and by the physician-superintendent at Bellefield who was also a consultant Now that the latter has retired, the Western Regional Hospital Board propose to replace him by a senior hospital medical officer, in the position of superintendent, and to ask one of the Glasgow consultants to act in a supervisory capacity , the vacancy is announced in our advertisement columns this week The regional consultants and specialists committee has not so far been persuaded that the proposed arrangement is justified

NUTRITION RESEARCH AT COONOOR

The annual report for 1954–55 of the Nutrition Laboratories of the Indian Council of Medical Research at Coonoor is a record of steady activities The laboratories now have a research staff of 33, who are clearly maintaining the high standard of work at Coonoor

Studies of vitamins include the development of a fluorometric method for vitamin A assay and an examination of the effect of vitamin D on the metabolism of rachitic epiphyseal cartilages, in which it was shown that vitamin D caused a 100% increase in the citric acid content of the cartilage in twenty four hours Studies on proteins have been concerned with estimations of essential amino acids in common Indian food by microbiological techniques and with the combined effect of calorie and protein deficiencies on the enzyme contents of the organs of rats Human experiments on the maintenance requirements of protein in young Indian adults indicate that these are similar to those of Americans studied by Merlin Detailed quantitative analyses have been made of the octadecanedioic acids present in cow and buffalo fat and in vasaspati Clinical investigations have been carried out on kwashiorkor, with particular relation to the cause of the œdema Field investigations have shown that, whereas the skeletal age of well to do Indian children, determined radiologically, usually compares well with American standards, in half the poor children the appearance of ossification centres of bones of the wrist and hand was delayed by a year or more

THE FARMER AND THE TOWNSMAN

The increasing numbers of town dwellers in every country easily forget how dependent they are on the farmers for their food Farming may seem a dull and unexciting occupation in comparison with much of modern industry with its mechanical marvels , and, as an excellent F A O booklet clearly points out,[4] in every country the average income of the people on the farms is less than that of the people in industry and commerce For these reasons farming is failing to attract the without intervening therapy The results obtained in the two tests agreed closely as follows

*Gross calcium excretion given because basal excretion not measured

Value of Test

It may be suggested that measurement of the 24 hr urinary calcium on a low calcium diet could yield as much information as a calcium infusion We have not found this to be so Fig 3 shows the 24 hr urinary excretion of calcium on the third day of the low-calcium diet for comparison with fig 2 The separation of osteomalacia from the normal state by the calcium infusion was clearly not obtained by measurement of urinary calcium alone, nor did the separation improve when the figures were corrected for body weight It is possible that better separation could be achieved if the diet were continued for a considerably longer period, but the wide range of 24 hr urinary output of calcium on a low-calcium diet in our ' normal " patients (fig 3) is similar to that reported by Albright et al (1929)

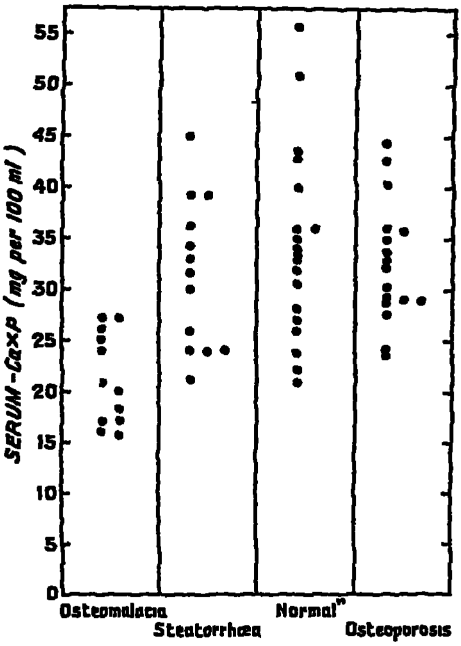

Fig 4—Serum calcium × phosphate levels (same groups as in fig 2)

Note less satisfactory separation of groups by these estimations compared with fig 2

Similarly, we have not found that the serum level of calcium × phosphate is a sufficiently sensitive guide to the state of the skeleton By definition, all our osteomalacia cases had a serum calcium × phosphate level below 30 mg per 100 ml, but fig 4 shows that some " normal ' patients also had a level below 30 mg per 100 ml These values were obtained from samples of blood taken at 10 A M on the day of the test

We do not suggest that this infusion test is infallible in the diagnosis of osteomalacia, nor that it will supplant other forms of investigation, but we believe that in doubtful cases it may provide additional evidence for or against a diagnosis of osteomalacia

Summary

A standard procedure is described for a calcium-infusion test and the results of the first 98 tests are reported

The calcium is administered as the gluconate over four hours in physiological saline solution The dose is 15 mg of calcium per kg of body weight

The net urinary excretion of calcium during the first twelve hours after the start of the infusion was 33–53% in 21 " normal " patients and 2–27% in 12 patients with definite osteomalacia due to steatorrhœa

Of 17 other patients with steatorrhœa 8 yielded results in the osteomalacia range Other evidence suggests that these probably had subclinical osteomalacia

In 18 cases of osteoporosis the excretion was invariably within or above the normal range

30 tests in various other conditions in which bone disease might be suspected yielded low excretion figures in 10 6 of these could be explained by the underlying metabolic disorder, the other 4 remain unexplained

We wish to acknowledge with gratitude the assistance of Dr A Jadresic, Miss Elaine Hunt, Miss Sheila Stewart, and the sisters and nurses of Hammersmith Hospital

POSTGRADUATE MEDICAL SCHOOL OF LONDON

In a previous paper (Nordin and Fraser 1956) we reported the pattern of urinary excretion of calcium after a standard infusion in " normal " patients and in certain types of metabolic bone disease As predicted by earlier workers (Schilling and Laszlo 1951), we found that the urinary excretion of infused calcium was low in osteomalacia due to steatorrhœa, but in only a few cases of osteoporosis was this excretion abnormally high

Since this test therefore failed to differentiate between osteoporotic and ' normal " patients, we decided to elaborate the procedure further We have measured at the end of the infusion not only the net or excess urinary output of calcium, but also the excess calcium still circulating in the extracellular space We considered that this method would enable us to calculate the proportion of the infused calcium deposited in the skeleton—i e, that in neither of these two measured pools (urine and extracellular fluid)—and that this might be low in osteoporosis

We report here the results obtained with this calculation of ' skeletal retention "

Methods

Procedure

The calcium infusion procedure has been described elsewhere (Nordin and Fraser 1956) The estimations required for the ' skeletal retention " data are the basal

CHANGES IN MEDICAL EDUCATION*

JOHN R. ELLIS
M.B.E., M.A., M.D. Camb., F.R.C.P.
ASSISTANT PHYSICIAN TO THE LONDON HOSPITAL; SUB-DEAN OF THE LONDON HOSPITAL MEDICAL COLLEGE

CHANGES in medical education are of two types. Either they are made deliberately to improve it, or they arise incidentally from changes in medicine and its basic sciences or in the conditions of medical practice. Such secondary changes, as we may call them, are frequent and inevitable but not always beneficial. Primary changes are necessary from time to time to incorporate new methods and techniques, but they are even more urgently needed to reorientate the educational processes to new objectives and to repair the damage done by secondary changes.

During the past half century medical teachers and official bodies have made careful and repeated assessments of these changes, and there has been no lack of recommendations on the reform of medical teaching. Some of these have been heeded and put into effect, but in recent years there has been increasing evidence that the process of adaptation has broken down. Whilst most are aware of what is wrong, few are agreed on how to put it right. To quote from a recent report of the Royal College of Physicians: "An American observer lately said that in the past ten years no country has produced so many wise reports on the improvement of medical education as Great Britain, and no country has done so little about it."[1]

My purpose here is to review the changes in medical education—particularly during the past decade—and to consider the further changes now required.

Evolution of British Medical Education

Until about the middle of the past century the training for medicine was entirely by personal apprenticeship. It was in the literal sense a "training," primarily technical and wholly vocational. The method was not appreciably altered even by the grouping of students in hospitals. The relationship of teacher and taught became less close, but the student continued to learn by imitation of his master and by practice for and under him. He continued to learn everything that was practised and very little that was not.

In the second half of the century scientific advance led to a fundamental alteration in medical education by necessitating the inclusion of theoretical study: the scope of medicine enlarged so much that fitness to practise could no longer be achieved by a purely technical and vocational training, but needed also the discipline of the basic sciences. This was a fundamental and primary change, but its implications have never been fully recognised by the profession as a whole. Hence we have been pursuing an educational policy whose very purpose has been neither clear to all nor accepted by all. Because of this basic defect in our educational strategy, there has been no concerted effort on an agreed plan, and such facilities as we possess have not been properly applied.

The 'Block System'

Whatever the reasons (and perhaps the English gift for compromise was not the least of them), we adopted a system of training divided into two parts, one largely theoretical and the other largely practical. This block system, very different from that which emerged on the Continent, continues to this day, the blocks being accurately described as preclinical and clinical. The objective during the preclinical period has been to lay the foundations for clinical practice. But with the progress of medical thought two weaknesses have been exposed. Firstly, the ancillary subjects added to the curriculum fifty years ago no longer provide a complete foundation; and secondly the idea of a foundation has been taken too literally—i.e., as something that is laid down and allowed to dry. A more satisfactory concept would be that of girders which rise vertically through the whole structure.

Fifty years ago the idea of medical education being built up layer by layer was entirely reasonable. Even thirty years ago it seemed adequate, and Flexner, in his comparative study of medical education throughout the world, described it in 1925 as the best that he had seen. But its deficiencies were beginning to be apparent, and he was critical of its application. He thought that the concept of normality gained by the student in the preclinical period suffered from the vocational character of the teaching. (It should be remembered that at this time the link between preclinical and clinical staff was very close: some of the heads of preclinical departments had themselves been engaged in medical practice, and most of the junior preclinical teachers were practising clinicians.) Similarly in clinical medicine he condemned the utilitarian approach. "Listening to a succession of bedside expositions," he wrote, "not infrequently quite chatty in substance and tone, one is struck by the positive note. . . . rarely is the unknown, the problematic, the profounder question, the historic background, attended to."[2] Yet he felt that the British student learned clinical medicine as an intelligent apprentice, one who "in virtue of previous training, is soon capable of orderly procedure in the analysis of symptoms, the arrangement of data, and the drawing of tentative conclusions." He recognised that the supreme strength of British medical education still lay in the careful inculcation of clinical method, and he saw too that this came less from teaching than from constant practise upon patients—freedom to practise clinical method, while having an obvious obligation to the patient as an incentive for doing so. The British student was then "indeed part of the functioning machine."

The Effects of the Growth of Medicine

In the thirty years since that time our educational system has altered very little—but our educational practice has been continuously subjected to *secondary* changes, so that it has altered almost out of recognition. Most of these changes have arisen from the growth of Medicine.

Preclinical teaching.—Scientific advance has added enormously to knowledge: the so-called basic sciences have swollen, reproduced as it were by binary fission, and swollen again. In anatomy a whole new field of living structure has been opened up in twenty years, and the dry bones of topographical anatomy have been agitated by the study of embryology. Physiology has spread so far and wide that it is not clear what is left at the centre. Like biochemistry, and indeed anatomy, it runs from the foundations upwards through the whole medical edifice. These are no longer subjects of which some elementary knowledge is useful for the comprehension of practical techniques—they are processes of thought which are indispensable if the mind is to be brought to bear efficiently upon any medical problem, whether that of an individual patient or of research.

But the student's experience of the preclinical subjects remains cramped between the old limits, not only of time but also of examinations. Confined and isolated between the first and second professional examinations,

(E) *Miscellaneous*

The "4-hr skeletal retention" in this group of patients was 31–59%. Thus none was above the normal range, but the following were below it:

(1) Malnutrition	17%
(2) Acromegaly	16%
(3) Polyostotic fibrous dysplasia	15%
(4) Vertebral compression fractures (unclassified)	41%
(5) Renal calculi	38%

COMPARISON OF "4 HR SKELETAL RETENTION" WITH 0–12 HR URINARY EXCRETION

The relationship between these two types of test result is shown in fig. 2, which shows that in 1 of the "normal" patients the 0–12 hr urinary excretion was less than the lower limit (27%) of the normal range which we have defined in our previous paper; this we cannot explain. The normal range of "4 hr skeletal retention" is slightly narrower than the range of 0–12 hr urinary excretion, and this suggests that the more complicated calculation is more precise.

Fig. 2 also shows that in most of the tests the "4-hr skeletal retention" and the 0–12 hr urinary excretion of calcium together usually accounted for 95% (85–105%) of the infused calcium. Thus, usually, the "4 hr skeletal retention" was about equal to the final total retention of calcium, since later urinary and fæcal losses were small; and so both the "4 hr skeletal retention" and (inversely) the 0–12-hr urinary excretion of calcium usually give a good index of the same function, presumably the final skeletal retention.

While in 11 of the 15 patients with *osteoporosis* the 0–12 hr urinary excretion was normal, in 7 of these 11 the "4 hr skeletal retention" was subnormal. It is these 7 cases in which the urinary excretion data were of no diagnostic value which fact provides the main justification for the rather elaborate procedure described here. 4 osteoporotic patients whose 0–12-hr urinary excretion of calcium was high also had a low "4 hr skeletal retention": 3 of these had Cushing's syndrome and the 4th was a case of post-pregnancy osteoporosis (Nordin and Roper 1955).

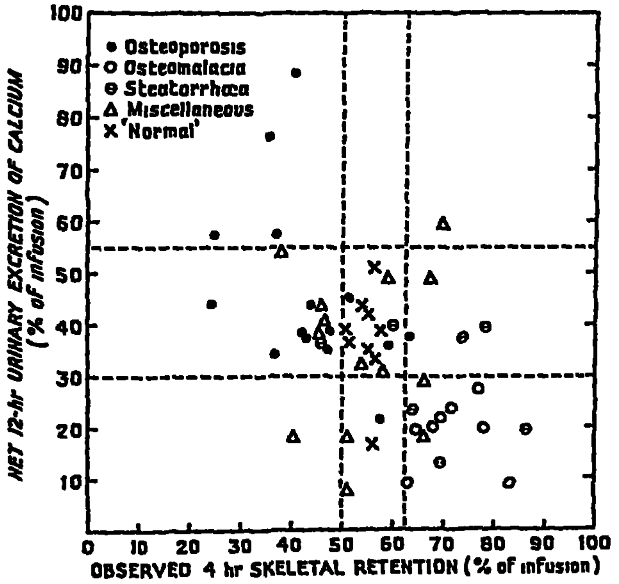

Fig. 2—Correlation between the "4-hr skeletal retention" and 0–12 hr net urinary excretion after calcium infusion.

Note: (1) most results lie within lines enclosing all results where these two figures total 85–105%, so that one figure is usually an inverse reflection of the other; (2) tendency of osteoporotic results to lie towards left of this area (i.e., for 0–12 hr urinary excretion to be more normal than "4 hr skeletal retention"); and (3) while only 4 of 15 osteoporosis cases show excessive urinary excretion, 7 of the other 11 osteoporotics show subnormal "4 hr skeletal retention."

All the patients with osteomalacia were found to have the combination of a high "4 hr skeletal retention" and a low 0–12 hr urinary excretion. 3 patients with steatorrhœa without obvious osteomalacia showed the same combination. 1 patient with steatorrhœa (who had been given intramuscular vitamin D some months previously) showed a combination of low "4 hr skeletal retention" with a normal 0–12 hr urinary excretion, resembling the results seen in osteoporosis.

In only 1 patient (a girl aged 16) with severe hyperthyroidism) was a high urinary excretion of calcium on the test combined with a high "4 hr skeletal retention." The patient with "vertebral compression fractures without evident cause" was unique in that her "4 hr skeletal retention" suggested osteoporosis, while her urinary excretion on the test suggested osteomalacia.

Discussion

We have assumed, for the purposes of the present work, that the infused calcium is ultimately either excreted in the urine or deposited in the skeleton, and that only an insignificant fraction will be lost in the fæces. Previous observations on healthy people (McCance and Widdowson 1939, Baylor et al. 1950) are in accord with these assumptions. Certainly at 4 hours, whatever may happen later, any infused calcium which may have reached the gut will be mostly in the small intestine whose electrolyte contents are normally in equilibrium with the extracellular fluid, and so included in our calculation of the latter's calcium content (Manery 1954).

We have shown that the urinary excretion of infused calcium fell within a fairly narrow range in "normal" patients, and that less was excreted in osteomalacia due to steatorrhœa. In our original series these two groups did not overlap, and we considered that an abnormally low excretion on this test is of diagnostic assistance when this disorder is suspected. The diagnosis of frank osteomalacia, of course, presents no difficulty; but the early diagnosis of incipient cases is impossible at present. Our data suggest that a calcium infusion may serve to distinguish between those cases of steatorrhœa in which osteomalacia is developing and those in which the bones are not so affected. We will be reporting elsewhere in more detail the fact that the urinary excretion in this test is normal in cases of vitamin-D-resistant osteomalacia.

Schilling and Laszlo's (1951) prediction that the excretion of infused calcium would be high in osteoporosis (owing to the failure of the matrix to accept calcium) was not fulfilled (Spencer et al. 1954), and for this there might have been at least two possible explanations: it was quite possible that the osteoporotic skeleton did not differ from the normal skeleton in its ability to accept calcium; but it was also possible that, while the skeleton was rejecting the calcium, the kidneys could not excrete this extra load at a sufficient rate to exceed that of the normals. This suggested that we were perhaps using too large a dose of calcium for our purpose, and that the calcium might be accumulating in the extracellular fluid in the osteoporotic cases. We were reluctant to use a smaller dose of calcium, because of the inevitable increase in the magnitude of the possible error arising from our deriving the excess or net excretion of calcium by deducting the previous day's basal excretion *from* the observed excretion.

Therefore we decided instead to estimate the amounts of calcium circulating in the extracellular space at the end of the infusion, and so to calculate from this and the urinary excretion the proportion of the dose deposited in the skeleton. This calculation showed that in 11 out of the 15 cases of osteoporosis less calcium had been deposited in the skeleton by the end of the infusion than in the "normal" patients. In 7 of these abnormal tests

As so much of the factual knowledge acquired in this manner and for examination purposes is rapidly forgotten, the committee concluded that "while it seems that the educational has been sacrificed to the vocational objective, in fact, neither has been gained." This indeed summarises the situation.

Similar observations were made by a committee of the British Medical Association, and at greater length in the far-reaching study by the Interdepartmental (Goodenough) Committee on Medical Schools. Before considering the changes they proposed and the action that has been taken, it is important to continue the story of changing conditions over the past ten years, for these have had if anything a more serious influence on medical education than all that went before.

The Effects of the National Health Service

The National Health Service has had an entirely unexpected effect on medical education. It is quite clear, both from the special position given to the teaching hospitals and from the Ministry of Health's memorandum in 1950 on the Development of Consultant Services,[4] that the intention was to give high priority to the training of doctors. The boards of governors of teaching hospitals are in fact required to provide special facilities for the clinical instruction of undergraduates, in accordance with the educational policy of the university or medical school concerned.

In the event, however, it has proved financially impossible to implement the plan for establishing consultant centres elsewhere, and the teaching hospitals have become the main regional consultant centres, providing specialist medical care. The effect on the medical schools has varied, being least in the provincial and Scottish teaching hospital groups and in the smaller London hospitals, and greatest in the bigger London hospitals in which specialisation was already advanced in 1948. Everywhere, however, it has become apparent that the educational requirements of the undergraduate teaching hospital are in many ways incompatible with the administrative requirements of a regional consultant centre.

In the first place, the establishment of large diagnostic and therapeutic departments within the teaching hospitals, rather than in associated regional hospitals, has enhanced the distortion of the student's clinical experience, which was already a matter of grave concern. Owing to limitations on new building the expansion of special departments has often been at the expense of general medical and surgical facilities. Segregation of clinical material has increased, and in many fields the clinical experience of the student has lost in breadth and variety, as it has gained in depth and detail. For the special departments have tended to collect rare and difficult cases as well as a disproportionate number of patients attracted by new techniques in surgical treatment. And so the range of cases suitable for undergraduate instruction has progressively contracted.

The changes in teaching-hospital staffs are no less important. Establishment of a special department almost always means the substitution of two specialists for one general physician or surgeon, and there has therefore been a rapid increase in the number of clinical teachers. This access of numerical strength, though obviously of advantage to patients, weakens the cohesion of the teaching team and further reduces the already tenuous contacts between students and staff. For a number of reasons many consultants spend more time at the teaching hospital than before. The development of operative techniques has made the specialist surgeon more dependent on his hospital team, and where private beds are available, private patients have followed the surgeon to the teaching hospital. There is thus a tendency to the geographically full-time status seen in American hospitals. Yet the terms of appointment under the National Health Service have hardly (if at all) allowed the consultant more time or energy for teaching activities, joint consultant rounds, clinical conferences, or tutorial functions. In fact, for most consultants teaching responsibilities are combined with ward rounds or outpatient sessions which are undertaken in contract with the Ministry of Health. Furthermore, the heavy burden of taxation and the shrinkage of private practice have led the young consultant in particular to seek additional sessions at regional hospitals. This has reduced still further his opportunities to meet his colleagues and to take part in those corporate activities of teaching and research which made such a vital contribution to medical education.

These changes have in turn influenced the character of clinical teaching. It is true that some of our wisest teachers have been specialists in some branch of medicine or surgery, and every physician and surgeon must nowadays be a specialist to some extent. A good teacher can teach general principles however narrow his clinical interests. Nevertheless, we cannot ignore the influence of excessive specialisation. Patients are increasingly selected and diagnosis increasingly uses instrumental techniques. The student finds it more and more difficult to gain a sense of proportion. Few clinicians in special departments have a clear conception of the curriculum as a whole, and if they are popular teachers they are all the more likely to contribute to the uneven distribution of emphasis for which the teaching hospitals are justly criticised.

Specialisation also damages the apprenticeship system, because the student is given less and less responsibility. Because of their complexity and importance, operative techniques, postoperative dressings and procedures, and special observation and investigation are carried out by registrars or trained nurses, and the student is reduced to the status of an observer with little sense of participation in the care of the patient or the activities of the medical team. Students tend to become passive listeners instead of active learners and to lose the habit of critical discussion and inquiry.

Many will think that this is an exaggerated picture or that these conditions apply in only a few badly regulated medical schools. I am well aware of the great differences in development and organisation of different teaching hospitals, in both London and the provinces, and I agree that what I have described is not a generally established state of affairs. But the trend is universal, and it has been much accelerated by the development of the National Health Service. The requirements of medical education demand that the teaching hospitals should remain in the forefront of medical progress. To do this they must encourage specialisation and provide the facilities for clinical and laboratory research. But a *balance* must be maintained. Some more authoritative organisation than exists at present must be given the responsibility for preventing or correcting the undesirable side effects on medical education which I have outlined.

Changes in Premedical Education

In the past ten years the field from which medical students have been selected has been considerably widened. Payment of fees and maintenance grants by education authorities has greatly reduced the hardships or stringencies previously imposed by finance. It is probable that these restrictions now operate, if at all, only on the children of those in higher income groups who may be ineligible for the payment of awards they have won. Although it is now easier for many parents, it is harder for those in the professional classes to send their sons or daughters into medicine.

An excess of applicants over places in medical schools has made selection possible. It is, however, very hard

---

ROSEOLA INFANTUM

AN ISOLATED OUTBREAK

N. D. REIS

M.B. Lond.

CAPTAIN, R.A.M.C.

A SMALL outbreak of roseola infantum in April and May, 1955, was confined to a single block of married quarters in Kensington Village, then the largest British Army families' cantonment in Fayid, Suez Canal Zone.

Epidemiology

The block of quarters involved in this isolated outbreak consisted of eight rooms forming a long bungalow. A separate stone-built ablutions block stood at the back of the main building, each family having its own bathroom and bucket latrine. The children associated with one another daily. This block was surrounded by other similar blocks at distances of 20–100 yards. Meals were eaten communally in a dining hall. The accompanying table shows the cases.

There was no case outside this block. The source of infection was not found. The only unaffected child living in this block was the eldest (9½ yr.) of three in rooms 6, 7, and 8. Five girls and two boys were affected. No adults were affected. Only one child (case 3) was of school age; he remained at school throughout, not having reported sick. In each family the younger child was affected first, suggesting that incubation may be lengthened by age. Cases 6 and 7 arrived in Fayid from the U.K. on May 1, 1955; they were the last two cases, and pyrexia developed on May 5 and May 8 respectively, a fact which sets a maximum of 4 and 7 days on their respective incubation periods. An incubation period of 2–5 days seems probable for this series as a whole.

Other infectious fevers in the village at the time were measles, scarlet fever, and chickenpox.

Clinical Manifestation

The clinical manifestations were very similar in all the cases. The onset took place with mild pyrexia lasting 2½–3 days, with temperatures of 101–102°F on the first 2 days and 99–100.6°F on the last day. At this stage no further clinical signs were noted except in case 4, who had nasal catarrh and mild conjunctival injection. None had noticeable faucial, palatal, or pharyngeal injection. The children were listless and fretful. On the 3rd day the pyrexia suddenly collapsed after the appearance of the rash. The exanthem was of rose maculopapules 2–10 mm. in diameter. The rash, always discrete and nowhere confluent, began on the face and spread rapidly to the upper limbs and neck and reached the back and abdomen in a few hours. Its maximal spread and intensity were reached within 24 hours. The final distribution was centripetal, the macules becoming very scanty towards the extremities and the hands and feet being free. The greatest concentration of macules was on the face, upper arms, and back. Within a few hours of the appearance of the rash the children all felt perfectly well again, and confinement to bed and house became difficult. Many of the maculopapules were surrounded by a striking zone of pallor giving them the appearance of being encircled by a white ring. This appearance is stated to be pathognomonic of roseola infantum (Zahorsky 1947). The rash faded away slowly in 3 or 4 days, leaving no stain or scaliness of the skin.

DATA ON CASES

Case no.	Room nos.	Age (yr.)	Sex	Date of rash
1	1 and 2	3	F	April 29, 1955
2	5	2	F	May 1
3	1 and 2	5	M	2
4	6, 7, and 8	1¾	M	4
5	6, 7, and 8	2¾	F	6
6	3 and 4	2¾	F	7
7	3 and 4	1	F	11

Discussion

The clinical picture and incubation period are those of roseola infantum, but enlargement of occipital lymph glands, catarrhal tympanitis, and palatal injection described by Clemens (1945), Windorfer (1954), and McQuitty (1955), were absent.

After seeing these few cases I am convinced that this infectious fever is a separate entity—a claim which is often denied. Some workers claim that it is atypical rubella. In this series too it was considered whether a common rubella contact could have caused the outbreak with small variations in the incubation periods; but cases 6 and 7, which were typical, prove that the incubation period of this group was far too short for rubella. The β-hæmolytic streptococcus is also sometimes cited as the cause, but clinically roseola infantum has no resemblance to scarlet fever.

The isolation of this outbreak in a single block is curious and unexplained. Among the young children of the block it was highly infectious; yet it did not spread through the school from case 3 or through the communal dining-hall from any of the cases during the incubation period. This suggests that droplet case-to-case spread is unlikely. Spread through intimate contact alone was a possible explanation. The isolation of the outbreak to the one block led to a search for a common source of infection there. Food or water borne infection was unlikely but could not be entirely excluded. Feeding was communal, and the water-supply came from the same mains as that of surrounding blocks. In these circumstances one would have expected other cases to arise. The block cleaner or one of the adults on the block may have been a carrier or, more likely, the bearer of fomites. The animals in this block consisted of some resident cats and several stray dogs, which spent most of the day there. These again were possible carriers. An alternative to the suggested case-to-case spread by intimate contact is therefore a common undiscovered source in the block.

Summary

A curious and isolated outbreak of 7 cases of roseola infantum is described.

Maximal incubation periods of 4 days and 7 days were found in two cases.

Certain commonly observed signs were absent and no complications were noted.

Roseola infantum is a striking separate entity.

I wish to thank Dr. J. Fleming, late captain R.A.M.C., my colleague at the time, Dr. H. W. S. Francis, late captain R.A.M.C., for suggesting the diagnosis; and Major-General F. J. O'Meara, Colonel M. J. H. Kelleher, and Colonel F. P. H. Lassen for encouragement and invaluable help.

understand, but yet bearing an unpleasant similarity to those preclinical subjects which he found hard and dry.

So he spends little time methodically obtaining a basis of pathology, and in fact he learns very little for himself. Never having done so before, he hardly knows how to begin; and in any event he finds that he is given a large amount of teaching. Unfortunately the teachers, unlike those he has previously experienced, seem to teach at random—their subjects being in fact dependent on the ever-changing nature of the patients under their care—and, what is worse, teachers now conflict with each other. Medicine seems to be most confusing, and it would be pleasant indeed to escape by busying himself in doing something (however small) for the patients themselves.

Unhappily there is little he can do, and although he must learn about clinical investigations in the abstract he is but rarely considered competent to collect the specimens on which the tests are made, let alone make the tests. Thus he finds himself with almost no apparent responsibility to the patients still described as his; and, relegated to the rôle of observer, he wanders rather disconsolately from department to department, trying to remember as much as possible of the specialised knowledge poured out to him in each by his many teachers. And perhaps he takes the opportunity to see something of life, which he has been too busy to do since he was 16. Now at 21 he plays games again and does those things which many of his non-medical friends have already got tired of doing. Thus he continues, losing heart in medicine from which he drifts further away. A course of pathology may help, and then midwifery brings a most welcome change. At last he seems to be a part of the medical profession—at last he has something to do. He enjoys midwifery. Then quite suddenly he finds that his final examinations are now within measurable distance. His existence is threatened. His financial support may cease if his examinations are not passed. He remembers the very many learned discourses which have gone over his head since he began his clinical studies. Somehow he must now master this vast mass of knowledge, for that surely is medicine.

Appalled at his believed ignorance, and at the size of the task ahead, he cuts himself off from normal life, eschews all that remains of his curriculum which is not obviously or by repute directed towards the passing of his examinations, and struggles to learn what he now thinks is medicine—from books, and from those very "factual" teachers who are happy to give him lists of causes, lists of symptoms and signs, and descriptions of treatments which can be quickly memorised. Somehow or other he manages to pass, sooner or later, an examination which is primarily a test of knowledge but almost never a test of training.

Through this standardised curriculum the student often passes without guidance—one of a group, unknown as an individual. He is subjected to "group" training throughout, and his experience and learning are both affected by the "personality" that his particular group takes on. There are mature and immature, active and passive, interested and uninterested groups.

Fewer and fewer opportunities exist for him to choose some aspect of medicine for more particular study or to carry out some elementary scientific inquiry. As in a factory, he is placed on a belt, and this inexorably carries him through three years of production. He is mass produced, and the end-product is neither the practical doctor, capable of dealing with common problems, nor the young man who has learnt how to learn and has become capable of applying clear thought to clinical findings. Too often it is a somewhat immature young man, with a considerable knowledge of uncoordinated details and a weak understanding of principles; with an insecure foundation in clinical method and small ability for scientific appraisal; ill-prepared for the responsibilities to come, of which he has been made little aware.

This factory differs fundamentally from others in that at each stage of the process, in each department, what is done to the product matters much less than what the product does. Teaching is far less important than learning.

The dean's office keeps the production line moving; the teachers teach (year in year out, without pause for respite, reflection, or assessment of results); but the incentive to learning comes mainly from fear of examinations, and the learning is directed to the accumulation of factual data with which to pass them. This fear is greater than it has ever been before, and so is the body of factual knowledge.

Again, many may think that I have exaggerated. Obviously the picture varies from school to school, but I submit that the trend is in the same direction everywhere—and the direction leads away from the patient. It is only too easy to be unaware of this; for as teachers our period of observation of the individual student is limited, and it gets smaller as the number of teachers increases. Our assessment of the results of education is made, for the most part, on house officers usually selected because they were regarded as the best students. Moreover, it is made during a period of rapid maturation, when enthusiasm is replacing boredom, and the mental infarction of five years is being recanalised.

Attempts at Reform

Having reviewed the major environmental changes which in recent years have reacted, usually unfavourably, on the practice of medical teaching, I turn now to the remedial aspects. What has been done to correct these secondary deviations? Many excellent recommendations were made in the various reports. The most far reaching were those of the 1944 committee of the Royal College of Physicians and of the Goodenough Committee, and some of these found expression in the Recommendations of the General Medical Council in 1947 and in the Medical Act of 1950 on preliminary-registration house-appointments. The General Medical Council was mainly concerned with correcting a number of deficiencies in the clinical curriculum. Thus it recommended that certain special subjects such as social medicine, pædiatrics, and psychological medicine should be given greater emphasis and teaching time. But it was also concerned at the intellectual gap between preclinical and clinical studies and recommended the addition of a three month introductory course transitional between these two phases of training. The majority of medical schools have tried to fulfil most of these demands, and the increase in number and strength of the whole time clinical units, advocated in the college report, has been an undoubted factor in doing so.

The introductory course has, I believe, done much to secure smoother transition between the systematic disciplines of anatomy and physiology and the unsystematic teaching of clinical medicine. It has been the more effective where preclinical and clinical teachers have previously joined forces in clinical demonstrations to illustrate the applications of anatomy and physiology. Nor can one be critical of the greater emphasis which has been placed on social and psychological medicine, for the doctor is increasingly faced with practical problems in these fields. Yet the regrettable outcome of these changes has undoubtedly been to increase the already unreasonable load of instruction with which the student is faced during his clinical years. What is more, the burden has in some schools been increased by special examinations in pædiatrics and psychological medicine.

pressin Other experiments (Falbriard et al 1955) indicated that the secretion of aldosterone was possibly stimulated by corticotrophin

Conclusion

Our experiment demonstrates a homœostatic mechanism affecting the secretion of aldosterone as a consequence of changes in the volume of body fluid This regulation seems to be independent of the pituitary adrenal system Liddle et al (1955) note a diminution of the sodium-retaining factor in the urine of dogs and man after the administration of vasopressin, and they suspect that it is not the serum sodium level but the volume of the body-fluid that influences the secretion of aldosterone Apart from this homœostatic regulation of the production of aldosterone by some volume of body fluid, the production of aldosterone probably also depends on corticotrophin Studies are now in process to establish which fluid compartment may be involved in this homœostatic regulation of aldosterone

Summary

Evidence is presented that the urinary excretion of aldosterone is controlled by some volume of the body fluid

This homœostatic regulation of the secretion of aldosterone is independent of the secretion of corticotrophin, but corticotrophin nevertheless can also influence the secretion of aldosterone independently

INGUINAL ENDOMETRIOSIS

Thomas L Dormandy
M B Lond, B es Sc Geneva
LIEUTENANT R A M C, LATE SURGICAL REGISTRAR
HACKNEY HOSPITAL, LONDON

In 3 patients seen within five months in the surgical outpatient department of the Hackney General Hospital a fairly confident clinical diagnosis of inguinal endometriosis was confirmed

This rare condition was first reported by Cullen in 1896 Thirty years later Polster, in a collective review of over 1000 cases of endometriosis, found 34 inguinal lesions, including intraperitoneal and the apparently less common extraperitoneal deposits

There was no inguinal localisation in a number of later series (Pumphrey 1937, Moss 1939 Dreyfuss 1940 Colcock and Lamphier 1950), but a very unusual case was included in Sanders's survey (1943) a patient who bled from a sinus opening in the groin during her periods Masson (1945) reviewing 2686 recorded cases of endometriosis affecting 4307 sites found no example of inguinal endometrioma though he noted 2 cases with deposits in femoral hernial sacs Fallon et al (1950) found 1 in 400 cases of external endometriosis and Scott and Te Linde (1950) 1 in 514 cases

In 1954 Daro et al wrote

> In a survey of the 3250 cases of external endometriosis reported during the past 17 years there were only 26 (0 8%) in which the condition was localised in the round ligament and only 13 (0 4%) in which it was definitely demonstrated to be in the extraperitoneal part

This bears out Counsellor's statement (1948) that contrary to what the close anatomical relationship between pelvic organs and inguinal canal would lead one to expect, the latter is one of the rarest sites of endometriosis

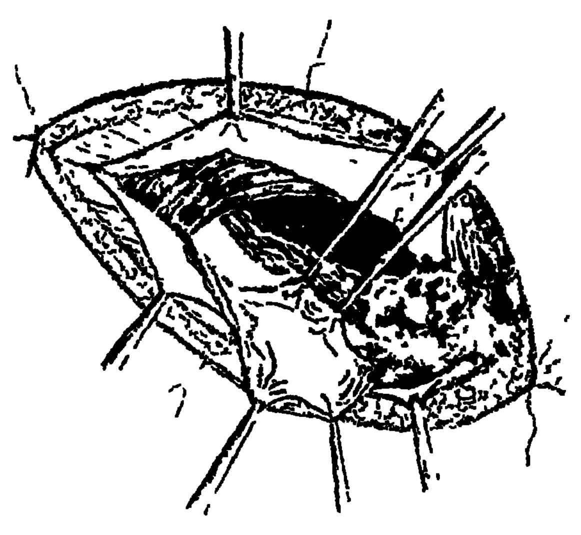

Fig 1—Operative exposure of the inguinal endometrioma in case 1 The canal of Nück has been opened

Among individual cases described in clinical detail are those of Cullen (1920) Sampson (1925) Dickinson (1939) Lyall (1943) Mazza (1949), Rubinstein and Kurzon (1952), Daro et al (1954), and Labry and de Mourgues (1954)

Case-reports

THE FIRST CASE

Mrs A, aged 38 was referred to the outpatient department with "recurrent inguinal lymphadenitis" She gave a fifteen years' history of a painful lump in her right groin which regularly increased in size two or three days before her period At the same time the pain and tenderness became more intense She had already had two courses of injections—one from her own doctor, and one in the casualty department at another hospital—but neither had benefited her more than temporarily

During her most recent menstrual period the pain in her groin had kept her confined to bed for seven days and had reduced her to exhaustion

Apart from the inguinal pain she had never suffered from any form of menstrual discomfort, intermenstrual bleeding, vaginal discharge, backache, or dyspareunia During the past ten months she had noticed a lengthening of the intermenstrual period and a diminishing loss Her general health was excellent

She had one son, aged 17, whose delivery had been normal Three years after his birth she was operated on for a right tubal pregnancy Three years after this she had a miscarriage

Examination

A lower right paramedian abdominal incision was soundly healed and not tender There was moderate tenderness and diffuse induration over the right external inguinal ring but no redness, subcutaneous œdema, or enlarged lymph nodes A faint but definite cough impulse was present in both groins Rectal and vaginal examination were negative The diagnosis of endometriosis of the canal of Nück was made

Operation

Through an inguinal skin-crease incision a grey mass of fibrous consistence the size of a cherry was displayed It overlapped the external ring and was densely adherent to the external oblique aponeurosis the emerging round ligament and the fat of the abdominal fascia The inguinal canal contained an empty indirect hernial sac which reached the fibrous mass and was inseparable from it On opening the sac the glistening peritoneal surface appeared intact (fig 1) The sac was divided and its proximal end closed In separating and removing the distal part together with the fibrous nodule and round ligament small cysts were entered and dark fluid escaped The internal ring was obliterated the inguinal canal reinforced with floss nylon darn the external oblique aponeurosis sutured and the skin closed with drainage

Follow up

The patient made an uneventful recovery Since her discharge she has had several menstrual periods without recurrence of symptoms

TABLE I—SEX DISTRIBUTION AMONG GENERAL POPULATION

Age (yr)	No of men in group	Preponderance of women in general population	Expected no of women
45–49	34	0	34
50–59	95	10%	104
60–69	78	31%	102
70 or more	44	49%	66
Total	251		306

the effect of parity and of weight on the incidence of diabetes The study comprised 1134 patients, of whom 181 were excluded because of inadequate data regarding height or weight at the time of diagnosis Many of the excluded patients had originally attended other clinics, and it was impossible to obtain the necessary information about them Of the remaining 953 patients 583 were women and 370 were men Their ages at diagnosis are shown in fig 1 A preponderance of women is seen among those in whom diabetes is diagnosed in middle and late life

TABLE II—PARITY OF NORMAL WOMEN (MARRIED AND UNMARRIED) AGED 45–49 (1% SAMPLE OF 1951 CENSUS)

Parity	Percentage	Parity	Percentage
0	32 6	4	5 9
1	21 8	5	3 0
2	20 6	6	2 0
3	11 2	7 or more	2 9

If a division is made at the age of 45, there are 106 women and 119 men under this age but 477 women and 251 men over this age An attempt has been made to account for the preponderance of women among the older patients

Sex-distribution among the General Population

Part of the difference is due to the fact that there are more middle aged and elderly women than men in the general population In the age-group 40–49 the sexes are equally numerous, in that of 50–59 there are 10% more women, in that of 60–69 31% more women, and over the age of 70 there are 49% more women These figures indicate that some excess of women would be expected apart from any factor operating selectively (table I) Part of the sex difference in older diabetics is due to the excess of women in the general population at this age

TABLE III—EXPECTED NUMBER OF WOMEN IN EACH PARITY GROUP

Parity	No of women expected	Parity	No of women expected
0	100	4	18
1	67	5	9
2	63	6	6
3	34	7 or more	9
		Total	306

Parity

Figures for the parity of normal women aged 45–49 in England and Wales may be obtained from the 1% sample of the 1951 Census * and are shown in table II

If the 306 women, who would be expected to correspond to the 251 men aged more than 45 among the present group of diabetics, are divided in these proportions, the figures shown in table III are obtained

The numbers in each parity group among the diabetic women are given in table IV

If the observed figures are compared with those theoretically expected (table V), it is found that the excess of diabetic women is confined to those who have borne children, the number of nulliparæ (91) being about that expected (100) The relative excess of women increases with each degree of parity A woman with five children has about three times as much chance of developing diabetes as a woman with none This is represented in fig 2

TABLE IV—PARITY OF 477 WOMEN IN WHOM DIABETES WAS DIAGNOSED OVER THE AGE OF 45 (ONLY LIVE BIRTHS ARE INCLUDED)

Parity	No of women	Percentage
0	91	19 6
1	69	15
2	89	19 3
3	58	12 5
4	44	9 5
5	27	5 8
6	25	5 4
7 or more	60	12 9
Not recorded	14	
Total	477	

It thus appears that parity and the normal difference in sex-distribution among the general population together account for all the excess of women observed in diabetics

TABLE V—COMPARISON OF OBSERVED AND EXPECTED NUMBER OF WOMEN IN EACH PARITY GROUP

Parity	Theoretical no expected	Observed number	Observed/ expected (%)
0	100	91	91
1	67	69	103
2	63	89	141*
3	34	58	171†
4	18	44	244†
5	9	27	300†
6	6	25	417†
7 or more	9	60	667†
Total	306	463	

*P (χ^2) < 0 01 n = 1 †P (χ^2) < 0 001 n = 1

Parity and Age at Diagnosis

Parity does not lead to the appearance of diabetes earlier in life Table VI shows the average age at diagnosis for women aged more than 45 The age at diagnosis is similar for all degrees of parity

TABLE VI—AGE AT DIAGNOSIS OF WOMEN OVER 45 IN RELATION TO PARITY

Parity	No of women	Average age at diagnosis (yr)
0	91	60 4
1	69	59 0
2	89	60 4
3	58	60 6
4	44	60 7
5	27	59 0
6	25	63 7
7 or more	60	63 3

Weight

That the effect of parity on the incidence of diabetes is not merely a reflection of a greater incidence of obesity among multiparæ is suggested by table VII, which shows that about 31% of the nulliparæ are overweight † inch and a half in diameter, spreading over the insertions of the inguinal ligament, the conjoint tendon, and the anterior rectus sheath and densely adherent to the subfascial fat and pubic periosteum. It was of an almost cartilaginous consistence but enclosed three cystic areas which contained pale green fluid; it was associated with an empty indirect hernial sac and a dilated and tortuous pampiniform plexus.

---

* Figures are not given for the parity of women aged more than 49 It must therefore be assumed that the parity of women aged more than 49 in 1951 was not significantly different from that of those then aged 45–49

† Overweight is here defined as 10% or more above, and underweight as 10% or more below, the average weight for height and age given by the Association of Life Insurance Directors and Actuarial Society of America in 1912 and cited by Duncan (1952)

The mass, the round ligament, the plexus, and the fundus of the sac were excised, and the posterior wall of the inguinal canal was repaired.

Histological Examination

Endometriosis was seen in an atrophic phase (fig. 3): the glandular clefts were in part denuded of their lining layer; scanty muscle tissue was interspersed with hyalinised patches of fibrosis; and there was but one central area, surrounding a small blood-filled space, which contained macrophages in any number.

Follow-up

Since her operation the patient had two menstrual periods without discomfort. She is completely relieved of her nagging pain.

Discussion

Though endometriosis is increasingly diagnosed in gynæcological departments I could find no mention of the inguinal variety in six standard general surgical textbooks (four British and two American) and two books on diagnosis.

Diagnosis

Despite the characteristic history a preoperative diagnosis is but rarely made.

Hernia.—Hernia was diagnosed in the majority of reported cases.

The patient of Daro et al. (1954) was not only forewarned of impending menstruation by the appearance of the inguinal pain, but she could foretell whether the loss would be slight or heavy by its intensity. Despite this history, and the swelling which appeared with the onset of the period, the condition was thought to be a strangulated omentocele. "As a general rule," reflects Daro, "the symptoms of inguinal endometriosis are rather uniform. . . . However, this condition is so rare that endometriosis is seldom considered as the exciting factor in the train of events."

In Labry and de Mourgues's patient (1954) the "hernia" appeared suddenly after unaccustomed exercise. It was at first easily reducible and freely transmitted the cough impulse.

In all our three patients a patent canal of Nück was present and in two a cough impulse could be elicited. It is also possible, if the endometrioma is small and mobile, to perform a *reduction en masse* into the inguinal canal. Not only may this lead to the wrong preoperative diagnosis, but even at operation the familiar sight of a peritoneal sac may divert attention from a comparatively inconspicuous endometrial nodule.

Inguinal Lymphadenitis.—Novak (1947) pointed out the pitfall of enlarged inguinal lymph-nodes. As the painful endometrial swelling tends to disappear at the end of each period, spurious cure follows any treatment; and when an antibiotic has been used, this is regarded as proof of its infective origin. Only the first of our patients mentioned spontaneously that her attacks coincided with her periods; the other two had not connected the two events in their own mind.

Unlike inguinal lymphadenitis with its multiple nodules, inguinal endometrioma usually presents as a solitary lump, or, in the quiescent state, as diffuse induration rather than as a well-defined mass.

Varicocele of the round ligament.—I recently operated on a patient who gave a history of a painful lump in the groin which had appeared three times with the approach of menstrual periods and had disappeared each time shortly after the bleeding had stopped. In the groin she had an ill-defined, partially reducible, tender swelling which transmitted the cough impulse. Exploration for yet another case of endometriosis revealed a tortuous and partially thrombosed pampiniform plexus.

Though uncommonly diagnosed, this condition is not rare, and it shares with endometrioma a periodicity of symptoms which is governed by the menstrual cycle. Varicoceles may become painful and prominent in the premenstrual phase, as they do during the first few months of pregnancy; and thrombosis in the dilated veins results in a firm, tender, irreducible swelling (Tomkinson and Winterton 1955).

Pathology

Three forms of inguinal endometriosis have been described.

1. Sampson (1927) in a classical paper advanced endometriosis of hernial sacs as one of his arguments in favour of his "spill" hypothesis. This intraperitoneal variety—which includes endometriomata arising from cysts of the canal of Nuck—could also be derived from endometrial islands in the peritoneal serosa (Ivanoff 1898, Meyer and Kitai 1924).

2. Less commonly, endometriomata are found extraperitoneally. In our 3 cases, though hernial sacs were present, careful naked-eye and microscopic examination revealed no continuity between the intact peritoneum and the endometrioma. For this group "endometriosis of the round ligament" is a description *faute de mieux*: in our sections this structure was clearly defined, but in none did it contain ectopic uterine tissue.

3. Endometriomata may also appear in the form of lymph-node deposits, supporting in MacLeod's view (1950) the hypothesis of lymphatic spread. Such deposits can be histologically distinguished from the foregoing types by the absence of all muscle tissue.

In our 3 cases one could judge from the microscopic section the approximate phase of the menstrual cycle at which the operation was performed. The inguinal endometrioma removed from a pregnant patient by Rubinstein and Kurzon (1952) showed advanced decidual change.

In these 3 patients—as in 9 out of 12 cases individually reported in the literature—the endometrioma was on the right side.

Treatment

All symptoms were relieved by excision of the endometrioma in our patients, and in view of their age recurrence is unlikely.

Summary

3 patients with inguinal endometriosis were seen within five months in a surgical outpatient department. All 3 complained of a painful lump in the groin which recurred with each menstrual period.

Unless this history is elicited there may be difficulty in distinguishing this condition from hernia, enlarged inguinal lymph-nodes, or a thrombosed varicocele. Any of these may coexist, and distract attention from the endometrioma at operation.

The literature of inguinal endometriosis is reviewed and three pathological types are recognised: an intraperitoneal and an extraperitoneal variety, and the purely endometrial lymph-node deposit.

Like congenital hernias and undescended testicles the condition appears to be commoner on the right side than on the left.

Treatment by excision brought complete relief in all cases.

I should like to thank Mr. J. R. Stead for permission to publish these cases, for guidance and encouragement, and Miss Gladys H. Dodds for helpful criticism and advice.

BED REST IN THE TREATMENT OF PULMONARY TUBERCULOSIS

W F TYRRELL
B Sc, M B Glasg, D P H
CHEST PHYSICIAN, RUCHILL HOSPITAL, GLASGOW

IN 1926 Stocks and Karn claimed to show statistically that patients with pulmonary tuberculosis who were treated in sanatoria fared no better than those who were not, and the controversy arising from this work has continued spasmodically with no clear cut result Most workers in pulmonary tuberculosis know of patients who have overcome their disease without entering a sanatorium This raises the question whether their disease would have been more quickly or more certainly arrested if they had followed the conventional path In other words Is rest in bed really necessary for most patients with pulmonary tuberculosis ? I describe here the preliminary results of an attempt to answer this question

Material and Method

In May, 1954, it was possible to admit to sanatoria only some of the patients with pulmonary tuberculosis in Glasgow, and the remainder were of necessity treated as outpatients From a public health viewpoint this situation was clearly unfortunate, but it did offer an opportunity of assessing the therapeutic value of bed rest It was accordingly decided to admit to hospital every alternate new patient in the Northern area of the city and to treat the others as ambulant outpatients The criteria for acceptance into the trial were that the patient (1) had active pulmonary tuberculosis, (2) was aged 14–54, (3) was not living in lodgings, and (4) was ambulant when first seen Those allocated to inpatient treatment were admitted to the sanatorium within two weeks of diagnosis and were kept on strict rest in bed

TABLE I—AGE DISTRIBUTION OF INPATIENTS AND OUTPATIENTS, BY SEX

Group	Age (yr)				Av age (yr)
	14–24	25–34	35–44	45–54	
Males					
Inpatients	14	11	5	4	29 5
Outpatients	12	11	7	3	30
Females					
Inpatients	24	8	4	2	24 6
Outpatients	17	13	7	1	27 5

The outpatients in the trial were encouraged to remain up and about, and all except 5, who were treated similarly by their own doctors, reported to the hospital for injections of streptomycin Apart from the amount of exercise allowed, the inpatient and outpatient groups had identical investigation and treatment

Altogether 141 patients have completed three months' treatment, and 94 of these have completed six months' treatment In these 94 cases the chemotherapy consisted of streptomycin 1 g and isoniazid 400 mg on the same day twice weekly, and the remaining 47 patients, who have so far completed only three months' treatment, received the same chemotherapy on five days each week 1 male outpatient and 1 male inpatient had to be withdrawn from the trial before three months' treatment was completed because of drug sensitivity and tuberculous empyema respectively, 3 females in the six-month treatment group left hospital between the three and six month periods

Table I shows that the inpatient and the outpatient groups were closely matched in age distribution

Results

Erythrocyte sedimentation Rate

Table II shows the number of patients in each group who had an erythrocyte-sedimentation rate (E S R) greater than 10 mm in the first hour (Westergren) at the three periods of assessment

TABLE II—E S R LEVELS

Group	No completed 3 months' treatment			No completed 6 months treatment		
	Total	E S R >10 mm		Total	E S R >10 mm	
		At start	At 3 mos		At start	At 6 mos
Males						
Inpatients	34	23	10	23	17	3
Outpatients	33	27	8	22	20	4
Females						
Inpatients	37	27	15 −2 preg	22	15	6 −1 preg
Outpatients	37	28	14	24	21	8 −2 preg

Of the 25 female inpatients in the six month treatment group (including 1 who was pregnant), 3 left hospital irregularly between three and six months, so the numbers of patients who actually completed six months' treatment in the various groups are

Males inpatients 23 outpatients 22
Females inpatients 22 outpatients 24

Table II shows that 2 of the inpatients at the three-month stage and 1 at the six month stage were pregnant, and 2 of the outpatients were pregnant at the six-month stage All 5 had an E S R greater than 10 mm, but are not included in the main figures as their pregnancies may have been the cause of the raised E S R Table II shows no significant difference between the groups in regard to E S R response to treatment That the two groups were well matched in initial severity of illness is also shown by the fact that 35 of the inpatients and 31 of the outpatients had an E S R of 30 mm or more at the outset

Body weight

At the start of treatment, both the male and female inpatients were on the average slightly lighter than the outpatients (table III) At three months the male inpatients and outpatients had gained approximately the same weight, whereas the female inpatients showed an appreciably greater gain than the female outpatients At six months both male and female inpatients had gained a further appreciable amount of weight, whereas on the average the male and female outpatients had lost

TABLE III—AVERAGE BODY-WEIGHTS

Group	Average weight (lb) at start	Average gain (lb)	
		At 3 mos	At 6 mos
Males			
Inpatients	127	9	15 5
Outpatients	132 5	8	5 9
Females			
Inpatients	109 2	14 5	21 1
Outpatients	113 4	6 6	5 2

inch and a half in diameter, spreading over the insertions of the inguinal ligament, the conjoint tendon, and the anterior rectus sheath and densely adherent to the subfascial fat and pubic periosteum. It was of an almost cartilaginous consistence but enclosed three cystic areas which contained pale green fluid; it was associated with an empty indirect hernial sac and a dilated and tortuous pampiniform plexus.

The mass, the round ligament, the plexus, and the fundus of the sac were excised and the posterior wall of the inguinal canal was repaired.

Histological Examination

Endometriosis was seen in an atrophic phase (fig. 3): the glandular clefts were in part denuded of their lining layer; scanty muscle tissue was interspersed with hyalinised patches of fibrosis; and there was but one central area, surrounding a small blood-filled space, which contained macrophages in any number.

Follow-up

Since her operation the patient had two menstrual periods without discomfort. She is completely relieved of her nagging pain.

Discussion

Though endometriosis is increasingly diagnosed in gynæcological departments I could find no mention of the inguinal variety in six standard general surgical textbooks (four British and two American) and two books on diagnosis.

Diagnosis

Despite the characteristic history a preoperative diagnosis is but rarely made.

Hernia.—Hernia was diagnosed in the majority of reported cases.

The patient of Daro et al. (1954) was not only forewarned of impending menstruation by the appearance of the inguinal pain, but she could foretell whether the loss would be slight or heavy by its intensity. Despite this history, and the swelling which appeared with the onset of the period, the condition was thought to be a strangulated omentocele. ‘ As a general rule ’ reflects Daro, ‘ the symptoms of inguinal endometriosis are rather uniform. . . . However, this condition is so rare that endometriosis is seldom considered as the exciting factor in the train of events.’

In Labry and de Mourgues’s patient (1954) the ‘ hernia ’ appeared suddenly after unaccustomed exercise. It was at first easily reducible and freely transmitted the cough impulse.

In all our three patients a patent canal of Nück was present and in two a cough impulse could be elicited. It is also possible, if the endometrioma is small and mobile, to perform a *reduction en masse* into the inguinal canal. Not only may this lead to the wrong preoperative diagnosis, but even at operation the familiar sight of a peritoneal sac may divert attention from a comparatively inconspicuous endometrial nodule.

Inguinal Lymphadenitis.—Novak (1947) pointed out the pitfall of enlarged inguinal lymph-nodes. As the painful endometrial swelling tends to disappear at the end of each period, spurious cure follows any treatment; and when an antibiotic has been used, this is regarded as proof of its infective origin. Only the first of our patients mentioned spontaneously that her attacks coincided with her periods; the other two had not connected the two events in their own mind.

Unlike inguinal lymphadenitis with its multiple nodules, inguinal endometrioma usually presents as a solitary lump, or in the quiescent state as diffuse induration rather than as a well-defined mass.

Varicocele of the round ligament.—I recently operated on a patient who gave a history of a painful lump in the groin which had appeared three times with the approach of menstrual periods and had disappeared each time shortly after the bleeding had stopped. In the groin she had an ill-defined, partially reducible, tender swelling which transmitted the cough impulse. Exploration for yet another case of endometriosis revealed a tortuous and partially thrombosed pampiniform plexus.

Though uncommonly diagnosed, this condition is not rare, and it shares with endometrioma a periodicity of symptoms which is governed by the menstrual cycle. Varicoceles may become painful and prominent in the premenstrual phase, as they do during the first few months of pregnancy; and thrombosis in the dilated veins results in a firm, tender, irreducible swelling (Tomkinson and Winterton 1955).

Pathology

Three forms of inguinal endometriosis have been described:

1. Sampson (1927) in a classical paper advanced endometriosis of hernial sacs as one of his arguments in favour of his “ spill ” hypothesis. This intraperitoneal variety—which includes endometriomata arising from cysts of the canal of Nuck—could also be derived from endometrial islands in the peritoneal serosa (Ivanoff 1898, Meyer and Kitai 1924).

2. Less commonly, endometriomata are found extraperitoneally. In our 3 cases, though hernial sacs were present, careful naked-eye and microscopic examination revealed no continuity between the intact peritoneum and the endometrioma. For this group “ endometriosis of the round ligament ” is a description *faute de mieux*: in our sections this structure was clearly defined, but in none did it contain ectopic uterine tissue.

3. Endometriomata may also appear in the form of lymph-node deposits, supporting, in MacLeod’s view (1950), the hypothesis of lymphatic spread. Such deposits can be histologically distinguished from the foregoing types by the absence of all muscle tissue.

In our 3 cases one could judge from the microscopic section the approximate phase of the menstrual cycle at which the operation was performed. The inguinal endometrioma removed from a pregnant patient by Rubinstein and Kurzon (1952) showed advanced decidual changes.

In these 3 patients—as in 9 out of 12 cases individually reported in the literature—the endometrioma was on the right side.

Treatment

All symptoms were relieved by excision of the endometrioma in our patients, and in view of their age recurrence is unlikely.

Summary

3 patients with inguinal endometriosis were seen within five months in a surgical outpatient department. All 3 complained of a painful lump in the groin which recurred with each menstrual period.

Unless this history is elicited there may be difficulty in distinguishing this condition from hernia, enlarged inguinal lymph-nodes, or a thrombosed varicocele. Any of these may coexist, and distract attention from the endometrioma at operation.

The literature of inguinal endometriosis is reviewed and three pathological types are recognised: an intraperitoneal and an extraperitoneal variety, and the purely endometrial lymph-node deposit.

Like congenital hernias and undescended testicles this condition appears to be commoner on the right side than on the left.

Treatment by excision brought complete relief in all 3 cases.

I should like to thank Mr. J. R. Stead for permission to publish these cases, for guidance and encouragement, and Miss Gladys H. Dodds for helpful criticism and advice.

tion, (*b*) no significant change, or (*c*) improvement (slight, moderate, or excellent), the films taken at six months were compared with those taken at three months The results are shown in table x, which reveals no essential difference between response of the two groups to treatment

Discussion

In this investigation the same chemotherapy was applied to a group of patients on strict bed rest in hospital and to a similar group of ambulant outpatients The principal aspect under consideration was the effect of exercise, but some of the outpatients had domestic conditions of a type which have always been regarded as adverse in the treatment of tuberculosis—including bad housing conditions, domestic disharmony, and financial difficulties—and most of this group were treated under circumstances far from ideal Since outpatient treatment is being employed on a large scale in this country, it is important to determine whether it increases propagation of the disease The household contacts of both groups of patients are, therefore, being closely supervised, to ascertain the subsequent incidence of infection

Despite the adverse environmental factors in the outpatient group, examination of the position after three months' treatment showed no significant difference between the response of the two groups assessed by fall in E S R, sputum conversion, extent of clearance of lung disease, and cavity closure It is true that the inpatients as a group gained more weight than the outpatients, but this must surely be regarded as reflecting physical inactivity rather than regression of disease, because, as is generally agreed, weight gained by patients in a sanatorium is usually rapidly lost when they resume outside activities

A few patients in both groups have been assessed after completion of six months' treatment Here again there is little difference in the general response, but cavity closure was commoner in the inpatients It would, of course, be unwise to reach any firm conclusion before greater numbers are compared, but it would not be surprising if further experience confirmed this trend Apart from any question of toxæmia or activity of the disease process, there is possibly a mechanical factor in cavity closure which is exploited in many centres by, for example, reversed postural drainage

It is highly probable that enough hospital beds for all newly diagnosed cases of pulmonary tuberculosis will soon be available, and then immediate admission to hospital in the first instance should be the standard procedure Before abandoning bed rest in the treatment of pulmonary tuberculosis it would be necessary to study the long term results in a larger number of patients, but it would seem that, if the results in this preliminary study are confirmed, patients who have ceased to excrete tubercle bacilli might be allowed to resume their everyday occupations much earlier than is now generally thought desirable In addition, patients with pulmonary tuberculosis might be allowed much greater physical freedom than at present with resultant lessening of the burden on nursing staff and diminished tedium for the patients Where domestic conditions are suitable, home treatment could confidently be carried out on an even larger scale than at present, and this form of treatment would undoubtedly be preferred by many patients

Summary

The value of rest in the treatment of pulmonary tuberculosis has been assessed in 141 newly diagnosed cases Alternate patients were admitted to hospital within two weeks of diagnosis, and treated as ambulant outpatients Both groups received the same chemotherapy and were assessed in a standard way

After three months' treatment progress, assessed by reduction of E S R, sputum conversion, cavity closure, and over all radiographic improvement, was as good in 70 ambulant outpatients as in 71 patients on strict bed rest in hospital

After six months' treatment no difference was found between 45 patients on strict bed rest in hospital and 46 ambulant outpatients as regards reduction of E S R, sputum conversion, and over-all radiographic improvement, but cavity closure was commoner in the patients on strict bed rest than in the ambulant outpatients

I should like to thank Dr A W Lees, consultant chest physician, Ruchill Hospital, for his constant interest in this investigation and Dr Agnes Macgregor for her painstaking assessment of the radiographs

A CALCIUM-INFUSION TEST

I URINARY EXCRETION DATA FOR RECOGNITION OF OSTEOMALACIA

B E C NORDIN
M.D Lond, M R C P
MEDICAL REGISTRAR, HAMMERSMITH HOSPITAL, LONDON

RUSSELL FRASER
M D N Z, F R C P
READER IN MEDICINE,
POSTGRADUATE MEDICAL SCHOOL OF LONDON

THE use of calcium infusions in the diagnosis of metabolic bone disease was first suggested by Schilling and Laszlo (1951), who argued that the amount of calcium appearing in the urine after a standard infusion should be inversely related to the "avidity" of the skeleton for calcium, and that this urinary excretion should consequently be slight in osteomalacia (where the skeleton is inadequately calcified) and copious in osteoporosis (where the protein matrix is deficient) They gave some preliminary results obtained with four hour infusions of calcium 450 mg which appeared to support their thesis

Numerous workers have published data on various aspects of calcium infusions (McCance and Widdowson 1939, Baylor et al 1950, Howard et al 1953, Goldman and Bassett 1954, Kyle et al 1954, Schaaf and Kyle 1954, Spencer et al 1954,) but no satisfactory procedure has yet been evolved for the diagnosis of metabolic bone disease We report here a standard procedure which we have applied to patients in whom there was no reason to suspect bone disease and in more than 100 cases of known or suspected bone disorder, we believe it to be of diagnostic value in suspected osteomalacia

Procedure

All the subjects of the experiments reported here were given a low-calcium diet (100–150 mg of calcium and 500–700 mg of phosphorus daily) for three days before and throughout the test Their urine was collected from 6 A M on the third day to 6 A M on the fourth day, and then four-hourly until 6 A M on the fifth day An infusion of calcium gluconate (15 mg of calcium per kg of body-weight) was given in 500 ml of physiological saline solution from 10 A M to 2 P M on the fourth day Samples of blood were taken at the beginning and end of the infusion and at 6 P M and 10 A M next day

The methods used for the estimation of calcium, phosphate, and creatinine have been reported elsewhere (Nordin and Fraser 1954) The net output of calcium after the infusion is expressed as a percentage of the administered dose after deduction of a basal excretion figure calculated from the previous twenty-four hours' urinary output of calcium For the interpretation of the urinary excretion of calcium it suffices to measure the tions were adequate without carbon dioxide and oxygen did however, increase from 3–5 minutes to 18–20 minutes by the twelfth hour after admission Thereafter the depth of coma remained constant while supportive measures were continued for a further fourteen hours Twenty eight hours after admission bemegride 50 mg and amiphenazole 15 mg were administered intravenously, these doses being repeated four times at intervals of five minutes After the fourth injection the patient began to moan and responded to painful stimuli A plantar withdrawal reflex indicating lightening coma (Shulman et al 1955) and tendon reflexes could be elicited for the first time since admission During the next two hours unconsciousness deepened The same dosage of the bemegride and amiphenazole was therefore repeated A plantar withdrawal reflex returned, together with muscle tone and involuntary movements, after the second injection, and a state of light anæsthesia was attained when the total amount had been given An hour later consciousness returned, and within two hours the patient could answer questions although she was confused, and she complained of being unable to see She had been unconscious for about forty eight hours That night she remained awake, no sedative being given Next night she did not sleep despite having gr 1½ each of sodium quinalbarbitone and sodium amylobarbitone Quinalbarbitone gr 6 on each of the two succeeding nights produced only a state of drowsiness, and it was not until the fifth night after regaining consciousness that she actually slept She became rational eighteen hours after consciousness returned, her sight improved rapidly

Seven hours after admission her right thumb and the radial side of her right hand became swollen, and shortly afterwards blisters formed Three days later the skin peeled off and some sensory loss was demonstrated A retrospective diagnosis of frostbite was made Full movement and sensation gradually returned over two weeks Her further progress was uneventful and she made a good recovery

Comments

This case illustrates the dramatic effect which bemegride and amiphenazole can have on barbiturate coma Cerebral stimulants and supportive measures had lightened the level of coma slightly for twenty eight hours—a rate of progress which was in contrast to that produced by bemegride and amiphenazole

Both oxygen and carbon dioxide were essential before treatment with bemegride and amiphenazole The effectiveness of carbon dioxide in maintaining the depth and rate of respiration was rather surprising in view of the fact that the respiratory centre's response to stimulation by carbon dioxide is depressed in barbiturate poisoning (Goodman and Gilman 1955)

It is considered that the hypothermia consequent on prolonged exposure (shown by the frostbite) contributed to the patient's survival by lowering cellular metabolism The small amount of oxygen supplied by the depressed respiratory and circulatory systems was thus able to meet the diminished oxygen requirements of the tissues

Summary

A case of barbiturate coma complicated by hypothermia is reported

The effects of cerebral stimulants of purely supportive measures, and of bemegride and amiphenazole successively in the same patient are described

Hypothermia is thought to have contributed to this patient's survival

Our thanks are due to Prof I G W Hill for permission to publish and for his helpful criticism and to Dr W T Strauss for guidance in the management of this case

PHENOBARBITONE POISONING TREATED WITH BEMEGRIDE

A D F HURDLE
M B Lond
HOUSE PHYSICIAN

B K LANE
M B Lond
HOUSE SURGEON

PADDINGTON GREEN CHILDREN'S HOSPITAL LONDON

BEMEGRIDE (β-ethyl β methylglutarimide, 'Megimide') is said to be of value in the treatment of poisoning by barbiturates (Shaw et al 1954, Harris 1955, Montuschi and Wickenden 1955, Shulman et al 1955, Bingle and Whitwam 1955, Webb 1955, Buckman 1955, Holten 1955, Perinpanayagam 1955, Perinpanayagam et al 1955)

We report here the recovery of a baby from a very large dose of phenobarbitone and comment on the use of bemegride

Case-report

A boy, aged 14 months, was admitted to hospital on Dec 18, 1955, in coma Two days previously his family doctor had prescribed succinylsulphathiazole for a mild gastro intestinal upset Shortly after the first dose the child became drowsy, but administration of the medicine was continued, and he received either five or six doses in thirty six hours During the two days before admission his drowsiness deepened into coma

On admission he weighed 26 lb, his temperature was 100°F, pulse rate 140, and respirations 30 a minute He was well nourished and rather fat He was deeply comatose and responded with only a very slight withdrawal movement to painful stimuli, but was breathing quietly and was not cyanosed His pupils reacted to light and were equal in size The corneal, gag, swallowing, tendon, and abdominal reflexes were all unobtainable The plantar responses were flexor Lumbar puncture showed normal cerebrospinal fluid under a pressure of 240 mm of water

Diagnosis—Phenobarbitone poisoning was diagnosed when analysis by isolation, melting point, elementary analysis, and ultraviolet spectra of the remainder of the medicine showed it to contain phenobarbitone and no sulphonamide By this time the child had been in coma for about thirty six hours At no time was there evidence of respiratory or circulatory failure No rash appeared

Treatment and Progress—It was decided to treat the child with bemegride because of the long continued coma and the large amount of phenobarbitone taken (later estimated at gr 65) A scalp vein infusion was set up and 25 mg bemegride injected into the infusion tubing The child at once stirred and moaned, and his face flushed Two further injections were given at intervals of five minutes After the last of these the face again flushed and the pulse rate quickened from 95 to 120 During one injection the fluid was noticed to be running into the subcutaneous tissues This caused no apparent local reaction During the subsequent one hour and forty minutes nine injections of 25 mg of bemegride were given into the infusion tubing at intervals of five to thirty four minutes Three of these were preceded by amiphenazole (2 4 diamino-5 phenylthiazole hydrochloride, 'Daptazole') 7 5 mg At the end of this period the child was crying had a strong grasp reflex, was moving all limbs and objected to having his eyelids opened Depressing his tongue caused "gagging" The later injections caused spasm of the vein next to the needle, making transfusion difficult, so bemegride was mixed with the transfusion fluid in the bottle The first such bottle contained 500 mg of bemegride and 100 ml of 0 18% sodium chloride with 4 3% dextrose After two hours the child became more deeply comatose, so bemegride 25 mg preceded by amiphenazole 7 5 mg was injected into the tubing The child at once cried and moved his hands The next transfusion bottle contained 620 ml of 5% dextrose and 1000 mg of bemegride No more amiphenazole was given The child's condition gradually improved, and on Dec 20 although he was not fully conscious, his eyes were open and he was reacting vigorously to painful stimuli The transfusion was stopped A few hours later he was sitting up and taking notice of his surroundings He had received 2827 mg of bemegride in eighty hours Throughout treatment the pulse rate was 95–120 and the respirations were 20–25 a minute Two Penicillin and streptomycin were given prophylactically

12 cases of osteomalacia In the "normal" patients the mean serum-calcium level rose from 10·4 to 13·5 mg per 100 ml and in osteomalacia from 9·0 to 11·5 mg per 100 ml, but in none of the patients were there any signs of calcium intoxication, and twenty hours after the end of this infusion the serum calcium level had almost invariably returned to its original value Most of the excess urinary calcium due to the infusion was excreted in the first twelve hours, and we have therefore used the 0–12-hr net total as our index of calcium excretion to express the result of the test

NET URINARY CALCIUM EXCRETION 0–12 HOURS

"Normal"

Fig 2 shows the individual results in the four main groups studied In the "normal" patients the net 0–12 hr excretion was 33–53%, with a mean of 41% and a standard deviation of 7·0 The normal range shown in the charts embraces two standard deviations above and below the mean—i e, 27–55%

Definite Osteomalacia

In proved osteomalacia all the results were below the normal range (see table I) the highest being 26·8% and the lowest 1·5% Within the group there did not appear to be any correlation between the amount of calcium excreted and the severity of the disease, the patient with the highest excretion had multiple Milkman fractures and a short history It should be remembered that the results in vitamin-D resistant osteomalacia have been excluded

TABLE II—CASES OF APPARENTLY SIMPLE STEATORRHŒA SUB DIVIDED BY INFUSION TEST INTO THOSE WITH SUBNORMAL CALCIUM EXCRETION (GROUP A) AND OTHERS (GROUP B)

—	Group A	Group B
12 hr excretion	0–27%	> 27%
No of cases	8	9
No with steatorrhœa for more than 2 yr	6	3
No with bone density definitely normal	1	7
Serum calcium (mean) (mg per 100 ml)	8·2	9·9
Serum phosphorus (mean) (mg per 100 ml)	3·6	3·4
Urinary output of calcium in 24 hr (mean) (mg)	49	94

Group A with low calcium excretion had a longer history of steatorrhœa more suspicious bone radiographs lower serum calcium levels and lower urinary output of calcium on low calcium diet (P > 0·01)

Steatorrhœa without proved Osteomalacia

In 8 of these patients the 0–12 hr net excretion was 27% or less, in 7 it was normal, and in 2 it was increased The reliability of the infusion test depends on whether the 8 patients with low excretion really had a minor degree of osteomalacia and the others not This is suggested by the additional data shown in table II

(1) Most of the patients with a low 0–12 hr excretion (group A) appeared to have had steatorrhœa for a longer time than had group B,

(2) The radiographic density of the bones was questioned by the clinician or the radiologist in all but 1 of group A, but was normal in 7 of 9 in group B,

(3) The mean serum calcium and the 24-hour urinary calcium levels were significantly lower in group A than in group B (P<0·01)

It therefore seems probable that these 8 patients had early osteomalacia, although it could not have been definitely diagnosed in any of them by the conventional procedures, since none of them had definitely abnormal bones on radiography combined with a low Ca × P level in the serum

It is also worth noting that none of them had a raised serum-alkaline phosphatase level (except those with jaundice), a low serum phosphate level, or a raised phosphate/creatinine clearance ratio, in contrast to the definite osteomalacia group

Osteoporosis

All the results were in or above the normal range

TABLE III—EXCRETION OF CALCIUM AFTER INFUSION IN MISCELLANEOUS CASES NOT INCLUDED IN FIG 2

(Vitamin-D resistant osteomalacia excluded)

Diagnosis	Urinary excretion of calcium in 12 hr from start of infusion (% of amount infused)	
Prostatic carcinoma with osteoblastic metastasis	4	
Pyelonephritis with renal failure	6	
Diabetes with thin bones	8	
Hypoparathyroidism	11	
Temporary hypoparathyroidism	14	
Hypoparathyroidism	15	
Acromegaly	16	
Parathyroid tumour with renal failure	17	
Rheumatoid arthritis	19	
Adult cœliac disease	24	
Acromegaly	28	Normal range
Cœliac disease follow up	30	
Osteogenesis imperfecta	30	
Myelosclerosis	31	
Chronic bronchitis	31	
Paget's disease	31	
Hæmochromatosis	33	
Hysterical immobilisation	35	
Chromophobe adenoma	36	
Cœliac disease follow up	36	
Paget's disease	39	
Polyostotic fibrous dysplasia	43	
Osteogenesis imperfecta	43	
Renal stones	48	
Parathyroid tumour with renal failure	49	
Cœliac disease follow up	51	
Intestinal tuberculosis	53	
Hypercalcuria	53	
Cœliac disease follow up	57	
Cœliac disease follow up	65	

Miscellaneous Cases

In most of these cases the net excretion of calcium was normal, but it was less than 27% in 10 (table III) This is hardly surprising in renal failure (2 cases), untreated hypoparathyroidism (3), and prostatic carcinoma with osteoblastic metastases (1) The other 4 "false positives" whose diagnoses are given in table III are at present unexplained

REPRODUCIBILITY

7 patients have received more than one calcium infusion (usually after an interval of at least a year)

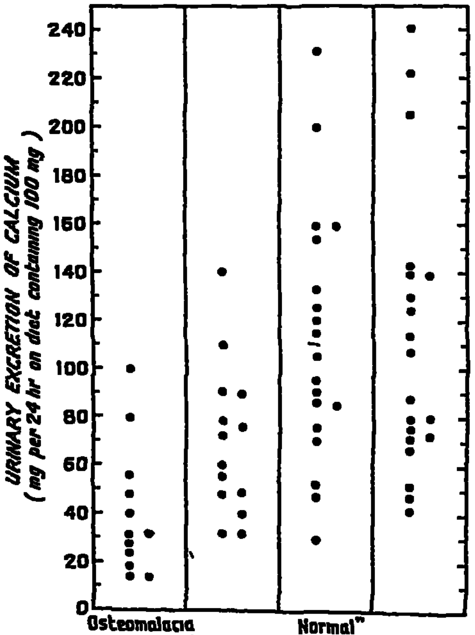

Fig 3—24-hr urinary excretion of calcium on third day of diet containing not more than 100 mg of calcium (same groups as in fig 2)

tions were adequate without carbon dioxide and oxygen did, however, increase from 3–5 minutes to 18–20 minutes by the twelfth hour after admission. Thereafter the depth of coma remained constant while supportive measures were continued for a further fourteen hours. Twenty-eight hours after admission bemegride 50 mg. and amiphenazole 15 mg. were administered intravenously, these doses being repeated four times at intervals of five minutes. After the fourth injection the patient began to moan and responded to painful stimuli. A plantar withdrawal reflex indicating lightening coma (Shulman et al. 1955) and tendon reflexes could be elicited for the first time since admission. During the next two hours unconsciousness deepened. The same dosage of the bemegride and amiphenazole was therefore repeated. A plantar withdrawal reflex returned, together with muscle tone and involuntary movements, after the second injection, and a state of light anæsthesia was attained when the total amount had been given. An hour later consciousness returned, and within two hours the patient could answer questions although she was confused, and she complained of being unable to see. She had been unconscious for about forty-eight hours. That night she remained awake, no sedative being given. Next night she did not sleep despite having gr. $1^1/_2$ each of sodium quinalbarbitone and sodium amylobarbitone. Quinalbarbitone gr. 6 on each of the two succeeding nights produced only a state of drowsiness and it was not until the fifth night after regaining consciousness that she actually slept. She became rational eighteen hours after consciousness returned; her sight improved rapidly.

Seven hours after admission her right thumb and the radial side of her right hand became swollen, and shortly afterwards blisters formed. Three days later the skin peeled off, and some sensory loss was demonstrated. A retrospective diagnosis of frostbite was made. Full movement and sensation gradually returned over two weeks. Her further progress was uneventful and she made a good recovery.

Comments

This case illustrates the dramatic effect which bemegride and amiphenazole can have on barbiturate coma. Cerebral stimulants and supportive measures had lightened the level of coma slightly for twenty-eight hours—a rate of progress which was in contrast to that produced by bemegride and amiphenazole.

Both oxygen and carbon dioxide were essential before treatment with bemegride and amiphenazole. The effectiveness of carbon dioxide in maintaining the depth and rate of respiration was rather surprising in view of the fact that the respiratory centre's response to stimulation by carbon dioxide is depressed in barbiturate poisoning (Goodman and Gilman 1955).

It is considered that the hypothermia consequent on prolonged exposure (shown by the frostbite) contributed to the patient's survival by lowering cellular metabolism. The small amount of oxygen supplied by the depressed respiratory and circulatory systems was thus able to meet the diminished oxygen requirements of the tissues.

Summary

A case of barbiturate coma complicated by hypothermia is reported.

The effects of cerebral stimulants, of purely supportive measures, and of bemegride and amiphenazole successively in the same patient are described.

Hypothermia is thought to have contributed to this patient's survival.

Our thanks are due to Prof. I. G. W. Hill for permission to publish and for his helpful criticism, and to Dr. W. I. Strauss for guidance in the management of this case.

PHENOBARBITONE POISONING TREATED WITH BEMEGRIDE

A. D. F. HURDLE
M.B. Lond.
HOUSE PHYSICIAN

B. K. LANE
M.B. Lond.
HOUSE SURGEON

PADDINGTON GREEN CHILDREN'S HOSPITAL, LONDON

BEMEGRIDE (β-ethyl-β-methylglutarimide; 'Megimide') is said to be of value in the treatment of poisoning by barbiturates (Shaw et al. 1954, Harris 1955, Montuschi and Wickenden 1955, Shulman et al. 1955, Bingle and Whitwam 1955, Webb 1955, Buckman 1955, Holten 1955, Perinpanayagam 1955, Perinpanayagam et al. 1955).

We report here the recovery of a baby from a very large dose of phenobarbitone and comment on the use of bemegride.

Case-report

A boy, aged 14 months, was admitted to hospital on Dec. 18, 1955, in coma. Two days previously his family doctor had prescribed succinylsulphathiazole for a mild gastro-intestinal upset. Shortly after the first dose the child became drowsy, but administration of the medicine was continued, and he received either five or six doses in thirty-six hours. During the two days before admission his drowsiness deepened into coma.

On admission he weighed 26 lb., his temperature was 100°F, pulse-rate 140, and respirations 30 a minute. He was well nourished and rather fat. He was deeply comatose and responded with only a very slight withdrawal movement to painful stimuli, but was breathing quietly and was not cyanosed. His pupils reacted to light and were equal in size. The corneal, gag, swallowing, tendon, and abdominal reflexes were all unobtainable. The plantar responses were flexor. Lumbar puncture showed normal cerebrospinal fluid under a pressure of 240 mm. of water.

Diagnosis.—Phenobarbitone poisoning was diagnosed when analysis by isolation, melting-point, elementary analysis, and ultraviolet spectra of the remainder of the medicine showed it to contain phenobarbitone and no sulphonamide. By this time the child had been in coma for about thirty-six hours. At no time was there evidence of respiratory or circulatory failure. No rash appeared.

Treatment and Progress.—It was decided to treat the child with bemegride because of the long-continued coma and the large amount of phenobarbitone taken (later estimated at gr. 55). A scalp-vein infusion was set up and 25 mg. bemegride injected into the infusion tubing. The child at once stirred and moaned, and his face flushed. Two further injections were given at intervals of five minutes. After the last of these the face again flushed and the pulse-rate quickened from 95 to 120. During one injection the fluid was noticed to be running into the subcutaneous tissues. This caused no apparent local reaction. During the subsequent one hour and forty minutes nine injections of 25 mg. of bemegride were given into the infusion tubing at intervals of five to thirty-four minutes. Three of these were preceded by amiphenazole (2 : 4-diamino-5-phenylthiazole hydrochloride, 'Daptazole') 7.5 mg. At the end of this period the child was crying, had a strong grasp reflex, was moving all limbs, and objected to having his eyelids opened. Depressing his tongue caused "gagging." The later injections caused spasm of the vein next to the needle, making transfusion difficult, so bemegride was mixed with the transfusion fluid in the bottle. The first such bottle contained 300 mg. of bemegride and 400 ml. of 0.18% sodium chloride with 4.3% dextrose. After two hours the child became more deeply comatose, so bemegride 25 mg. preceded by amiphenazole 7.5 mg. was injected into the tubing. The child at once cried and moved his hands. The next transfusion bottle contained 620 ml. of 5% dextrose and 1000 mg. of bemegride. No more amiphenazole was given. The child's condition gradually improved, and on Dec. 20, although he was not fully conscious, his eyes were open and he was reacting vigorously to painful stimuli. The transfusion was stopped. A few hours later he was sitting up and taking notice of his surroundings. He had received 2827 mg. of bemegride in eighty hours. Throughout treatment the pulse-rate was 95–120 and the respirations were 20–25 a minute. Tw

Penicillin and streptomycin were given prophylactically.

urinary excretion of calcium on the previous day, the 0–4-hr urinary excretion of calcium on the test day, the plasma calcium at 0 and 4 hr after the start of the infusion, and, on one of the last samples, the level of ultrafiltrable calcium

Biochemical Methods

Serum and ultrafiltrable calcium were measured either by a modification of Lehmann's ethylene diamine-tetra acetic acid (E D T A) titration procedure * (Lehmann 1953) or more recently by flame photometry * (McIntyre 1956) Urinary calcium was measured by the standard Kramer Tiddall procedure described by King (1951) or, more recently, by flame photometry

Ultrafiltration of serum was done by a method which will be described elsewhere (Nordin et al 1956) The pre-infusion serum was used for this purpose, and it was assumed that the proportion of ultrafiltrable to total calcium remained unaffected by the infusion This assumption has been tested and found valid (Nordin et al 1956)

Calculation

The "4 hr skeletal retention" of infused calcium is estimated at the end of the 4 hr infusion To derive this we deduct from the administered dose the amount of infused calcium which can be accounted for in the extracellular fluid (E C F) at 4 hr and in the 0–4 hr urine, and express the result as a percentage of the infused dose (which is proportional to body-weight)

For the purpose of this calculation the extravascular fluid is assumed to be 15% and the intravascular fluid 5% of the body-weight (Manery 1954) The level of calcium in the extracellular fluid is assumed to be the same as in serum ultrafiltrate (Manery 1954) The amount of infused calcium appearing in the urine over 0–4 hr is estimated by deducting $^1/_6$ of the previous 24-hr urinary output of calcium from the total amount excreted during the infusion—i e , the net or excess excretion of calcium The figure obtained when the sum of these three estimations is deducted from the administered dose is expressed as a percentage of the dose and termed "the 4 hr skeletal retention"

The steps in the calculation are as follows

Increase in extravascular E C F calcium = Rise in ultrafiltrable serum calcium × 15% of body weight (a)

Increase in plasma-calcium = Rise in serum calcium × 5% of body weight (b)

Net urine excretion = Total 0–4 hr calcium less $^1/_6$ previous 24 hours urinary excretion of calcium (c)

Calcium not accounted for in E C F or urine or "4 hr skeletal retention" } = Administered dose −([a] + [b] − [c]) (d) (expressed as percentage of the administered dose)

Alternative procedures for this calculation, when ultrafiltrable calcium has not been measured, are given in the appendix to this article

Patients Studied

We have sufficient data to calculate 4 hr skeletal retention in 54 patients † They fell into the following diagnostic categories

(A) *Normal* this group consisted of 10 patients with no bone disease or disturbance in calcium metabolism The diagnoses were as follows peptic ulcer (3), hypertension, cerebral thrombosis (2), pleural effusion spontaneous pneumothorax, simple obesity, and narcolepsy

(B) *Proved osteomalacia* (8) in 7 patients with steatorrhœa the radiographic and biochemical findings were typical of osteomalacia (as defined in Nordin and Fraser 1956), and in 6 the diagnosis was confirmed by biopsy of the iliac crest 1 patient with osteomalacia immediately following removal of a parathyroid adenoma is included in this group

(C) *Steatorrhœa without proved osteomalacia* 6 cases

(D) *Osteoporosis* this group consisted of 15 patients (13 females and 2 males), of whom 10 had vertebral compression fractures ("definite osteoporosis") The remaining 5 were classified as "probable osteoporosis" and consisted of 3 cases of Cushing s syndrome 1 case of rheumatoid arthritis treated with cortisone for two years, and 1 of postmenopausal backache and radiographically "thin bones"

(E) *Miscellaneous* this group consisted of 15 patients with diseases which might involve bone metabolism and 1 elderly patient with vertebral crush fractures without evident cause whom we have been unable to clarify (see below)

Some of the patients received a low calcium diet before the infusion but others did not No distinction has been made between the two groups

Results

"4 HR SKELETAL RETENTION" (INDIVIDUAL RESULTS BY DIAGNOSTIC CATEGORIES) (FIG 1)

(A) "*Normal*" *Patients*

The "4 hr skeletal retention" in the 10 "normal" patients was 50–62% of the dose (mean 55 2%) The standard deviation is 3 3%, and two standard deviations above and below the mean embrace the range 48 6–61 8% Since the normal group consists of only 10 patients, we have shown the absolute normal range on our graphs until we have collected further data

(B) *Osteomalacia*

In all the 8 patients with osteomalacia the 4 hr retention of calcium was above the normal range The highest retention (88%) occurred in the patient who had just undergone parathyroidectomy

(C) *Steatorrhœa*

Of 7 patients with steatorrhœa without obvious osteomalacia, 5 retained more than 62% of the dose, 1 patient retained 60%, and 1 46%

(D) *Osteoporosis*

11 patients with osteoporosis retained less than 50% of the dose of calcium at 4 hr The retention in 4 patients was within the normal range 1 of these was a "possible" osteoporosis, and the 3 others had been treated with hormones for from 4 months to 5 years Only 1 of the patients with a low skeletal retention had received any treatment at the time of the infusion

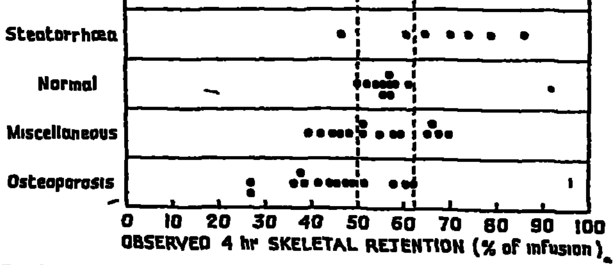

Fig 1—"4-hr skeletal retention" of calcium infusion in 5 main groups of patients studied

Note (1) normal range of 50–62%, (2) high skeletal retention in each of 8 cases of definite osteomalacia due to steatorrhœa and in 5 of 7 cases of steatorrhœa without obvious osteomalacia, and (3) subnormal skeletal retention in 11 of 15 cases of osteoporosis (contrast 0–12 hr excretion on same tests in fig 2 of Nordin and Fraser [1954], abnormal in only 4 of 15) tions were adequate without carbon dioxide and oxygen did, however increase from 3–5 minutes to 18–20 minutes by the twelfth hour after admission Thereafter the depth of coma remained constant while supportive measures were continued for a further fourteen hours Twenty-eight hours after admission bemegride 50 mg and amphenazole 15 mg were administered intravenously, these doses being repeated four times at intervals of five minutes After the fourth injection the patient began to moan and responded to painful stimuli A plantar withdrawal reflex indicating lightening coma (Shulman et al 1955) and tendon reflexes could be elicited for the first time since admission During the next two hours unconsciousness deepened The same dosage of the bemegride and amphenazole was therefore repeated A plantar withdrawal reflex returned, together with muscle tone and involuntary movements, after the second injection, and a state of light anæsthesia was attained when the total amount had been given An hour later consciousness returned, and within two hours the patient could answer questions although she was confused, and she complained of being unable to see She had been unconscious for about forty eight hours That night she remained awake, no sedative being given Next night she did not sleep despite having gr $1^1/_2$ each of sodium quinalbarbitone and sodium amylobarbitone Quinalbarbitone gr 6 on each of the two succeeding nights produced only a state of drowsiness, and it was not until the fifth night after regaining consciousness that she actually slept She became rational eighteen hours after consciousness returned, her sight improved rapidly

---

* Compared estimations were about equivalent on these methods (McIntyre 1956)

† All those patients tested by July, 1955, for whom were available in addition to urinary data, the required data of ultrafiltrable calcium and the necessary two serum samples, measured by E D T A or flame photometry In 1 osteoporotic patient the ultrafiltration measurement was not available, and so the value obtained by the appendix methods has been used

Seven hours after admission her right thumb and the radial side of her right hand became swollen, and shortly afterwards blisters formed Three days later the skin peeled off, and some sensory loss was demonstrated A retrospective diagnosis of frostbite was made Full movement and sensation gradually returned over two weeks Her further progress was uneventful and she made a good recovery

Comments

This case illustrates the dramatic effect which bemegride and amphenazole can have on barbiturate coma Cerebral stimulants and supportive measures had lightened the level of coma slightly for twenty eight hours—a rate of progress which was in contrast to that produced by bemegride and amphenazole

Both oxygen and carbon dioxide were essential before treatment with bemegride and amphenazole The effectiveness of carbon dioxide in maintaining the depth and rate of respiration was rather surprising in view of the fact that the respiratory centre's response to stimulation by carbon dioxide is depressed in barbiturate poisoning (Goodman and Gilman 1955)

It is considered that the hypothermia consequent on prolonged exposure (shown by the frostbite) contributed to the patient's survival by lowering cellular metabolism The small amount of oxygen supplied by the depressed respiratory and circulatory systems was thus able to meet the diminished oxygen requirements of the tissues

Summary

A case of barbiturate coma complicated by hypothermia is reported

The effects of cerebral stimulants of purely supportive measures, and of bemegride and amphenazole successively in the same patient are described

Hypothermia is thought to have contributed to this patient's survival

Our thanks are due to Prof I G W Hill for permission to publish and for his helpful criticism, and to Dr W T Strauss for guidance in the management of this case

B K LANE
M B Lond
HOUSE SURGEON

PADDINGTON GREEN CHILDREN'S HOSPITAL, LONDON

BEMEGRIDE (β ethyl β methylglutarimide 'Megimide is said to be of value in the treatment of poisoning b barbiturates (Shaw et al 1954, Harris 1955, Montuch and Wickenden 1955, Shulman et al 1955, Bingle an Whitwam 1955, Webb 1955, Buckman 1955, Holte 1955, Perinpanayagam 1955, Perinpanayagam et al 1955)

We report here the recovery of a baby from a ver large dose of phenobarbitone and comment on the u of bemegride

Case-report

A boy, aged 14 months, was admitted to hospital o Dec 18, 1955, in coma Two days previously his famil doctor had prescribed succinylsulphathiazole for a mil gastro intestinal upset Shortly after the first dose the chil became drowsy, but administration of the medicine wa continued, and he received either five or six doses in thirty si hours During the two days before admission his drowsine deepened into coma

On admission he weighed 26 lb his temperature wa 100°F, pulse rate 140, and respirations 30 a minute He wa well nourished and rather fat He was deeply comatose an responded with only a very slight withdrawal movement t painful stimuli, but was breathing quietly and was no cyanosed His pupils reacted to light and were equal in siz The corneal, gag, swallowing, tendon, and abdominal refle were all unobtainable The plantar responses were flexor Lumbar puncture showed normal cerebrospinal fluid under pressure of 240 mm of water

Diagnosis —Phenobarbitone poisoning was diagnosed whe analysis by isolation, melting point, elementary analysis a ultraviolet spectra of the remainder of the medicine show it to contain phenobarbitone and no sulphonamide By th time the child had been in coma for about thirty six hours At no time was there evidence of respiratory or circulator failure No rash appeared

Treatment and Progress —It was decided to treat the chil with bemegride because of the long continued coma and th large amount of phenobarbitone taken (later estimated a gr 35) A scalp vein infusion was set up and 25 mg bemegrid injected into the infusion tubing The child at once stirre and moaned, and his face flushed Two further injectio were given at intervals of five minutes After the last o these the face again flushed and the pulse rate quicken from 95 to 120 During one injection the fluid was notice to be running into the subcutaneous tissues This caused n apparent local reaction During the subsequent one hou and forty minutes nine injections of 25 mg of bemegride we given into the infusion tubing at intervals of five to thirty fi minutes Three of these were preceded by amphenazol (2 4 diamino 5 phenylthiazole hydrochloride, 'Daptazole 7 5 mg At the end of this period the child was crying, ha a strong grasp reflex, was moving all limbs and objected t having his eyelids opened Depressing his tongue caus 'gagging " The later injections caused spasm of the ve next to the needle, making transfusion difficult, so bemegri was mixed with the transfusion fluid in the bottle The fir such bottle contained 500 mg of bemegride and 100 ml o 0 18% sodium chloride with 4 3% dextrose After two hour the child became more deeply comatose, so bemegride 25 m preceded by amphenazole 7 5 mg was injected into th tubing The child at once cried and moved his hands Th next transfusion bottle contained 620 ml of 5% dextro an 1000 mg of bemegride No more amphenazole was give The child's condition gradually improved, and on Dec 2 although he was not fully conscious, his eyes were open an he was reacting vigorously to painful stimuli The transfu was stopped A few hours later he was sitting up and takin notice of his surroundings He had received 2527 mg o bemegride in eighty hours Throughout treatment the pul rate was 95–120 and the respirations were 20–25 a minu Th Penicillin and streptomycin were given prophylactically in osteoporosis the 0–12-hr urinary excretion did not exceed the normal range, and so we must assume that some of the excess calcium circulating at 4 hr was either deposited in the skeleton between 4 and 12 hr or also was lost in the fæces—in either case to an extent greater than in healthy people Either of these abnormalities might be possible consequences of an excessive rise of plasma-calcium level as happened in these patients Thus our results suggest that the "4-hr skeletal retention" would be more sensitive to defective deposition of calcium than the 0–12-hr urinary excretion

The findings in the other patients suggest that the '4 hr skeletal retention" is a reliable index of the skeleton's avidity for calcium The normal range is slightly narrower than that of the 0–12-hr urinary excretion, and it still reveals the excessive skeletal avidity of all the osteomalacia patients tested Indeed, as noted, it is striking how closely the '4 hr skeletal retention" reflects the final retention of calcium, or that not excreted in the 0–12-hr urinary excretion except in osteoporosis and in defective skeletal avidity For the recognition of osteomalacia due to steatorrhœa, however, this complication of the test by the estimation of serum levels is unnecessary, and the 0–12-hr urinary excretion of calcium reliably reveals the excessive avidity for calcium

The low '4-hr skeletal retention' which we found in osteoporosis does not necessarily imply any abnormality of the protein matrix in these cases, as suggested by Albright and Reifenstein (1948) The only definite statement that can be made about the osteoporotic skeleton is that it contains less bone than does a healthy one (Follis 1954) This reduction in mass, with its associated reduction in surface area, may explain the reduced rate of deposition of calcium in the skeleton during the test

The practical value of the calcium infusion test in osteoporosis remains to be seen but the possession of even one biochemical criterion of osteoporosis should be valuable to workers in this field particularly those interested in studying the effects of therapy, and it is just possible that the procedure we have described may meet this need

Summary

The results of the calcium infusion test, described in the previous paper, have been analysed to show, in 54 patients the '4 hr skeletal retention" of calcium—the proportion of the infused calcium neither in the urine nor in the extracellular fluid at 4 hr

In 10 "normal" patients this '4 hr skeletal retention" was 50–62% (mean value 55%) In all of 8 patients with osteomalacia due to steatorrhœa, and in 5 of 7 patients with steatorrhœa without obvious osteomalacia, this "4 hr skeletal retention" was above the normal

In 11 of 15 patients with osteoporosis the "4-hr skeletal retention" was below the normal, although the 0–12 hr urinary excretion of calcium was abnormal in only 4 of them We suggest that this "4-hr skeletal retention' may offer a biochemical criterion for osteoporosis

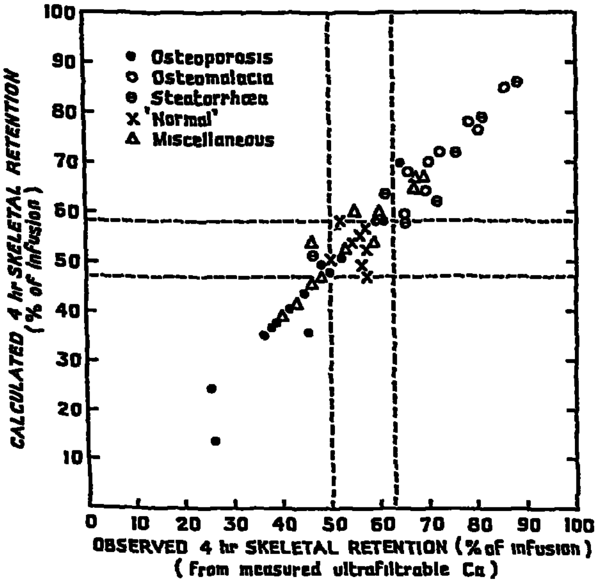

Fig 3—Correlation between observed 4-hr skeletal retention and that calculated by formula correcting for serum protein levels See appendix

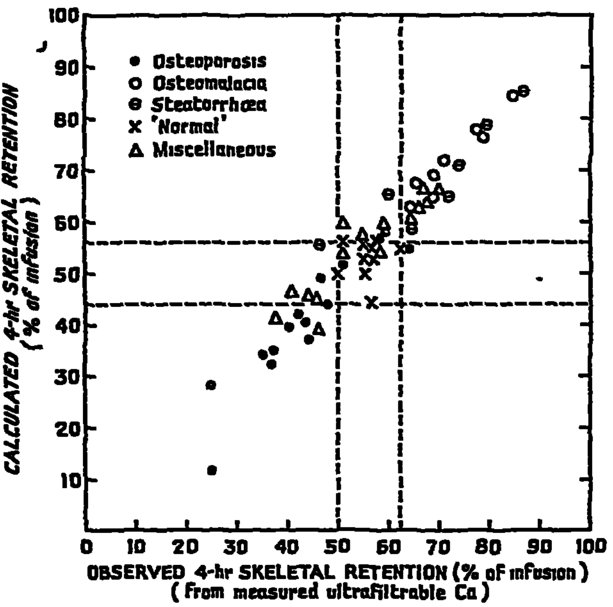

Fig 4—Correlation between observed '4-hr skeletal retention' and that calculated assuming normal serum levels See appendix

We wish to acknowledge with gratitude the assistance of Miss Sheila Stewart, B SC, and of the sisters and nurses of Hammersmith Hospital, and to thank Mr C R Brecknall and Mr F Saunders of the illustration department of the Postgraduate Medical School of London for the illustrations, and several colleagues for referring patients

Appendix

The procedure described above involves the ultrafiltration of serum We have however, recalculated all our data in two ways which eliminates this necessity

(a) *Correcting for plasma protein levels* (fig 3)

We may calculate the percentage of calcium which is ultrafiltrable from the albumin and globulin concentrations according to a formula which we are publishing elsewhere (Nordin et al 1956) (Protein bound Ca % = −3 1 + 7 6 × albumin (g per 100 ml) + 2 9 × globulin (g per 100 ml.))

In fig 3 the results obtained by this calculation are compared with those obtained in the same cases by measurement of the ultrafiltrable calcium It will be seen that there is very little difference in the results although the absolute normal range by this calculation becomes 47–58 instead of 50–62% The number of osteoporotic patients with subnormal retention becomes 9 or 10 instead of 11 out of 16

(b) *Assuming normal plasma proteins* (fig 4)

We have assumed that, with normal plasma proteins, the ultrafiltrable calcium is always 67% of the total serum calcium (Nordin et al 1956)

The total circulating extracellular calcium thus becomes the sum of

(i) Rise in serum calcium level × 5% of body weight and

(ii) Rise in serum calcium level $\times \frac{67}{100} \times$ 15% of body weight

This solves to rise in serum calcium level × 15% of body weight tions were adequate without carbon dioxide and oxygen did, however increase from 3–5 minutes to 18–20 minutes by the twelfth hour after admission Thereafter the depth of coma remained constant while supportive measures were continued for a further fourteen hours Twenty eight hours after admission bemegride 50 mg and amphenazole 15 mg were administered intravenously, these doses being repeated four times at intervals of five minutes After the fourth injection the patient began to moan and responded to painful stimuli A plantar withdrawal reflex indicating lightening coma (Shulman et al 1955) and tendon reflexes could be elicited for the first time since admission During the next two hours unconsciousness deepened The same dosage of the bemegride and amphenazole was therefore repeated A plantar withdrawal reflex returned, together with muscle tone and involuntary movements, after the second injection, and a state of light anæsthesia was attained when the total amount had been given An hour later consciousness returned, and within two hours the patient could answer questions although she was confused, and she complained of being unable to see She had been unconscious for about forty eight hours That night she remained awake, no sedative being given Next night she did not sleep despite having gr 1½ each of sodium quinal barbitone and sodium amylobarbitone Quinalbarbitone gr 6 on each of the two succeeding nights produced only a state of drowsiness, and it was not until the fifth night after regaining consciousness that she actually slept She became rational eighteen hours after consciousness returned, her sight improved rapidly

Seven hours after admission her right thumb and the radial side of her right hand became swollen, and shortly afterwards blisters formed Three days later the skin peeled off, and some sensory loss was demonstrated A retrospective diagnosis of frostbite was made Full movement and sensation gradually returned over two weeks Her further progress was uneventful and she made a good recovery

CONTROL OF ALDOSTERONE EXCRETION BY CHANGES IN VOLUME OF BODY-FLUID

ALEX F MULLER
M D

ANNE M. RIONDEL
Ing chem

RENÉ S MACH
M D

From the Department of Medicine in the University of Geneva, Clinique Thérapeutique, Hôpital Cantonal

VASOPRESSIN, a long-acting extract of the posterior lobe of the pituitary gland administered to normally hydrated people for three days produces acute retention of water and the resulting abnormal increase of the body-fluid evokes by homœostasis renal loss of sodium and chloride (Leaf et al 1953) The urinary excretion of sodium has also been increased by acutely overloading healthy people with water (Stewart and Rourke 1942) and by giving an infusion of hypotonic saline solution (Strauss et al 1952)

According to Leaf et al (1953) this loss of electrolyte can be prevented by administering either corticotrophin or a low-sodium diet Since the latter stimulates the urinary excretion of aldosterone, it seems reasonable to assume that the increased renal excretion of sodium which follows the increase of body-fluid may be due to diminished production of aldosterone, and that the striking retention of sodium after vasopressin has been withheld might be secondary to increased secretion of aldosterone by the suprarenal cortex

Methods

The subject studied was a healthy man, aged 32, maintained on a constant low sodium diet and a fluid intake of 2000–2500 ml a day After an initial control period posterior pituitary extract was administered intramuscularly as vasopressin tannate in oil every twelve hours

Urine was collected every twelve or twenty four hours from 7 A.M and analysed for sodium in a flame photometer The urinary 17 hydroxycorticoids were determined according to a modification of Reddy's method (Hertoghe et al 1955) Aldosterone was analysed chromatographically after acidification of the urine at pH 1 for twenty four hours (method *d* of Neher and Wettstein [1955]) *

Results

The accompanying figure shows the typical response of a healthy person to vasopressin tannate over two and a half days, as described by Leaf et al (1953) The retention of water as the antidiuretic effect of vasopressin is seen in the abrupt decrease in volume of the urine and the corresponding increase in body-weight As expected on the second and, especially the third days of administration of vasopressin the urinary sodium increased Though the appearance of increased excretion of electrolytes was delayed making a direct action of vasopressin on sodium very unlikely, there was an immediate decrease in the urinary excretion of aldosterone following the retention of water and the abnormal increase of body fluid It is therefore highly probable that this decreased urinary excretion of aldosterone as a direct consequence of increase of body-fluid, caused secondarily the delayed renal loss of sodium

The withholding of vasopressin was followed by a large water diuresis and a loss of body weight This significant diminution of body-fluid took place pari passu with an increased urinary excretion of aldosterone The latter was the immediate cause of the pronounced retention of sodium three days after vasopressin had been withheld The fact that the urinary excretion of aldosterone remained high for several days can be explained by the body-fluid volume expressed as body-weight being below the level found at the beginning of the study

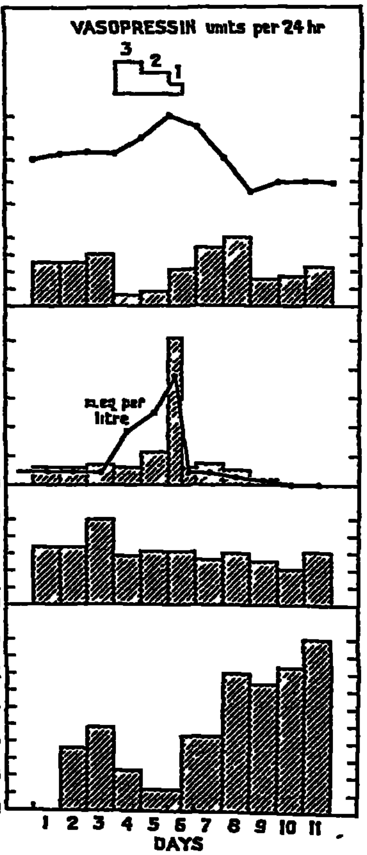
During the whole of this investigation the amount of urinary 17-hydroxycorticoids did not show any significant change

Discussion

Leaf et al (1953) interpreted the renal loss of sodium resulting from retention of water as a homœostatic response to abnormal increase of body-fluid That this increased urinary excretion of electrolytes in man is a direct effect of decreased production of aldosterone is suggested by the results of the present study The sequence of events after the administration of vasopressin is as follows (1) retention of water, (2) decrease of secretion of aldosterone as a homœostatic response to increase of body-fluid, and (3) increase in urinary excretion of sodium as a direct consequence of the diminution of aldosterone

Withholding the vasopressin reverses the process (1) a large water diuresis causes a loss of weight, (2) the diminution of body-fluid stimulates the production of aldosterone, and (3) pronounced renal retention of sodium

The significant variations in the amount of aldosterone excreted, in spite of a constant amount of 17-hydroxycorticoids excreted throughout the whole study, strongly suggest an adaptive mechanism which independent of any effect of corticotrophin and acting through some volume of body-fluid, regulates the secretion of aldosterone in favour of homœostasis In a recent similar experiment (A F Muller and A M Riondel, unpublished), however, exogenous corticotrophin was found to influence the excretion of aldosterone The 'rebound' production of aldosterone after vasopressin has been withheld was much increased and hastened by an injection of corticotrophin twelve hours after the last dose of vaso-



Effect of vasopressin on body weight, volume of urine and urinary excretion of sodium, 17 hydroxycorticoids and aldosterone The relatively high values of aldosterone are due to the constant low-sodium diet with its effect on the volume of the body fluid use of the frame was an essential part of their regime, the head of the femur could always be brought down but was commonly left standing out from the acetabulum 75 operations had been performed and only once had they failed to find an inverted limbus, which might be very large, the limbus could not be everted The position of subsequent plaster immobilisation depended on the degree of internal rotation required to reduce the head fully, in 1 case posterior capsulotomy had been needed to permit this Three weeks later a rotation osteotomy was done, leaving the upper fragment unmoved and rotating the shaft to the neutral position Five weeks later the patients were left free from splintage and early weight bearing was permitted The total duration of treatment had now been reduced to fourteen weeks Further dislocation had taken place in 3 cases, either because the limbus had not been excised or because derotation had been insufficient and further operation was required All cases had a range of movement 90% or more of normal

---

* We wish to thank Dr A Wettstein and Dr R Neher for their valuable help in setting up this method in our laboratory

Slipping of Upper Femoral Epiphysis

Mr P H Newman reported the results of surgical treatment of slipping of the upper femoral epiphysis in 30 cases The results were excellent in 23, good in 8 fair in none, and poor in 8 If there was less than one third diameter posterior and less than one quarter diameter medial displacement the femoral head was pinned in situ Because of the difficulty of insertion into the epiphysis, the danger of damaging its blood supply, and the possibility of a subtrochanteric fracture at the point of insertion, he had abandoned the use of a Smith Petersen nail and used a modification of Moore's pins In this first group only 1 out of 19 had a poor result If the position was unacceptable an attempt to improve it by very gentle manipulation was made and pins were inserted if adequate reposition was obtained There were 7 cases in this group, perfect reduction was rarely obtained, but in the single poor result the patient had had a stiff hip before operation Where closed reduction failed open reduction through an anterior approach, with excision of a wedge of bone where necessary was performed A pin inserted up the neck ready before the open correction was done could be driven on immediately the head was reduced, and this prevented loss of position during the later stages of the operation The results had been poor in 3 out of 9 Treatment of the fourth group was by subtrochanteric osteotomy, which he had now abandoned Treatment in these cases was urgent Poor results followed avascular necrosis and operations on hips already stiff from delayed diagnosis or prolonged traction In such cases two months' physiotherapy to mobilise the hip and improve the local blood supply was indicated before operation could be considered

Mr A M Rennie (Aberdeen) reported his results in 15 cases Avascular necrosis had developed in 3, and he agreed that operations on stiff hips, which had resulted in 2 poor results in his own series must be avoided

Dr E Thomasen (Aarhus) had tried to stimulate fusion by drilling across the epiphysial plate keeping the patient eight weeks in bed on traction without plaster fixation Occasionally he had left a Kirschner wire across the plate for a few months as additional fixation A subcapital wedge osteotomy with drilling and fixation by Kirschner wires was reserved for later cases Avascular necrosis had developed in 3 out of 14 cases

Fractured Neck of Femur Treated by Compression

Mr John Charnley (Manchester) described the treatment of fractures of the neck of the femur by compression With present methods a third failed to unite within the first year He had been using a coarse threaded screw in the femoral head the smooth shaft of this screw passed through a socket inserted into the femoral neck and fixed by a plate to the femoral shaft A nut and spring allowed compression to 25 lb The angle was fixed at 120 Special tools were required and while all other movements were prevented the spring maintained compression between head and neck should absorption of the latter occur The apparatus permitted measurement of the degree of shortening taking place in the neck Cases fell into two groups one in which extrusion of the bolt was seen to cease after three months and another in which it continued to progress for a year or more Of 33 cases available for study 82% united satisfactorily

Arthrodesis of Hip

Mr McKee reported the results in 50 cases of arthrodesis of the hip by a lag screw reviewed at least two years after operation The operation was done through a lateral approach Afte removal of the articular cartilage the hip was fixed by a lag screw inserted up the femoral neck and into the ilium The neck was drilled out to allow the smooth shaft of th screw free passage when final compression was applied an it was important to ensure that all the threaded part was i the ilium The greater trochanter was removed and used a an iliofemoral graft In 76% of cases no additional plast fixation was used The screw broke in 16%, but in only ha of these did it need to be removed this complication ha not occurred in the last 38 cases There had been 2 death 1 from delayed shock and the other from coronary thrombo In only 1 case had union failed to take place owing to a ischaemic necrosis in the femoral head Final results show 34% excellent, 32% good, and 28% fair

Knock-knee in Children

Mrs M Morley reported an investigation into knock kne in children In general knock knee became increasingl common and severe up to the age of 3½ years, after whic it diminished steadily Sex made no difference to th incidence, but the more severe the knock knee the great was the weight of the children No correlation with heigh was found, and valgus ankles and flat feet (the latter almo universal in the very young) diminished with age and wer unrelated to knock knee She had failed to find any association between knock knee and the age of first walking th duration of breast feeding, additional vitamins, or the lengt of time spent in bed because of illness

Paralytic Scoliosis

Mr J I P James had attempted to correlate the distribution of paralysis with the curve patterns in paralytic scolios Of 193 cases, divided into high thoracic, thoracic thoracolumbar, lumbar, combined thoracic and lumbar, and "telescopic" spine he had chosen the high thoracic, thoracolumbar, and lumbar for special study When the onset was before the age of 5 the curvature usually exceeded 100° but if delayed till after the age of 10 it was usually less than 70 The high thoracic curve usually started at T1 In contradistinction to Colonna he had failed to find any correlation between paralysis of the shoulder girdle or proximal segment of the upper limb in this type of curvature The erector spinae was usually normal and there was no significant relationship to abdominal paralyses He had however, found almost constant paralysis of the intercostal muscles on the convex side, and in contradistinction to idiopathic curves the ribs were not spread on this side but were crowded and hung almost vertically so that they were obscured by the spine on the anteroposterior radiograph A cine radiographic film showed the ribs on the concave side moving well on respiration in contrast to those on the convex side In thoracolumbar curves with the apex at D11 or D12, and in lumbar curves weakness of the lateral flexors on the convex side was constant Weakness of the erector spinae, anterior abdominal muscles psoas, glutei, or lower limbs was apparently unrelated The only other factor that he believed to be significant was gravity On the M R C scale adequate muscle charting of the trunk muscles was extremely difficult and of the intercostal obviously impossible by clinical methods

Fractures and Dislocations of Cervical Spine

Mr F C Durbin (Exeter) discussed 75 cases of fracture and dislocations of the cervical spine seen in a ten year period 12 of these involved atlas and axis and were excluded from consideration The rest were chiefly in young active males road accidents being the commonest cause Where paraly was absent and there were other serious injuries, the lesion was easily missed A fractured spinous process always implied damage to the interspinous ligament In the injuries if no dislocation was present he advised that radiographs in flexion carefully controlled by the surgeon should be taken to test the stability of the spine In over half the cases with dislocation the cord or nerve roots were injured In 26 the cord was injured, in 15 there was complete quadriplegia and 14 of these patients had died He recommended gradual reduction by skull traction with Crutchfield ice tong callipers which were safe and effective if tightened daily The 4 failures of reduction by this method were due to locked facets which needed operative reduction Simpl immobilisation after reduction was not sufficient, recurrence of displacement as shown by radiographs in flexion [illegible] occurred in 8 cases 3 of them even after six months in plaster and 2 associated with fractures of a spinous process [illegible]

Histology

The excised nodule contained uterine glandular and muscular elements interspersed with blood filled spaces (fig 2) Red blood cells also appeared in the lumen and stroma of the glands which were lined by darkly staining columnar cells In several sections the round ligament could be seen traversing the central part of the endometrioma The endothelial layer of the hernial sac was separated from both by dense fibrous tissue

THE SECOND CASE

About Mrs B, a clerk aged 49 her family doctor wrote there is a cystic, tense swelling in the right groin At first I thought it was a hernia but I am now inclined to think that it might be a hydrocele of the canal of Nuck If it is then it is the first I have seen in twenty years

The swelling had appeared abruptly three months previously it had rapidly increased in size and had become agonisingly painful On direct questioning the patient readily confirmed that the onset had coincided with the first day of a menstrual period and that after menstruation the symptoms had disappeared as quickly as they had come

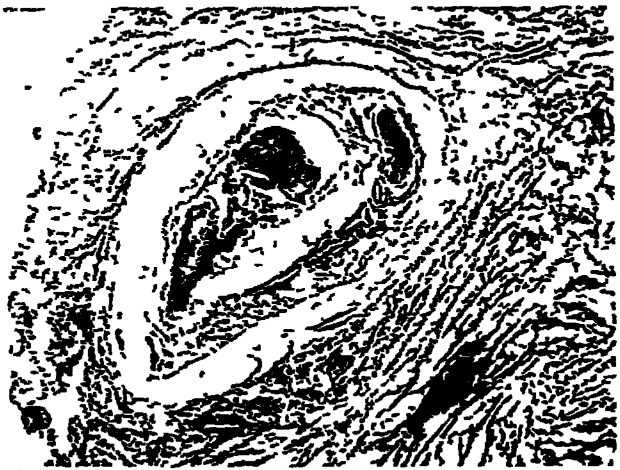


Fig 2—Microphotograph of the round ligament and inguinal endometrioma in case 1 (Low magnification Hæmatoxylin and eosin.)

The next ' acute attack had occurred during the following period, four weeks later and the latest episode had ended three weeks before admission

Over the past twenty years she had noticed from time to time tenderness and mild discomfort in her right groin but this was not associated with menstruation Her cycles had been regular and there were no gynæcological symptoms She had been married for twenty one years and though both she and her husband had been anxious to have a family, their union had remained childless

Examination

In the right groin a firm non tender swelling the size of a walnut was palpable One observer in addition to the patient's doctor who had seen her in the acute phase, recorded a cystic sensation imparted by the lump but there was no suspicion of a cough impulse and the mass was not only irreducible but firmly anchored to underlying structures The skin was freely moveable over it and of normal appearance Rectal examination was negative

Operation

Operation was preceded by a pelvic examination under anæsthetic The uterus was slightly and somewhat irregularly enlarged but no abnormality of the external genitalia or uterine adnexa was found

Exploration through an inguinal skin crease incision revealed a mass issuing from the external ring and obscuring the round ligament and its companion structures It had the colour and consistence of scar tissue but cystic spaces, varying in size from a pin head to a lentil were visible as dark patches through the transparent fibrous covering Unlike the mass in our first patient this one showed no tendency to infiltrate, indeed a clear plane of cleavage made it appear encapsulated The inguinal canal sheltered an empty indirect sac whose distal extremity was lightly tethered to it The hernial sac was transected its proximal end was sutured, and the contents of the inguinal canal were excised

Pathology

The excised mass had an almost honeycomb appearance the content of the cysts, reminiscent of that of ovarian ' chocolate cysts ' stained their lining dark brown On everting the fundus of the hernial sac there was no evidence of endometrial tissue arising directly from the peritoneal lining

Tubular glands surrounded by abundant musculature, were seen under the microscope They showed the characteristic tortuosity and scalloping of premenstrual endometrium A number of macrophages with deeply staining mottled cytoplasm were congregating in the subendometrial layer

Follow up

Menstruation started three days after operation and passed without discomfort or reappearance of the lump The next two menses were similarly uneventful

THE THIRD CASE

Mrs C aged 40 complained of a nagging pain ' in the right groin of three or four years duration which not only limited her outdoor activities but had lately started to interfere with her regular household duties In reply to leading questions she said that though the discomfort was present most of the time, it was worse during menstruation. She had also noticed on occasion a small swelling in the groin but this, she maintained had been present on and off since childhood

She had been married for twenty four years but there had been no pregnancies

Examination

In the right groin faith rather than touch demonstrated an irreguler thickening overlying and adherent to the body of the pubis This area was moderately tender and the patient complained of aching after palpation There was no cough impulse and she had no palpable lymph nodes Routine investigations and pelvic examination under anæsthetic again revealed nothing abnormal

Operation

Operation was performed two days after the end of a menstrual period The principal finding was a mass about an

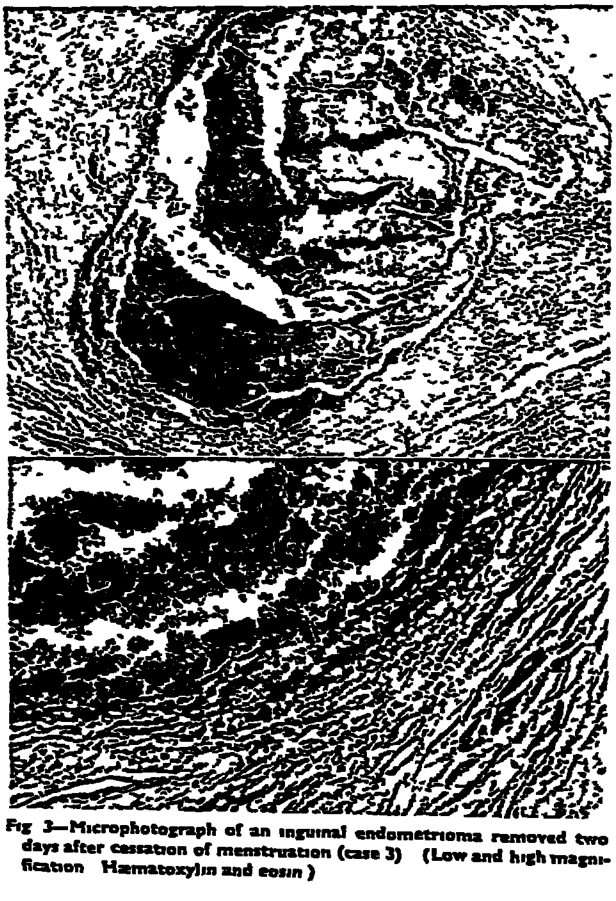

Fig 3—Microphotograph of an inguinal endometrioma removed two days after cessation of menstruation (case 3) (Low and high magnification Hæmatoxylin and eosin)

year to soft tissue, from an atmosphere with a radon content of 3×10^{-13} curie per litre of radon This figure would of course be very much higher, and may be of considerable significance, under higher radioactive atmospheric conditions

Estimates of total gonad dose rates vary from 90 m rad per year for outdoor workers in Leeds to 146 m rad per year for Swedes living in concrete houses

Estimates of the total lung dose-rate from background sources have also been made In addition to soft tissue radiation from "external" background sources and "internal" radiation by ^{40}K, further irradiation will occur as a result of inhaling particulate matter carrying radon and thoron daughter products The resultant lung dosage from this source will depend upon many variable factors, the chief of which are the solubility of the inhaled material, the size of the inhaled particles, the conditions of inhalation, and the ventilation rate High lung ventilation rates reduce radon and thoron doses by a factor of about 4 In view of the variables involved, a number of assumptions have been made The total dose rate to superficial bronchial tissues is about 300 m rem per year—three times that calculated for general soft tissue elsewhere in the body

Lastly, Professor Spiers presented the results of calculations on the quantities of two fission products—cæsium and strontium—which would be required to produce tissue dose rates equal to those already being received by body-tissues from natural sources Both cæsium and strontium, which are long-lived, are capable of being taken into the body structure, and at the present time accidental ingestion of radioactive materials must be regarded as at least a possible accompaniment of nuclear-energy development

Radioactive cæsium (^{137}Cs) may be expected to follow potassium in behaviour and distribution, and it is calculated that a body content or burden of 0 6 microcuries is required to give a soft tissue dose rate equal to the background rate of 100 m rem per year Radioactive strontium (^{90}Sr) and its daughter yttrium (90) are known to be taken up in bone, and are estimated to require a body burden of 45×10^{-9} curie to give an average dose rate to osteocytes equal to that from the natural background The International Commission on Radiological Protection recommend the introduction of a factor of 5 to allow for the fact that strontium concentrations in bone may be five times higher than those observed for radium, if this is the case, a body burden of 9×10^{-9} curie would be the equivalent strontium burden to give a dose rate to bone equal to the natural background

Professor Spiers reiterated that the radiation dose rate from natural sources has been an inevitable accompaniment of Man's life and evolution, and that it must therefore be at least a reasonably tolerable factor in his environment It follows that in the assessment of "permissible" doses and dose rates for present and future use the background dose rate must be considered and compared with radiation dose-rates known to be harmful

The background dose is small compared with doses known to produce acute radiation effects, and it is likely that genetic and long-term carcinogenic effects are the main considerations In this context, the background dose rate to gonads of 0 1 rad per year or 3 rad in a generation of 30 years should be compared with the radiation dose-rate required to double the spontaneous human mutation rate This dose is uncertain, because the radiosensitivity of human genes is unknown and variable but the most recent estimate that can be quoted is that of Muller which suggests that the 'doubling dose' is unlikely to be more than 10 times this background dose

The soft tissue background dose-rate in bone is estimated at 0 12 rad per year or about 6 rad in 50 years This should be compared with the dose rate in people with small accidentally acquired radium burdens who show detectable radiographic bone changes, and where the dose rate is about 2000 times the background dose rate

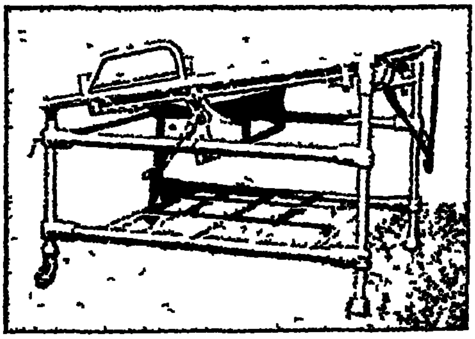
A similar comparison, assuming a normal atmospheric radon content of 3×10^{-13} curie per litre, of the background dose to lungs with the radiation doses causally associated with cancer in soft tissue gives a value 100–1000 times lower for background dose This background dose of 15 rad in 50 years (i e, three times the gonad dose) is probably 10,000 times less than the lung dosages of the Joachimstal uranium miners, in whom the incidence of lung cancer was so high

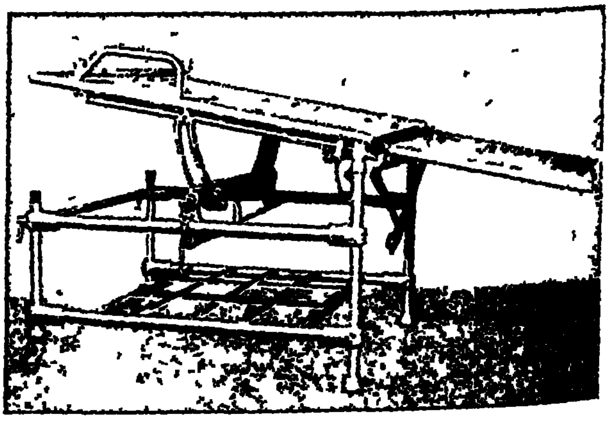
---

New Inventions

MODIFIED "OXFORD" LABOUR-WARD BED

SAFETY in unprepared cases needing a general anæsthetic depends somewhat on the ability of the anæsthetist to posture the patient quickly Either a head-down or a foot-down position may be desirable A head-down position will help to prevent aspiration into the lungs should vomiting occur, while a foot-down position may prevent reflux from the œsophagus (or stomach in certain circumstances) before intubation with a cuffed endotracheal tube during application of a muscle relaxant technique





In hospital obstetrical practice there are no reasons why special anæsthetic techniques for emergency general surgery should not be used in the labour ward, if they are to the patient's advantage[1] With this in mind the well-known "Oxford" labour-ward bed has been modified so that it can be quickly tilted into either a head-down or a foot-down position (see figures) The bed can be tilted 20° in either direction in three seconds This bed has now been in use at St Thomas's Hospital for just over a year and has proved equally satisfactory to midwives obstetricians, anæsthetists, and patients It is made by Hoskins & Sewell Ltd, Bordesley Birmingham, 12

BARBITURATE COMA WITH HYPOTHERMIA

D W Eason
M B St And

F I Macnaughton
M B Edin

LATE HOUSE OFFICERS ARBROATH INFIRMARY

Various methods have been used in the past for treating barbiturate coma Cerebral stimulants in the form of amphetamine derivatives and picrotoxin appear to have little effect when coma is deep, and purely supportive measures have recently tended to take the place of these drugs (Locket and Angus 1952) More recently two new drugs, bemegride and amiphenazole, the latter a respiratory stimulant and both barbiturate antagonists, have been introduced

An opportunity for comparing the effectiveness of these methods of treatment arose when a case presented in a small country hospital where the new drugs were not immediately available and treatment in the first instance was with picrotoxin, methedrine, and supportive measures Later, with persistent coma, treatment with bemegride and amiphenazole was given Further interest is added to the case by the complicating factors of exposure and hypothermia

Case-report

A married woman, aged 35 and weighing 105 lb , disappeared from her home on the morning of Oct 15, 1955, and twenty six hours later was found lying below the cliffs on the sea shore, apparently moribund She was dry but lightly clad (light coat, cotton house coat, cotton underwear, shoes, and stockings) The maximal and minimal environmental temperatures during the night of her exposure were 58°F and 45°F respectively Investigations showed that she had taken at least 21 ' Carbrital ' capsules, representing at least gr 31½ of soluble pentobarbitone and gr 84 of carbromal In addition she had probably taken phenobarbitone and aspirin

On admission to hospital at 10 45 A M on Oct 16 she was an ashen grey colour, and her whole body was cold She was pulseless, and her blood pressure was not recordable Faint heart sounds were present at the rate of 25 a minute with much prolonged systole showing by the spacing of the heart sounds Her respirations were shallow and irregular, from 1 to 3 a minute All her reflexes were absent and her pupils dilated A small amount of salicylate was detected in her urine There was no evidence of trauma

Treatment —An endotracheal tube was passed, through which oxygen with 10% carbon dioxide was administered mechanically with a Boyle s apparatus After fifteen minutes, respiration having become regular, the concentration of carbon dioxide was reduced to 5% Warmth was applied and later, a heat cage at its lowest setting was used intermittently The stomach was washed out, with a negative result Picrotoxin was given intravenously in 6 mg doses until 102 mg had been given It was then discontinued because little progress had been made (see figure) Methedrine was given intravenously in 15 mg doses to maintain the systolic blood pressure at 100 mm Hg Later, 30 mg was added to 1 pint of intravenous fluid on two occasions Continuous intravenous infusions were given, alternately of physiological saline solution and of dextrose , the solutions were warmed to approximately the patient's body temperature Her trachea and bronchi were cleared by suction every thirty minutes , on each occasion 5–15 ml of brown offensive secretions was aspirated Intramuscular penicillin 1,000,000 units was given, followed by 500 000 units eight hourly A catheter was passed six-hourly during coma, with little result initially Intramuscular mersalyl 2 ml was given to increase the excretion of barbiturate

Progress —After fifteen minutes' administration of 10% carbon dioxide in oxygen respiration became regular at a rate of 10 a minute Forty five minutes after admission a faint radial pulse was detectable and the heart rate had increased to 35 a minute The circulation improved over the next forty-five minutes, the pulse rate rising to 50 and the blood-pressure, which was very labile, to 70/40 mm Hg Pulse and blood pressure showed further improvement over the next two hours Six hours after admission, warmth having been applied throughout this period a thermometer graduated to a sufficiently low temperature became available Oral and axillary temperatures of 84 2°F were recorded Thereafter the axillary temperature rose steadily by about 2°F an hour for the next five hours, and then more slowly until it became normal eighteen hours after admission With restoration and maintenance of peripheral circulation and respiration the patient's colour and general condition improved but all her reflexes were still absent four hours after admission Her pupils did however, gradually decrease in size and eight hours after admission, reacted to light, and a corneal reflex was elicited Three hours later a feeble swallowing reflex was present When carbon dioxide and oxygen were temporarily withheld, the respirations diminished in depth and then in frequency , and the pupils dilated, with suppression of reaction to light and of the corneal reflex These changes also took place when 100% oxygen was administered for more than five minutes The interval during which the patient s respira-

commode is still a practical possibility—" the worst enemy of patient morale is the bedpan "

This is a useful, short, practical book It must be one of the few medical textbooks to be enlivened by drawings from the pen of as great an artist as the late Raoul Dufty

Éléments d'immunologie générale

P GASTINEL, professeur a la Faculte de Medecine de Paris,
R FASQUELLE, agrege de bacteriologie a la Faculte,
P BARBIER, chef de travaux de bacteriologie a la Faculte
Paris Masson 1955 Pp 335 Fr 2000

THE authors' aim is to cover the syllabus of French diplomas in immunoserology and to give an introduction to research-workers The treatment is rather uneven and it is not clear what knowledge is assumed in the reader For example, a few lines are devoted to the elementary chemistry and physics of amino-acids and proteins This is superfluous for those who have reached 2nd M B standard and inadequate for those who have not The development of ideas of immunity does not seem suitable for those unfamiliar with the subject, and the information about special aspects of immunology is at the same time too detailed for elementary students requiring a general survey, yet too fragmentary for the advanced worker

The Lacrimal System

Clinical Application EVERETT R VEIRS, M D, professor of ophthalmology, University of Texas Postgraduate School of Medicine New York and London Grune & Stratton 1955 Pp 156 $7 50

As Dr Veirs points out in a preface, many papers have been published on various aspects of the lacrimal apparatus, but none has so far covered the entire field He has made this interesting and well-arranged monograph as comprehensive as possible and he has written at length and in detail about the clinical features, methods of investigation, and conservative and surgical treatments of disorders of the lacrimal system

The work is admirably illustrated by photographs and clear pen and wash drawings There is a useful bibliography at the end of each of the twelve chapters Dr J V Cassady contributed the chapter on developmental anatomy Several techniques of performing dacryocystorhinostomy by the intranasal route are excellently described

Perhaps after the description of Summerskill's polythene intubation of a dacryocystorhinostomy and of permanent intubation of the naso lacrimal duct, some comment should have been made about the failures and serious complications of these techniques In the full description of the dacryocystorhinostomy operation the author has omitted to mention that the bony fenestration in the lacrimal fossa may be achieved very well, and without damage, either to the nasal mucosa or the lacrimal sac, by using Traquair's elevator, Citelli's punch, and then Ferris Smith's nibblers There is also no reference to the value of Stryker's electric saw trephine

The book is well produced and will appeal not only to the eye surgeon but to the rhinologist and pædiatrician

The Pediatric Years

LOUIS SPEKTER, M D, director, bureau of maternal and child hygiene, Connecticut State Department of Health Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1955 Pp 734 90s

THE aim of this book is to provide an understanding of the child in health and sickness for those working with doctors in a pædiatric service It is written for the American worker and much of it reflects the views of that continent both in practice and education Comprehensive and up to date, it achieves the rare feat of making the pathology of children's diseases understandable to those without basic medical training

The British medical auxiliary will value highly the digest of children's diseases and the chapters on development hospital care and pædiatric procedures The chapters on the range and scope of the social services will appeal to those interested ls of solving social and medical problems in the non welfare State More might usefully have been said about parents, whose attitudes exert such a profound influence for good or ill, and to whom much of the advice in this book will be passed on

Few teachers of students, nurses, almoners, and other medical workers would not be glad of the help this book can give

Laboratory Control of Dairy Plant

J G DAVIS, D SC PH D, F R I C London Dairy Industries Ltd 1956 Pp 395

THE dairy industry is exceptional in the use which it makes of chemistry and bacteriology in its daily practice No other branch of the food trade is so " laboratory-minded " or offers so much responsibility to those with a scientific training Among these, few are better qualified to write this book than Dr Davis It is a working manual for manager and technician which covers all the details of day-to-day control without losing sight of the principles upon which these are based Nowadays the technicalities of the milk trade seldom trouble the medical officer of health but, when they do, it would be difficult to recommend a source of information so lucid so succinct, and so well indexed

Functional Otology

The Practice of Audiology MORRIS F HELLER, M D chief, audiology clinic, Mount Sinai Hospital, New York New York Springer London Interscience Publishers 1955 Pp 209 40s

IT is immediately clear to the reader that Dr Heller's experience in audiology is unusually broad He goes into considerable detail about the staff, equipment, and administration of an audiology centre and deals quite fully with all those important borderline aspects of his subject that are so often lacking or inadequate in a textbook of otolaryngology There is a useful chapter on " non organic deafness " and a helpful and timely description of the transistor hearing-aid Some discussion of the medical and surgical aspects of deafness would have been welcome, but nevertheless the book provides valuable supplementary reading to the otologist who has a particular interest in the problems of deafness

---

The Chemical Constitution of Natural Fats (3rd ed London Chapman & Hall 1956 Pp 664 95s)—With the present great interest in the physiology of fats and their possible roles in disease, the new edition of this standard work by Prof T P Hilditch, F R S, comes opportunely It gives the details of the chemical constitution of both animal and vegetable fats from a great variety of species set out clearly but with encyclopædic thoroughness A feature of the book is the separate indexes for individual fats and waxes, individual fatty acids, individual glycerides and of plant families There is also a valuable chapter on analytical methods The only criticism is that Professor Hilditch has confined himself strictly to the letter of his title and so there is no reference to margarines and other processed fats which feature in human diet The information collected in this book is nowhere else so readily available and will continue to be of great value to biologists and medical research workers

The Back and its Disk Syndromes (2nd ed Philadelphia Lea & Febiger London Henry Kimpton 1955 Pp 942 £6 15s)—The foundation of this book is the close personal experience with over 40 000 'back cases' This seems a prodigious experience, and if Prof Philip Lewin has applied to each patient all the clinical tests he describes it is hard to understand how he has managed to find time to write similar books on the foot and on the knee Hardly anything has been left out, and the effort to include everything has made an indigestible book The familiar is intermingled with the erudite, and the inexperienced reader will find difficulty in gleaning an orderly scheme of treatment for any individual case The diagrams are clear and helpful and the general production of high quality Many of the author's pithy remarks are admirably suited to stick in the student's memory The book is a further monument to Dr Lewin's industry and learning

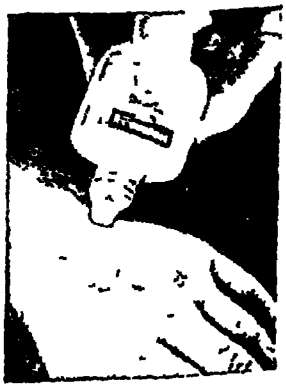
Spreading smooth and even . . .



Smoothly, thinly and painlessly Ef-Cortelan Skin Lotion (hydrocortisone Glaxo) spreads over tender surfaces Swiftly, safely, effectively—sometimes in a few hours—it suppresses inflammation, exudation and allergic skin reactions

A little goes a long way

Most conditions are adequately controlled by the 0.5% Ef-Cortelan Lotion and, because it has superior spreading and penetrating qualities and brings hydrocortisone into more intimate contact with the tissues, the lower strength is as effective as a 1% ointment. This, and the fact that only a little of the lotion is used, offers appreciable economic advantages Ef-Cortelan Lotion is especially suitable for extensive, weeping surfaces and for application to the scalp

GLAXO EF-CORTELAN SKIN LOTION

(0.5% and 1% hydrocortisone alcohol in water-miscible base) in 20 cc squeeze bottles

ALSO FROM THE GLAXO CORTISONE RANGE EF-CORTELAN SKIN OINTMENT NO 1 (1% and 2½% hydrocortisone acetate in *non-greasy* base), EF-CORTELAN SKIN OINTMENT NO 2 (1% and 2½% hydrocortisone acetate in *greasy* base) Both in 5 g and 15 g tubes, 30 g jars

GLAXO LABORATORIES LTD , GREENFORD, MIDDLESEX BYRon 3434 days later, on Dec. 22, the child was discharged home still slightly ataxic but reacting normally to his parents and feeding well.

All the urine was collected from the time of diagnosis—i.e., thirty-six hours after the onset of coma—for seventy-two hours. In the first twenty-four hour specimen 56 mg. of phenobarbitone was found; in the second 13 mg.; and in the third 10 mg. Metabolites of the drug were not detected.

Follow-up.—Seen on Jan. 2, 1956, the child was well; in fact his parents complained that he was sleeping badly.

Discussion

This child received a large dose of phenobarbitone (about gr. 55 in divided doses in thirty-six hours) and was in coma for at least thirty-six hours before treatment was begun. Since his respiration did not become depressed, he might well have recovered without active treatment.

The fact that he was fat may have been to his advantage. It is known that some of the short-acting barbiturates—e.g., thiopentone—are absorbed from the blood-stream by fatty tissue (Goodman and Gilman 1955). The fact that respiration was not affected in this case suggests that a similar mechanism may apply to phenobarbitone.

The small amounts of phenobarbitone found in the urine can be explained by the lapse of time before collection was begun and the amount which must have been metabolised (Goodman and Gilman 1955).

Unless respiration is depressed, the use of amiphenazole as well as bemegride seems unnecessary, although it has been recommended (Shulman et al. 1955).

Bemegride does not appear to be toxic. The chief danger in its use seems to lie in failing to realise that it may have to be given for a long time. The patient's condition is liable to regress if the dose is reduced prematurely. This was well shown in the present case, where bemegride had to be given for eighty hours. For this reason it seems more sensible to mix it with the intravenous transfusion fluid in the bottle rather than to inject it intermittently.

Summary

A case of phenobarbitone poisoning in a child aged 14 months is reported. Phenobarbitone had been administered for thirty-six hours by mistake for succinylsulphathiazole.

On admission the child was deeply comatose, but his respiration and circulation were not depressed.

He was treated successfully with 2827 mg. of bemegride mixed with a convenient intravenous transfusion fluid, given continuously for eighty hours.

We wish to thank Dr. T. Stapleton, who was in charge of the case, for advice and encouragement; Prof. A. Neuberger for help in the diagnosis and for the chemical analyses; and Dr. Keith Mant, Dr. T. A. B. Harris, and Dr. T. E. Oppé for advice.

The association's spring meeting was held at Gleneagles on May 3–5, under the presidency of Mr. Philip Wiles.

Conservative Treatment of Spinal Tuberculosis

Mr. J. P. Jackson (Harlow Wood) discussed 89 cases of spinal tuberculosis, reviewed not less than two years after treatment, which had consisted of immobilisation on a frame or plaster bed and streptomycin 1 g. and *p*-aminosalicylic acid 18 g. daily for ninety days. 3 patients had died, all from meningeal or genito-urinary infection. Amyloid disease and sepsis were no longer problems, and sinuses closed more readily, although five had persisted and one new sinus had developed under treatment. Posterior fusion by tibial grafts was usually undertaken when the lesion was quiescent, and of these 36% proceeded to anterior fusion also; anterior fusion had occurred in 46% of cases which had not been operated on but gave no certain guard against relapse, which ensued in 11% of such cases. The relapse rate after surgery was, however, only half that where no operative fusion had been performed. Abscesses were not opened routinely, but it was found that only 24% of those with persistent abscesses proceeded to bony fusion. Mr. Jackson concluded that general treatment was still necessary; conservative treatment with three months' chemotherapy gave 21% unsatisfactory results, but total duration of treatment was shorter and mortality was reduced. Posterior grafting was well worth while.

Mr. Robert Roaf (Liverpool) remarked that chemotherapy is now given usually for nine to twelve months, and that we have learnt how fallacious the interpretation of radiographs can be in assessing quiescence.

V-nail Fixation for Fractured Neck of Femur

Mr. A. W. Fowler (Bridgend) recommended V-nail fixation for trochanteric and basal fractures of the neck of the femur. This was a modification of the "low nail" operation described by Brittain in 1942. A V-nail (actually a clover-leaf Küntscher nail with half of the lateral leaves shaved down) provided fixation based on three solid points—the dense bone of the head, the upper end of the medial cortex of the shaft, and the outer cortex at the point of penetration. He permitted weight-bearing after eight weeks, and earlier in stable fractures. This admittedly experimental method was mechanically sound and cheaper and more efficient than pin or bladeplate, and it permitted telescoping when necessary, but not coxa vara.

Mr. G. K. McKee (Norwich) had had similar favourable experience of the procedure, but remarked that some apparently pertrochanteric fractures were really subtrochanteric posteriorly, so a nail might split the cortex in this region. He therefore preferred to add to a vertical nail a slotted plate which would allow some telescoping.

Mr. Roland Barnes (Glasgow) did not think that this method was adequate for the unstable type of fracture because the comminution of the inner cortex would preclude stability and permit varus deformity with danger of the nail breaking through the head as in other methods.

Internal Fixation for Bennett's Fractures

Mr. F. C. Badger (Birmingham) described his method of treating Bennett's fractures, whereby through a dorsal incision the fragment was reduced and fixed by a small screw passed through the base of the shaft. No plaster was necessary. The patients were off work on average for three weeks. In 13 out of 17 cases the results had been good, the failures resulting either from the use of too short a screw with later redisplacement of the fragment, or from a badly placed screw.

Mr. O. J. Vaughan-Jackson said that he used a small pin and a mid-lateral approach; in 2 cases the small fragment had been found turned over so that the articular cartilage was apposed to cancellous bone on the major fragment.

Congenital Dislocation of Hip

Mr. J. C. Scott (Oxford) reported the interim results of 75 cases of congenital dislocation of the hip treated at Oxford since 1949, under the régime devised by Mr. E. W. Somerville and himself. The cases were treated within what he called the "critical period"—from the beginning of weight-bearing to the age of 4. The method consisted in (1) gradual reduction by traction on a special frame, (2) operative removal of the limbus where this was shown by the arthrogram to be inturned, and (3) rotation osteotomy to correct anteversion when required. He believed that the dislocation was first anterior and later became superior and then posterior for the head to lie on the dorsum ilii. He thought that it was usually the lesser trochanter that pushed in the limbus; the secondary reduction in circulation was responsible for the smallness of the epiphysial head and cases of later osteochondritis. The a satisfactory rise in hæmoglobin. It is for this reason that we wonder whether it would not be better to have the second blood examination earlier—say, between the 28th and 32nd weeks. If patients with anæmia of pregnancy fail to respond properly to parenteral iron, they have almost certainly a megaloblastic anæmia. Israëls and Da Cunha[7] stated that the only certain method of establishing the diagnosis was by examination of the bone-marrow, and they pointed out that the investigator must look for transitional megaloblasts and giant metamyelocytes, and not rely on finding classically developed megaloblasts. These findings have been confirmed by Lowenstein et al.,[8] working in Canada, and by many others. The Canadian group found that there is nearly always an iron-deficiency anæmia as well, and that the response to therapy is often slower than that in addisonian pernicious anæmia. They found that 4 of their 18 patients responded to treatment with vitamin B_{12}, but most reports from temperate climates state that patients are resistant to B_{12} and the proper treatment is folic acid (15–20 mg. daily, orally or parenterally).

The more controversial part of Edgar and Rice's recommendations is that iron should be given to all pregnant women, so that all of them go through pregnancy with a hæmoglobin level of 90% or so. Fisher and Biggs[9] gave iron supplements to 104 mothers and all but 12 had hæmoglobin levels of 90% at term, and there is little doubt, as Jennison and Ellis[10] pointed out, that by using parenteral iron most of the non-responders could have their hæmoglobin levels similarly raised at term. What is not clear is whether it is really beneficial for the mother to have a higher hæmoglobin at term than in the normal course of events. We have seen that the red-cell mass is not decreased in a normal pregnancy; presumably (though we have no data) if the hæmoglobin level at term is 90% instead of 75% of normal, the red-cell mass will be notably increased. Is this helpful? Fisher and Biggs promised their patients that they would be "fighting fit" for labour and for the duties of the puerperium, but all they tell us is that they "gathered the impression" that the patients were more energetic. There is now no doubt that anæmia of pregnancy can be prevented if the patients will attend their antenatal clinics or see their own doctors in time, and if anæmia develops it can be efficiently treated. But we should not lose sight of the other factors in nutrition: iron is only one factor and the ideal of "a quart of milk, 4 oz. of meat, and one egg" daily, in addition to any iron supplement, should still be aimed at.

Upper Respiratory Virus Infections

Virus infections of the upper respiratory tract probably form the largest group of illnesses encountered in general medical practice. When the common colds and virus influenzas are subtracted from the total there remain a large number of infections which are variously diagnosed as pharyngitis, laryngitis, tracheitis, bronchitis, &c.—that is, names which describe the site at which symptoms and signs are most prominent. It is well known, however,[1] that different viruses can produce illnesses which are clinically indistinguishable, and conversely that a single agent, the influenza virus, may produce a very variable clinical picture in different individuals. Laboratory research on this subject is therefore very welcome, and an excellent review[2] of recent papers has come from Dingle and Feller.

We are learning rapidly about the part played by a new group of viruses in infections of the upper respiratory tract, but, surprisingly, one of the difficulties that plagues everyone who writes or talks about these viruses is what to call them. Rowe et al.[3] described the first isolation of the new viruses—from adenoidal tissue removed at operation from children. Since these viruses caused degeneration of adenoidal cells in tissue culture they were called adenoidal degeneration (AD) viruses. Shortly afterwards Hilleman and Werner[4] recovered a serologically related agent from an outbreak of upper respiratory disease in a military camp, and called their virus RI-67. Huebner and his co-workers[5] have now isolated as many as 11 distinct immunological types of virus from man, of which type 3 has been related to outbreaks of non-bacterial pharyngitis,[6] types 4 (i.e., RI-67 virus) and 7 have been related to outbreaks of acute respiratory disease in recruits,[2] and type 8 may be implicated in the ætiology of epidemic keratoconjunctivitis.[5 7] Huebner et al.[6] proposed to call the group of viruses the adenoidal-pharyngeal-conjunctival (A.P.C.) viruses, but Dingle and Feller[2] prefer to call them the viruses of acute respiratory disease (A.R.D. viruses), and Hilleman et al. describe them as the RI group of viruses. At a recent meeting one virologist suggested that to commemorate the work of Huebner, Dingle, and Hilleman, the group should be called the Hudihi or Hidihu viruses—a suggestion which could hardly increase the present state of confusion. Since we have earlier used the name A.P.C.,[8] we shall retain it for the time being.

Types 4 and 7 of the A.P.C. viruses have now been clearly associated with what Stuart-Harris et al.[1] called "febrile catarrh" and what was subsequently called acute respiratory disease (A.R.D.).[9] This is an acute respiratory infection which characteristically occurs in epidemics among military recruits but not in seasoned men. Andrews et al.[9a] found little evidence of A.P.C. infection in 10 R.A.F. stations which did not receive recruits. The illness is an acute, febrile, influenza-like infection in which constitutional upset is usually less prominent and sore throat, hoarseness, and cough are more noticeable than in influenza. Among the physical signs injection of the pharynx and slight enlargement of the cervical lymph glands are common. There are a number of mysteries in the epidemiology of this infection. Its association with recruits suggests that it produces much more immunity than does virus influenza, which attacks recruits and seasoned men

days later, on Dec 22, the child was discharged home still slightly ataxic but reacting normally to his parents and feeding well

All the urine was collected from the time of diagnosis—i e , thirty six hours after the onset of coma—for seventy-two hours In the first twenty four hour specimen 56 mg of phenobarbitone was found, in the second 13 mg , and in the third 10 mg Metabolites of the drug were not detected

Follow up—Seen on Jan 2 1956, the child was well, in fact his parents complained that he was sleeping badly

Discussion

This child received a large dose of phenobarbitone (about gr 55 in divided doses in thirty-six hours) and was in coma for at least thirty-six hours before treatment was begun Since his respiration did not become depressed, he might well have recovered without active treatment

The fact that he was fat may have been to his advantage It is known that some of the short-acting barbiturates—e g , thiopentone—are absorbed from the blood stream by fatty tissue (Goodman and Gilman 1955) The fact that respiration was not affected in this case suggests that a similar mechanism may apply to phenobarbitone

The small amounts of phenobarbitone found in the urine can be explained by the lapse of time before collection was begun and the amount which must have been metabolised (Goodman and Gilman 1955)

Unless respiration is depressed, the use of amiphenazole as well as bemegride seems unnecessary although it has been recommended (Shulman et al 1955)

Bemegride does not appear to be toxic The chief danger in its use seems to lie in failing to realise that it may have to be given for a long time The patient's condition is liable to regress if the dose is reduced prematurely This was well shown in the present case, where bemegride had to be given for eighty hours For this reason it seems more sensible to mix it with the intravenous transfusion fluid in the bottle rather than to inject it intermittently

Summary

A case of phenobarbitone poisoning in a child aged 14 months is reported Phenobarbitone had been administered for thirty six hours by mistake for succinylsulphathiazole

On admission the child was deeply comatose, but his respiration and circulation were not depressed

He was treated successfully with 2827 mg of bemegride, mixed with a convenient intravenous transfusion fluid given continuously for eighty hours

We wish to thank Dr T Stapleton, who was in charge of the case, for advice and encouragement, Prof A Neuberger for help in the diagnosis and for the chemical analyses and Dr Keith Mant, Dr T A B Harris, and Dr T E Oppe for advice

In the same year DALTON [18] and MADDER [19] gave the method a trial with equally gratifying results, and BLAND SUTTON followed WEBB-JOHNSON immediately.

Whatever the reason for the leaps and jumps by which surgery advances (surgical fashion being no more suited to reasoned analysis than the changing fashion in hats and politics), they prove at least the need for periodical re-examination of the practices on which we rely. The no-dressing technique merits re-examination, not only because some of the arguments in its favour may be even more valid today than they were in the past, but because the success recorded by WEBB-JOHNSON and others casts unexpected light on the uncommonness of wound infection in clean surgical incisions forty-four years ago. Though no comparable figures are available, its prevalence is almost certainly much higher today.

FRANK MELENEY [20] says that "if we were to ask the average surgeon how often his clean wounds become infected, he would probably answer, 'Very *seldom, not* once in a hundred times,' or 'I haven't had an infection for years.' In actual fact, the number will vary from 5 to 20 per cent, or more, of all clean cases. Of those 1 to 5 per cent will be serious, resulting in pain, fever, suppuration, weakness of the wound, disruption or hernia, prolonged hospitalisation and occasionally death." (One must include here fatal complications of antibiotic treatment.) "The others may be called trivial, but they are annoying to the patient and usually delay his departure from the hospital. In the average case of infection the patient must remain in hospital just twice as long as the patient in whom infection does not occur."

If indeed more operation wounds become infected today than forty years ago, the explanation is not far to seek. In 1912 wound infection meant a major disaster: at best it delayed the patient's convalescence by weeks or months, at worst it killed him. Today, on the other hand, if sterile technique falls short of the highest standard, there is a strong temptation to say "What does it matter? A few pricks—or the latest fashionable 'mycin'—will take care of that." It all sounds very simple, yet LOWBURY [21] was right when he remarked that the "dilemma of hospital infection has been complicated rather than solved by chemotherapy."

In their investigation in a thoracic surgical unit in the North of England, BLOWERS et al.[22] were impressed by the fact that, far from diminishing the incidence of wound-infection, the routine use of "penicillin-cover" merely increased the number of resistant organisms, and thus made the management of cases more difficult. Furthermore, they found that most of the wound-infections originated in the theatre at the time of the operation—the chief reasons for infection being inefficient ventilation, the use of blankets in the theatre, and excessive movement by the staff.

It should be unnecessary in 1956 to point to the advantages of asepsis over antisepsis. All the minutiæ of its technique have been worked out over the past fifty years—the autoclaving of instruments, the scrubbing of hands, the masking of noses, the preparation of operation fields, the avoidance of contamination by air currents, the use of silk a
nylon, the gentle handling of tissues, the car
hæmostasis. Nevertheless, at a time when all th
precautions should bring the incidence of wou
infection in clean surgical fields to less than 1-2
antisepsis—euphemistically labelled "prophylac
antibiotic cover"—is creeping back into our practi

PROGNOSIS OF CARDIOVASCULAR SYPHILIS

IT has never been conclusively proved that speci
treatment prolongs life in cardiovascular syphilis. Twent
years ago Padget and Moore [24] claimed that the mortali
of syphilitic aneurysm and aortic incompetence w
halved by arsenical treatment, but they also foun
that the average duration of life in those who died w
not significantly prolonged. Grant's figures [25] from th
country, when re-examined by Moore [26] in 1949, reveal
the same phenomenon. There are several reasons wh
different expressions of the same result may lead t
conflicting conclusions. In the first place, it is only fu
to compare the duration of life when all the patient
are dead. This may mean waiting fifteen or twenty yea
to complete a follow-up study, and few have sufficien
patience for this; yet if the average duration of lif
is calculated before all the patients are dead the figur
will be weighted by those who die early. Another reaso
lies in the exceptional difficulty of arranging a properl
controlled investigation in an increasingly rare disease
which exhibits wide variations of age-incidence, dura
tion, and severity. Moreover, it is a disease which i
subject to complications, such as neurosyphilis, where
specific treatment is undoubtedly effective and cannot
be withheld; this prevents the random allocation of
patients into treated and control groups which is the
essence of a sound therapeutic trial.

An interesting commentary on these problems ha
been provided in the past year by two notable studies
of arsenical treatment in cardiovascular syphilis. In
Chicago, O'Brien and his colleagues [27] found no difference
in mortality between those who received "adequate
treatment (more than 20 arsenical injections) and those
who did not. On the other hand, Grimble,[28] in a careful
study of fatal cases treated at Guy's Hospital between
1923 and 1944, reached the opposite conclusion. He
claimed that the average duration of life in aneurysm
and aortic incompetence was approximately doubled
by arsenical treatment, increasing *from two to four*
and a half years.

Mr **Robert Roaf** (Liverpool) remarked that chemotherapy is now given usually for nine to twelve months, and that we have learnt how fallacious the interpretation of radiographs can be in assessing quiescence

V-nail Fixation for Fractured Neck of Femur

Mr **A W Fowler** (Bridgend) recommended V nail fixation for trochanteric and basal fractures of the neck of the femur This was a modification of the "low nail" operation described by Brittain in 1942 A V-nail (actually a clover leaf Kuntscher nail with half of the lateral leaves shaved down) provided fixation based on three solid points—the dense bone of the head, the upper end of the medial cortex of the shaft, and the outer cortex at the point of penetration He permitted weight bearing after eight weeks, and earlier in stable fractures This admittedly experimental method was mechanically sound and cheaper and more efficient than pin or bladeplate, and it permitted telescoping when necessary, but not coxa vara

Mr **G K McKee** (Norwich) had had similar favourable experience of the procedure, but remarked that some apparently pertrochanteric fractures were really subtrochanteric posteriorly, so a nail might split the cortex in this region He therefore preferred to add to a vertical nail a slotted plate which would allow some telescoping

Mr **Roland Barnes** (Glasgow) did not think that this method was adequate for the unstable type of fracture because the comminution of the inner cortex would preclude stability and permit varus deformity with danger of the nail breaking through the head as in other methods

Internal Fixation for Bennett's Fractures

Mr **F C Badger** (Birmingham) described his method of treating Bennett's fractures, whereby through a dorsal incision the fragment was reduced and fixed by a small screw passed through the base of the shaft No plaster was necessary The patients were off work on average for three weeks In 13 out of 17 cases the results had been good, the failures resulting either from the use of too short a screw with later redisplacement of the fragment, or from a badly placed screw

Mr **O J Vaughan Jackson** said that he used a small pin and a mid lateral approach, in 2 cases the small fragment had been found turned over so that the articular cartilage was apposed to cancellous bone on the major fragment

Congenital Dislocation of Hip

Mr **J C Scott** (Oxford) reported the interim results of 75 cases of congenital dislocation of the hip treated at Oxford since 1949, under the regime devised by Mr E W Somerville and himself The cases were treated within what he called the 'critical period'—from the beginning of weight bearing to the age of 4 The method consisted in (1) gradual reduction by traction on a special frame, (2) operative removal of the limbus where this was shown by the arthrogram to be in turned, and (3) rotation osteotomy to correct anteversion when required He believed that the dislocation was first anterior and later became superior and then posterior for the head to lie on the dorsum ilii He thought that it was usually the lesser trochanter that pushed in the limbus, the secondary reduction in circulation was responsible for the smallness of the epiphysial head and cases of later osteochondritis The well as the liver changes. In at least one instance, there was also an acute hæmorrhagic pancreatitis. On the basis of these findings, Ober and Le Compte see a similarity between the condition in man and the lesions produced in rats by the feeding of ethionine, an unnatural amino acid that interferes with the proper metabolism of methionine.[4] Since the effects of ethionine can be neutralised by giving methionine there may be some indication for the use of methionine in the treatment of these patients. Aspiration biopsy of the liver, however, seems to be the only way to make the diagnosis before it is too late.

FUNGUS INFECTIONS OF BONE

THE relative importance of diseases caused by pathogenic fungi has increased as the power of chemotherapy has subdued the bacteria. Lesions of bone are by no means rare in many fungus infections, and they are sometimes responsible for the first signs and symptoms of illness. A recent paper by Toone and Kelly[5] notes, for example, 8 instances of bone involvement among 25 cases of systemic fungal infection seen over a period of five years at two general hospitals in Richmond, Virginia. 5 of the 8 cases were examples of blastomycosis and 1 coccidioidomycosis—two conditions rarely if ever seen outside the American continent. The 2 remaining infections were cryptococcosis (torulosis)—a condition well recognised all over the world and occasionally reported in this country.

There have been many American reports of bone lesions in these infections. Potter,[6] in 1910, and Stober,[7] in 1914, were among the earliest to describe bone changes. In systemic blastomycosis multiple granulomatous lesions are associated with local bone destruction and definite periosteal reaction. The bones are said to be involved in as many as 60% of fatal cases,[8] and the lesions are often connected with discharging sinuses. Carter[9] later described rather similar disseminated bony lesions in coccidioidomycosis, and Collins[10] has noted 17 examples of the same type of bony involvement in 200 published cases of torulosis. Bony involvement as the first sign has even been recorded in histoplasmosis,[11] which is occasionally seen in this country and is usually marked by fever, emaciation, anæmia, and widely disseminated lesions.

Actinomycosis is, of course, the commonest systemic fungal infection in this country,[12] and bones are often involved. Bones are usually infected by local extension from soft-tissue lesions: thus the mandible may be attacked in cervicofacial actinomycosis and the spine in the abdominal form of the disease. This mode of spread is in contrast to the blood-stream dissemination which is responsible for bone lesions in the other fungus infections. Infection can also spread directly to bone in maduromycosis (Madura foot) in which a variety of different fungi may be present.

In all these conditions, diagnosis depends ultimately on recovering organisms from pus or other material. Special bacteriological techniques are often needed, and they should be used in the investigation of material from all cases of obscure infection, whether or not fungal cells have been identified on direct microscopic examination. In some, but not all of these infections, fungal elements can be identified in histological sections, and in recent years the periodic-acid Schiff staining technique has been found effective.[13-15] Complement-fixing antibodies or hypersensitivity to fungal vaccine are sometimes a help in diagnosis at certain stages of infection.

It is clear that we should be more aware of fungal infections even in a part of the world where relatively few are endemic. One of the best introductions to the subject for the general reader is the brief monograph[16] by Conant and his colleagues, of Duke University, North Carolina. Added importance has recently been given to prompt and accurate diagnosis by encouraging therapeutic results[17-19] with the aromatic diamidines, particularly 2-hydroxystilbamidine, in blastomycosis, actinomycosis, and cryptococcosis, but no effective treatment has yet been found for coccidioidomycosis and histoplasmosis or for cryptococcosis involving the central nervous system.

CHILD MENTAL WELFARE

MUCH mental illness can be attributed, in part at least, to disturbances in parent-child relations in the earliest years of childhood. In the past, child-guidance clinics have been regarded as preventive services, but they have never in fact been this, since few children come to these clinics until several years after their troubles begin. The foundations of the parent-child relationship are laid in the antenatal period and during the first few months of the child's life. At this time the parents are facing new anxieties, and their emotional attitudes are often changing. They are then most accessible to help, and quite simple measures may tip the balance in the right direction. Early action necessarily depends upon early recognition, and here the staffs of antenatal and child-welfare clinics have a unique opportunity. But this help can succeed only if the clinic staffs are encouraged to take an interest in mental-health problems and concern themselves actively with preventive mental-health work. There have lately been cheering signs that more is being done in this direction.[20]

The recent report of the committee on maladjusted children[21] recommended that the staffs of child-guidance clinics should cooperate more closely with those of the welfare centres. This is not a new idea: several child-guidance clinics in London have been established in child-welfare centres for eight or nine years, and in 1952 the first comprehensive health centre was opened by the London County Council at Woodberry Down. It is encouraging, however, to read of further developments. Mackenzie[22] has lately discussed a scheme for "voluntary training" of welfare-centre staff, who are interested in this work. Since 1953 weekly case conferences have been held at a child-welfare centre. At first they were attended by a welfare-centre doctor and health visitor and by a psychiatrist and a psychiatric social worker. The team was later expanded to include 3 welfare-centre doctors and 2 health visitors. Patients did not attend the conferences. No rigid scheme was followed, but the discussion was generally directed towards clinical problems, the initiative being left with the welfare team. Mackenzie attaches great importance to the presence at the discussion of the welfare-centre doctor and the health visitor concerned with a particular patient, and much of the success of the scheme has sprung from the different approaches of the various members of the team. New

days later, on Dec 22, the child was discharged home still slightly ataxic but reacting normally to his parents and feeding well

All the urine was collected from the time of diagnosis—i e, thirty six hours after the onset of coma—for seventy-two hours In the first twenty-four hour specimen 56 mg of phenobarbitone was found, in the second 13 mg, and in the third 10 mg Metabolites of the drug were not detected

Follow-up —Seen on Jan 2 1956, the child was well, in fact his parents complained that he was sleeping badly

Discussion

This child received a large dose of phenobarbitone (about gr 55 in divided doses in thirty six hours) and was in coma for at least thirty-six hours before treatment was begun Since his respiration did not become depressed, he might well have recovered without active treatment

The fact that he was fat may have been to his advantage It is known that some of the short acting barbiturates—e g, thiopentone—are absorbed from the blood stream by fatty tissue (Goodman and Gilman 1955) The fact that respiration was not affected in this case suggests that a similar mechanism may apply to phenobarbitone

The small amounts of phenobarbitone found in the urine can be explained by the lapse of time before collection was begun and the amount which must have been metabolised (Goodman and Gilman 1955)

Unless respiration is depressed, the use of amiphenazole as well as bemegride seems unnecessary, although it has been recommended (Shulman et al 1955)

Bemegride does not appear to be toxic The chief danger in its use seems to lie in failing to realise that it may have to be given for a long time The patient's condition is liable to regress if the dose is reduced prematurely This was well shown in the present case, where bemegride had to be given for eighty hours For this reason it seems more sensible to mix it with the intravenous transfusion fluid in the bottle rather than to inject it intermittently

Summary

A case of phenobarbitone poisoning in a child aged 14 months is reported Phenobarbitone had been administered for thirty six hours by mistake for succinylsulphathiazole

On admission the child was deeply comatose, but his respiration and circulation were not depressed

He was treated successfully with 2827 mg of bemegride, mixed with a convenient intravenous transfusion fluid, given continuously for eighty hours

We wish to thank Dr T Stapleton, who was in charge of the case, for advice and encouragement, Prof A Neuberger for help in the diagnosis and for the chemical analyses and Dr Keith Mant, Dr T A B Harris, and Dr T E Oppé for advice

Medical Societies

BRITISH ORTHOPÆDIC ASSOCIATION

THE association's spring meeting was held at Gleneagles on May 3–5, under the presidency of Mr PHILIP WILES

Conservative Treatment of Spinal Tuberculosis

Mr J P JACKSON (Harlow Wood) discussed 89 cases of spinal tuberculosis, reviewed not less than two years after treatment, which had consisted of immobilisation on a frame or plaster bed and streptomycin 1 g and *p* aminosalicylic acid 18 g daily for ninety days 3 patients had died, all from meningeal or genito urinary infection Amyloid disease and sepsis were no longer problems and sinuses closed more readily, although five had persisted and one new sinus had developed under treatment Posterior fusion by tibial grafts was usually undertaken when the lesion was quiescent, and of these 36% proceeded to anterior fusion also, anterior fusion had occurred in 46% of cases which had not been operated on but gave no certain guard against relapse, which ensued in 11% of such cases The relapse rate after surgery was, however, only half that where no operative fusion had been performed Abscesses were not opened routinely, but it was found that only 24% of those with persistent abscesses proceeded to bony fusion Mr Jackson concluded that general treatment was still necessary, conservative treatment with three months chemotherapy gave 21% unsatisfactory results but total duration of treatment was shorter and mortality was reduced Posterior grafting was well worth while

Mr ROBERT ROAF (Liverpool) remarked that chemotherapy is now given usually for nine to twelve months, and that we have learnt how fallacious the interpretation of radiographs can be in assessing quiescence

V-nail Fixation for Fractured Neck of Femur

Mr A W FOWLER (Bridgend) recommended V nail fixation for trochanteric and basal fractures of the neck of the femur This was a modification of the " low nail " operation described by Brittain in 1942 A V-nail (actually a clover leaf Kuntscher nail with half of the lateral leaves shaved down) provided fixation based on three solid points—the dense bone of the head the upper end of the medial cortex of the shaft, and the outer cortex at the point of penetration He permitted weight bearing after eight weeks, and earlier in stable fractures This admittedly experimental method was mechanically sound and cheaper and more efficient than pin or bladeplate, and it permitted telescoping when necessary but not coxa vara

Mr G K MCKEE (Norwich) had had similar favourable experience of the procedure, but remarked that some apparently pertrochanteric fractures were really subtrochanteric posteriorly, so a nail might split the cortex in this region He therefore preferred to add to a vertical nail a slotted plate which would allow some telescoping

Mr ROLAND BARNES (Glasgow) did not think that this method was adequate for the unstable type of fracture because the comminution of the inner cortex would preclude stability and permit varus deformity with danger of the nail breaking through the head as in other methods

BEDWETTING

PREVALENCE AMONG CHILDREN AGED 4-7 YEARS

J. M. BLOMFIELD
M.A. Oxfd
RESEARCH WORKER, POPULATION INVESTIGATION COMMITTEE

J. W. B. DOUGLAS
B.M. Oxfd
SENIOR LECTURER IN PUBLIC HEALTH AND SOCIAL MEDICINE IN THE UNIVERSITY OF EDINBURGH

THE importance of bedwetting as a public health problem is emphasised by Bransby, Blomfield, and Douglas (1955). We describe here more fully its prevalence in different groups of the population and discuss the extent to which it might be prevented or reduced by changes in environment or in upbringing.

Our data are derived from 5386 children born during the first week of March, 1946. These children were followed up by health visitors during the pre-school years, and on reaching school age were kept under observation both by school nurses and by school doctors. At present, when they are 10 years old, we are still in touch with 4351 children (92% of those who were enrolled in the 1946 survey and are still living in this country). They are fully representative of the whole population of children of their age.[1]

Questions about bedwetting were asked on three occasions by either health visitors or school nurses during home visits made when the survey children were aged 4¼, 6, and 7¾ years. At each visit the mothers were asked whether their child was wet by night and, if so, how often. On the second visit they were also asked whether he was wet by day. Information about methods used to cure the wet children was obtained when they were aged 6 and 7¾ years, and on the last visit the mothers were asked whether any of the sibs of the survey children had been bedwetters.

TABLE I—CHILDREN WET BY DAY

—	Wet by day only	Wet by day and by night	Total
Boys	7	30	37 (1·8%)
Girls	30	46	76 (4·1%)
Total	37	76	113 (2·9%)

In calculating these percentages a correction has been made for the fact that, whereas all children in the upper social groups who were born during the first week of March, 1946, were enrolled in the survey, only 1 of every 4 children in the manual working classes was enrolled (cf. Douglas 1951). This correction is made by giving the former groups a weight of unity and the latter a weight of 4.

We have excluded from this study all children whose histories at any of the three ages chosen were incomplete owing to temporary absence from the survey.[2] This reduced the number of children available from the original total of 4351 to 4294 (2268 boys and 2026 girls).

Children Wet by Day

Information about children who were wet by day was obtained when they were 6 years old, when 113 of them were reported to be wet by day. The numbers of boys and girls affected are shown in table I, the last column of which gives the prevalence for each sex.

Many more girls than boys are wet by day;[3] the sex difference is particularly striking among those who, although wet by day, were dry by night.

Owing to the relatively small number of affected children it is unprofitable to make a more detailed study of day wetting. All that need be said is that the variations in prevalence in the different groups of the survey population were, with the single exception of sex, closely similar to those reported below for bedwetters.

Bedwetting

Sex

We have divided the bedwetters (among whom were 3 mongols and 9 mentally defective) into those wet several nights a week (the regularly wet) and those wet less often (the occasionally wet). The proportion of children falling into these groups is shown in table II.

TABLE II—PREVALENCE OF BEDWETTING BY SEX (2268 MALES AND 2026 FEMALES)

—	Percentage frequency of bedwetting at age (yr.)		
	4¼	6	7¾
Regular bedwetters			
Male	3·69	4·00	3·55
Female	3·21	3·11	2·10
Occasional bedwetters			
Male	9·94	7·88	4·54
Female	7·34	5·31	4·11
Total			
Male	13·62	11·91	8·09
Female	10·55	8·42	6·11

Bedwetting, both occasional and regular, is consistently more frequent among boys than among girls. As regards regular bedwetting, the boys show no decline in prevalence during the survey period, whereas the prevalence among the girls drops by about a third. Thus the difference between the sexes, which is not quite significant at 4¼ years, is highly significant at 7¾ years.[4] The position is different for occasional bedwetters, among whom there is a steep decline for both sexes rather greater for the boys than for the girls. In this group the sex difference is highly significant at 4¼ and not significant at 7¾ years.[5]

4·3% of the boys and 2·8% of the girls were consistently wet throughout the whole survey period; most of them were reported as regularly wet on some occasions and occasionally wet on others.

TABLE III—PREVALENCE OF BEDWETTING BY PLACE IN FAMILY (REGULAR BEDWETTERS ONLY)

—	Percentage of regularly wet at age (yr.)			No. of children† (wet and dry)
	4¼	6*	7¾	
Firstborn	2·90	2·79	2·9[illegible]	[illegible]
Later born	3·76	4·02	2·9[illegible]	[illegible]

* $\chi^2 = 3{\cdot}68$ n = 1 $0{\cdot}1 > P > 0{\cdot}05$.
† There were 11 cards where information on place in family had not been punched.

When the prevalence of bedwetting in the two sexes is combined the proportion of children reported we no dislocation was present at first. He therefore recommended open fixation by wiring the spinous processes and bone grafting in all such cases; wiring alone was insufficient. Union was rapid and protection was required for three months only; there had been no deaths in 16 operations.

---

[1] A detailed account of the losses through death, emigration, &c. will shortly be published as part of a comprehensive report on the health, growth, and environment of the pre-school child. For an account of the sample and methods of the inquiry see Douglas (1951).

[2] These temporary absences were due to illness or to removal of a family which was still untraced at the time of the survey.

[3] $\chi^2 = 18{\cdot}767$ n = 1 $P < 0{\cdot}001$.

[4] Comparing the prevalence of regular bedwetting among boys and girls:
At 4¼ years $\chi^2 = 3{\cdot}800$ n = 1 $0{\cdot}1 > P > 0{\cdot}05$.
At 7¾ years $\chi^2 = 7{\cdot}622$ n = 1 $P < 0{\cdot}01$.

[5] Comparing the prevalence of occasional bedwetting among boys and girls:
At 4¼ years $\chi^2 = 13{\cdot}000$ n = 1 $P < 0{\cdot}001$.
At 7¾ years $\chi^2 = 2{\cdot}239$ n = 1 $0{\cdot}2 > P > 0{\cdot}1$.

Mr **Barnes** said that in these cases he applied both deep and superficial wiring to his grafts; this gave such stability that only the lightest collar protection was necessary. He suspected that cases of unilateral locked facets were always irreducible by traction alone and needed immediate open reduction.

Stress Fractures of the Fibula

Mr M. B. **Devas**, with Mr R. **Sweetnam**, had seen 50 cases of stress fracture of the fibula, all in athletes. All their patients were already in training, and the chief cause appeared to be running on a hard surface. A ten day history was common, and the usual complaint was of pain behind the ankle. In some cases the onset was sudden; in rather more it was gradual. A few had noticed local swelling; this was always slight, tender, and soft at first and later hard. "Springing" the fibula produced pain. Diagnosis was made on clinical grounds and not from radiographs, in which the changes were slight even after a month. A fine crack appeared often affecting only the lateral cortex, and running upwards, inwards and forwards; the periosteal reaction was minimal. The scar in the bone might remain visible for years. The majority (29 cases) occurred between 4 and 7 cm from the lower end of the bone; the highest seen was 23 cm up. Two thirds of the cases had occurred in the winter months, perhaps because at that time official tracks were being saved and training done on roads. They believed that the stress was due to muscle action each time the ball of the foot struck the ground; they demonstrated by special radiographic technique that static contraction of the calf muscles without ankle movement caused the upper two thirds of the fibula to approximate to the tibia, although the lower part remained unmoved. Patients must stop all sport until free from pain and then take up training gradually. Strapping was useful but plaster was definitely contra indicated. If pain recurred the patient must again reduce his activities.

Mr **Newman** remarked that he had seen cases affecting the upper third of the fibula in parachutists.

Mr **McKee** had seen 1 case progress to non union requiring excision and bone grafting.

Mr **Devas** thought that the stress fractures of the upper third of the fibula in parachutists were of a different nature and were due to repeated relatively severe injuries.

BRITISH INSTITUTE OF RADIOLOGY

Radioactivity in Man and his Environment

In a presidential address on June 24, Prof. F. W. **Spiers** discussed the background or natural radioactivity of Man and his environment.

Professor Spiers pointed out that Man has always been exposed to ionising radiations; in fact, he has always lived in a radioactive world. It now seems likely that, at least in geologically recent times, there has been no great change in the radiation intensity to which Man has been exposed in his environment. But Man has now begun to produce artificial radioactivity and ionising radiations in abundance, and Professor Spiers considers it possible, and perhaps likely, that the increase in radiation background now taking place will be greater than any changes in the past.

The human body is naturally irradiated in two ways: by sources of radiation external to the body, which include terrestrial and cosmic radioactivity; and by internal radioactivity acquired by the body from air, food, and water. The radiation dose acquired in this way is known as the "background dose."

The main contributors to terrestrial γ-radiation are the members of the uranium and thorium series, together with naturally occurring radioactive potassium. Swedish alum shale is an example of a particularly highly radioactive rock; granites are less active, and sedimentary rocks are considerably less active than granites. Sea water has a low radioactive content, the equivalent radium content of sea water is about 100 times lower than that of sedimentary rocks. High radioactivity can occur in mineral waters and well waters. The radioactivity of tap water is much reduced by precipitation methods of purification.

The natural radioactivity of the air is due to radon and thoron arising from the escape of these gases from the ground. Their local concentrations depend on local atmospheric conditions, as well as wind, rain, dust, and, in the case of buildings, their ventilation and fabric.

The radium content of the human body has lately been established as $0{\cdot}05\text{–}0{\cdot}32 \times 10^{-9}$ g. Since there is only a slight correlation between the body-radium content and drinking-water, it seems probable that the major source of this radium is food. The other main contribution to internal radiation is from radioactive potassium; the ^{40}K body content is now established at about 0·2% of body-weight. Radioactive carbon as ^{14}C, though present, is such a weak β-ray emitter that its contribution to radiation dose, compared with radium and potassium, is negligible.

There are three components of external radiation background: local γ-radiation, cosmic radiation, and atmospheric radioactivity.

Rock radioactivity is responsible for most of the external γ-radiation background. Higher dose rates are recorded inside buildings than in the open air, particularly if the building fabric contains a high proportion of radioactive material—for example alum shale in concrete. In general, wooden houses do not have very dissimilar dose-rates from those in the open air; brick buildings are intermediate between wood and concrete or concrete shale structures. The dose rates recorded vary from 48 to 50 m rad[1] per year out of doors or in Swedish wooden houses, to 171 m rad per year for concrete buildings with a high proportion of alum shale in the concrete.

Cosmic radiation at sea level in Northern latitudes contributes 28 m rad per year. This intensity is increased by altitude, and diminished by absorption in the basements of tall buildings.

Atmospheric radioactivity under normal conditions with a radon atmospheric content of 3×10^{-13} curie[2] per litre contributes about 4 m rad per year. This is small, but if the highest recorded values from London of $2\text{–}3 \times 10^{-12}$ curie per litre are used the γ ray dose is of the same order as that from cosmic radiation.

The internal radiation background is due to radioactive potassium primarily in soft tissues, ingested radium in bone, radioactive carbon, and radon and its disintegration products in air.

^{40}K is the main agent of soft tissue irradiation and is estimated to contribute 20 m rad per year mean dose, the dose rates to individual organs being determined by their potassium content. ^{14}C contributes about 1 m rad per year.

Bone dosage is likely to be particularly heterogeneous, but if 82 m rem[3] per year is received from sources other than radium, and if an osteocyte is 5 µ in diameter, the radium contribution is estimated to be 39 m rem per year, making a total dose-rate of 121 m rem per year to the osteocyte.

The contribution to the internal background radiation made by radon and its daughter products arising from their inhalation is uncertain, and depends on the assumptions made. It is probably of the order of 2·0 m rem per between children in England and those in Wales and Scotland

---

[1] rad is a unit of absorbed dose. It is 100 ergs per gramme (International Commission on Radiological Protection 1955.)

[2] curie is a unit of radioactivity defined as the quantity of any radioactive nuclide in which the number of disintegrations per second is $3{\cdot}700 \times 10^{10}$ (I.C.R.P. 1955.)

[3] rem is the absorbed dose of any ionising radiation which has the same biological effectiveness as 1 rad of X radiation with average specific ionisation of 100 ion pairs per micron of water in terms of its air equivalent in the same region. A dose in rems is equal to the dose in rads multiplied by the appropriate R.B.E. (relative biological effectiveness) (I.C.R.P. 1955.)

Effectiveness of Therapy

Of the 136 children regularly wetting their beds at $4^1/_4$ years 27 2% had become dry by the age of 6 years Of those regularly wet at 6 years 31 6% were dry at $7^3/_4$ years It is of interest to see to what extent the progress of these children is related to the measures taken to cure them We have no information about the earlier period, but, when the children were 6 years old, their mothers were asked about treatment The answers given were divided into the four broad groups shown in table VI, where they are related to the proportion of children cured and improved between the ages of 6 and $7^3/_4$ years

It might appear from this table that the best progress was made when there was no attempt at treatment, and the least progress when the child had been taken to a doctor or a clinic [11] It should be emphasised that we have no information about the selection of children for different types of treatment; it would, for example, be a sufficient explanation of these differences if only the children resistant to minor measures of reassurance and persuasion were taken to clinics or more actively dealt with by their parents

Discussion

The size of the problem of bedwetting is best shown if the percentages given above are used to calculate the number of children in the whole population who are affected at different ages at the current level of births Among children aged 4 years in Britain we would expect about 80,000 occasional and 30,000 regular bedwetters, and among children aged 7 years 30,000 occasional and 20,000 regular bedwetters At any one time there would be about a third of a million bedwetters aged $4^1/_4$–$7^3/_4$ years These numbers are based on the 1% Census Tables and on the prevalences given here, which agree closely with those reported by other workers—c f Bransby et al (1955)—and are, if anything, an underestimate

Comparisons of the prevalence of bedwetting in different social groups suggest that between a third and a half could be prevented by changes in upbringing and environment In other words, they show bedwetting as an important problem of public health Unfortunately, at present we have little knowledge of the various patterns of child-rearing in different sections of the community It is evident from the present inquiry that there are great social differences in the time that toilet training is started and control achieved, but, owing to the wide distribution of the sample, detailed histories of training are not available The poorest families start training latest and their children are also late in achieving control [12] In addition we find in each social group that early training is associated with a low prevalence, and late training with a high prevalence, of bedwetting at later ages [13]

These observations suggest that at least part of the social difference recorded is the result of different patterns of training That it is not wholly so is shown by the fact that among agricultural workers toilet training star late and the prevalence of bedwetting is low

The importance of bedwetting lies not only in its be a common source of worry and inconvenience to moth but also in its effects on the later adjustment of the chi This will be the subject of a further study, when we ha had greater opportunity to observe the progress of the children and to receive reports from their school teach and school doctors

Summary

The prevalence of wetting during the day and at nig among 2268 boys and 2026 girls drawn from all soci groups and from all parts of Great Britain is describ These children were observed throughout the first t years of their lives

At 6 years 1 8% of the boys and 4 1% of the girls we wet by day For both sexes together the prevalence day wetting was 2 9%

12 2% of all children aged 4 years wetted their bed and by the age of $7^3/_4$ years the proportion had dropp to 7 3%

At each age fewer girls than boys wetted their bed and among those severely affected—i e, who wett their beds several nights a week—the difference betwe the sexes increased with increasing age

These sex differences were most obvious (and on statistically significant) in the more prosperous familie

The lowest prevalence of bedwetting was found amon the well-to do and among agricultural workers Soci differences in prevalence were well marked for girls bu not for boys, and the high prevalence in the poore groups is partly explained by the large proportion of gir affected

More sibs of bedwetters wetted their beds than did th sibs of dry children

No significant differences in bedwetting were foun between firstborn and later born children, betwee children with younger sibs and those without, an between children living in different parts of Grea Britain

Bedwetting is an important problem for the child welfare and the school medical services since it appea that its prevalence could be considerably reduced b changes in upbringing or in environment But furthe research, particularly into patterns of child upbringin in the different social groups, is needed before effectiv preventive action can be taken

This survey is being made by a joint committee of the Institute of Child Health (University of London), the Societ of Medical Officers of Health, and the Population Inve ti gation Committee The chairman of the committee is Prof James Young the vice chairman Prof A A Moncrieff and the secretary Prof D V Glass The Nuffield Foundation has financed this inquiry during the pre school years and grants for continuing it in the primary school period have b made by the board of governors of the Hospital for Sick Children, Great Ormond Street through the Institute of Chil Health, and by the Ford Foundation Fourteen nationa hospital boards have also made grants to the inquiry fro their free moneys

We wish to thank the chairman and members of the join committee for their help and advice, the medical officers of health and the health visitors whose generous coöperation made the survey possible and the mothers in all parts of the country, who willingly answered numerous and detailed questions about their children s health

Reviews of Books

Medical History of the Second World War

Royal Naval Medical Services Vol II Operations Edited by Surgeon Captain J. L S COULTER D S C, R N H M Stationery Office 1956 Pp 543 *57s 6d*

THIS second volume concludes the official history of the Royal Naval Medical Service in the late war by describing the medical aspects of naval operations From many thousands of reports the editor has chosen those which illustrate the *special problems of war* and has presented them as a clear and orderly account by grouping them into those ashore and those afloat, and by considering each group chronologically and geographically *Occasionally he gives a section to the special matters* they illustrate, such as the type of injury caused by different weapons

The opening chapter deals with the general duties of a ship s surgeon as recorded in a daily journal which covers the commissioning of a cruiser and her service in the Mediterranean and with a Russian convoy during the next eleven months *There follows a detailed consideration of the lessons learned* from these experiences, including an excellent commentary on morale This chapter occupies nearly a fifth of the volume and provides the first published account of the individual and specialised way of life of the naval surgeon Even the four pages given to a singularly uninteresting daily sick list are of value in establishing perspective and balancing the long sequence of epic accounts that follow Many of these are in the narrators own words a few have been skilfully paraphrased *and all are accompanied by shrewd comments or* frank and fair criticisms Brief tables or statistical summaries complete these records

The difficulty of illustrating such a book has been successfully overcome but the publisher s lay-out is uneven and only in the last two thirds of the book are quotations printed in smaller type The three page index is inadequate

Wherever possible the editor has traced the later hospital history of patients treated in action showing the value of the simple measures first adopted These footnotes and statistics represent *a formidable amount of* research, and Captain Coulter is to be congratulated on maintaining such excellent control over his material never confusing the main pattern of the book by irrelevant digressions Stories of extraordinary endurance are inevitably *restricted by space the tented hospital in* Crete the R.N Hospital Hong-Kong during the attack and after the fall the varied and exciting adventures of the light-hearted and courageous junior M O of H M S *Gloucester* at her loss and in his subsequent captivity in *Greece and Germany* · *the affair of the M O* parachuted into South Serbia and later engaged with the guerillas against the Japanese in the Malayan jungles

Several passages reveal how the Admiralty s view of security unfortunately excluded ships surgeons and the medical department *itself from taking* part in planning— to the Navy s detriment Thus, the naval surgeons at the Normandy landings *were sometimes unaware of what* was intended and could make little provision for what was expected of them, while their R.A.M C colleagues had been fully briefed It is however, reassuring that selected medical officers are now trained in staff duties at Greenwich

The final impression is of a work well done which successfully achieves the dual aim of a proud record and a reference for the future

Diseases of the Chest

H CORWIN HINSHAW M D PH.D clinical professor of medicine Stanford University School of Medicine L HENRY GARLAND M B B CH clinical professor of radiology Stanford University School *of* Medicine Philadelphia and London W B Saunders 1956 Pp 727 105s

THE number of textbooks on diseases of the chest which have appeared in recent years reflects the general activity in this branch of medicine and this work is a worthy addition to the list It is intended as a practical reasonably concise, up-to-date guide for the student and practitioner rather than as an exhaustive treatise and the authors have on the whole succeeded in their aim

The exposition is clear the text is amply illustrated with chest films of excellent quality, and there is a good bibliography which concentrates on modern articles of the first importance A fair balance has generally been maintained *in the space allotted to different subjects* but it is surprising that there is no more than a passing reference to influenza and a less lopsided account of xanthomatosis and ' honeycomb lungs ' would be an improvement

Not everyone will agree with the views expressed on some minor points for example the pessimistic pronouncement that at bronchography it is a rare feat adequately to fill both bronchial trees at one sitting , or with the opinion that radiotherapy has a place however small, in the treatment of simple lung abscess

The book is written by a physician and a radiologist. and the value of such a partnership in chest work is rightly *stressed* nevertheless the *importance of the* radiologist is harped on so insistently that the reader may recall the celebrated advice " Codlin s *the friend* not Short " In sum however this is an excellent textbook which should take its place among the standard works

New Directions in Psycho-analysis

The Significance of Infant Conflict in the Pattern of Adult Behaviour Editors MELANIE KLEIN, PAULA HEIMANN and R E MONEY-KYRLE London Tavistock Publications 1955 Pp 534 38s

BITTER controversy about Melanie Klein s theory of early mental development rent psycho-analysis in this country for more than a decade but it has now abated As this volume testifies there is a group of psycho-analysts composed in about equal proportions of doctors and non-medical members who accept her teaching and apply it to very diverse problems

The first part of the book contains twelve essays on schizophrenia depression and other clinical subjects in the second part literary æsthetic ethical, and social issues are considered Some of the writers put forward their views tentatively others *confidently but it is clear that all are convinced that* Mrs Klein s picture of the " positions and ' defences ' of infantile development is correct There are also two papers by Mrs Klein herself one giving the history of her *psycho*analytic play technique, the other exemplifying through a *prolonged analysis of a story by Julian Green her view of* projective identification

In his preface Dr Ernest Jones says with repetitive emphasis that Mrs Klein's work is firmly established. The book hardly confirms this. but bears out Dr Brierley's judgment that the series of hypotheses put forward by Mrs Klein call for lengthy and critical evaluation. rather than *outright* acceptance or rejection

The Medical Care of the Aged and Chronically Ill

FREDDY HOMBURGER, M.D research professor of medicine Tufts College Medical School *Boston* Little Brown London J & A Churchill. 1955 Pp 253 42s

Dr Homburger insists on the importance of preventing the long-term degenerative illnesses which afflict the old. His teaching is directed to the general practitioner. and he deplores the prevalent over-specialisation

> The splitting of the medical profession into the atoms of specialities has brought great progress and developed supreme skills but it is time to put the puzzle together once more *for the emergence of the supra specialist* the competent practitioner who can treat and likes to treat the patient as a whole and not merely as so many cases of this or that "

His advice on the diagnosis and treatment of the rather intangible maladies of old age is detailed and sound The chapters on senile osteoporosis and *malnutrition* for example, are excellent Of inoperable cancer he writes " it is therefore extremely poor medicine to adopt a completely fatalistic attitude upon the discovery of neoplastic metastases and to give up in despair And he gives many examples of ways in which the life of such a patient can *be made tolerable He is* convinced of the value of daily exercises for all chronically ill patients He deplores the use of the bedpan while a between children in England and those in Wales and Scotland.

Effectiveness of Therapy

Of the 136 children regularly wetting their beds at $4^{1}/_{4}$ years 27.2% had become dry by the age of 6 years. Of those regularly wet at 6 years 31.6% were dry at $7^{3}/_{4}$ years. It is of interest to see to what extent the progress of these children is related to the measures taken to cure them. We have no information about the earlier period; but when the children were 6 years old, their mothers were asked about treatment. The answers given were divided into the four broad groups shown in table VI, where they are related to the proportion of children cured and improved between the ages of 6 and $7^{3}/_{4}$ years.

It might appear from this table that the best progress was made when there was no attempt at treatment, and the least progress when the child had been taken to a doctor or a clinic.[11] It should be emphasised that we have no information about the selection of children for different types of treatment; it would, for example, be a sufficient explanation of these differences if only the children resistant to minor measures of reassurance and persuasion were taken to clinics or more actively dealt with by their parents.

Discussion

The size of the problem of bedwetting is best shown if the percentages given above are used to calculate the number of children in the whole population who are affected at different ages at the current level of births. Among children aged 4 years in Britain we would expect about 80,000 occasional and 30,000 regular bedwetters, and among children aged 7 years 30,000 occasional and 20,000 regular bedwetters. At any one time there would be about a third of a million bedwetters aged $4^{1}/_{4}$–$7^{3}/_{4}$ years. These numbers are based on the 1% Census Tables and on the prevalences given here, which agree closely with those reported by other workers—c.f. Bransby et al. (1955)—and are, if anything, an underestimate.

Comparisons of the prevalence of bedwetting in different social groups suggest that between a third and a half could be prevented by changes in upbringing and environment. In other words, they show bedwetting as an important problem of public health. Unfortunately, at present we have little knowledge of the various patterns of child rearing in different sections of the community. It is evident from the present inquiry that there are great social differences in the time that toilet training is started and control achieved; but, owing to the wide distribution of the sample, detailed histories of training are not available. The poorest families start training latest, and their children are also late in achieving control.[12] In addition we find in each social group that early training is associated with a low prevalence, and late training with a high prevalence, of bedwetting at later ages.[13]

These observations suggest that at least part of the social difference recorded is the result of different patterns of training. That it is not wholly so is shown by the fact that among agricultural workers toilet training st late and the prevalence of bedwetting is low.

The importance of bedwetting lies not only in its b a common source of worry and inconvenience to moth but also in its effects on the later adjustment of the ch This will be the subject of a further study, when we h had greater opportunity to observe the progress of th children and to receive reports from their school teac and school doctors.

Summary

The prevalence of wetting during the day and at n among 2268 boys and 2026 girls drawn from all so groups and from all parts of Great Britain is descr These children were observed throughout the first years of their lives.

At 6 years 1.8% of the boys and 4.1% of the girls w wet by day. For both sexes together the prevalence day wetting was 2.9%.

12.2% of all children aged 4 years wetted their b and by the age of $7^{3}/_{4}$ years the proportion had drop to 7.3%.

At each age fewer girls than boys wetted their be and among those severely affected—i.e., who wet their beds several nights a week—the difference betw the sexes increased with increasing age.

These sex differences were most obvious (and o statistically significant) in the more prosperous famil

The lowest prevalence of bedwetting was found amo the well-to-do and among agricultural workers. So differences in prevalence were well marked for girls b not for boys, and the high prevalence in the poor groups is partly explained by the large proportion of g affected.

More sibs of bedwetters wetted their beds than did t sibs of dry children.

No significant differences in bedwetting were fou between firstborn and later-born children, betwe children with younger sibs and those without, a between children living in different parts of Gre Britain.

Bedwetting is an important problem for the chil welfare and the school medical services since it appe that its prevalence could be considerably reduced b changes in upbringing or in environment. But furth research, particularly into patterns of child upbringi in the different social groups, is needed before effecti preventive action can be taken.

This survey is being made by a joint committee of th Institute of Child Health (University of London), the Soci of Medical Officers of Health, and the Population Inv gation Committee. The chairman of the committee is Pro James Young, the vice-chairman Prof. A. A. Moncrieff, an the secretary Prof. D. V. Glass. The Nuffield Foundation h financed this inquiry during the pre-school years, and grant for continuing it in the primary school period have be made by the board of governors of the Hospital for S Children, Great Ormond Street, through the Institute of Chi Health, and by the Ford Foundation. Fourteen region hospital boards have also made grants to the inquiry fro their free moneys.

We wish to thank the chairman and members of the join committee for their help and advice; the medical officers o health and the health visitors, whose generous coöperatio made the survey possible; and the mothers in all parts o the country, who willingly answered numerous and detail questions about their children's health.

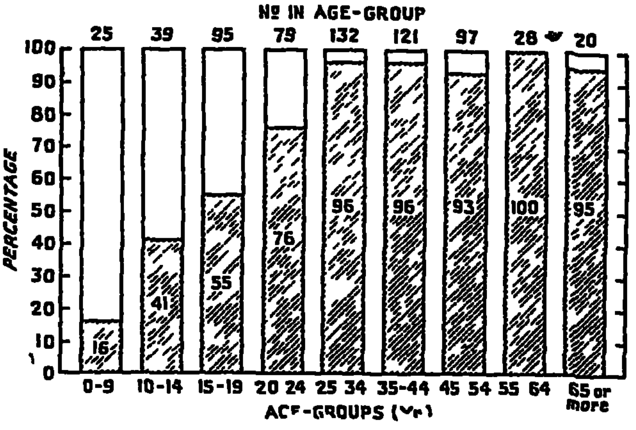

Fig 2—Results of tuberculin testing

led to recall for a full sized film again taken by the mass radiography unit In some cases the patient was too ill or too uncooperative for this to be done, in such cases the hospital portable apparatus was used In some patients it was necessary to make several exposures before a completely satisfactory film was obtained

Clinical and Bacteriological Examination —Where any significant abnormality was detected on the full sized chest radiograph the patient was examined clinically and as complete a history as possible was obtained Attempts were made to obtain sputum for examination by microscopy of the concentrated deposit and by culture for tubercle bacilli Many of the specimens obviously did not come from the patient's lower respiratory tract Whenever no sputum could be obtained an attempt was made to isolate tubercle bacilli from laryngeal swabs and fæces

Results

Tuberculin Testing —All 636 patients in the hospital at the start of the survey were tuberculin tested, and 512 (80 50%) were positive Fig 2 shows the result of tuberculin testing according to age groups 80 22% of males and 80 88% of females were positive in each age group the percentage positive was similar for males and females and the results are shown for both sexes together

Radiography —Of the 512 tuberculin positive patients at the start of the survey 6 left the hospital and 1 died of non tuberculous disease before the radiographic survey The remaining 505 positive reactors all had satisfactory chest radiographs and 32 of these were considered to be abnormal 25 of the 124 tuberculin negative patients were radiographed and 2 of these radiographs were abnormal Table II shows the result of the radiographic survey

Bacteriology —Specimens were examined bacteriologically in every case where tuberculosis seemed a possible diagnosis No tubercle bacilli were found in any specimen

TABLE II—FINAL RESULTS OF SURVEY

—	Males	Females	Total
Population surveyed	359	270	629
Abnormal lungs	26 (7 24%)	8 (2 96%)	34 (5 41%)
Non tuberculous lung disease	7 (1 95%)	1 (0 37%)	8 (1 27%)
Respiratory tuberculosis	19 (5 30%)	7 (2 59%)	26 (4 14%)
Significant tuberculosis	17 (4 74%)	6 (2 22%)	23 (3 66%)
Active tuberculosis	7 (1 95%)	4 (1 48%)	11 (1 75%)
Observation tuberculosis	10 (2 79%)	2 (0 74%)	12 (1 91%)
Insignificant tuberculosis	2 (0 56%)	1 (0 37%)	3 (0 48%)

Diagnosis and Classification —Final diagnosis in each case was reached mainly on an interpretation of the radiograph or a series of radiographs In many cases the diagnosis of tuberculosis was not considered beyond doubt until some months had elapsed and serial radiographs had been taken In all doubtful cases where the lesion may have been non tuberculous pneumonia the response to penicillin was assessed radiographically as a first step The response to antituberculous drugs also helped in reaching a diagnosis All the patients were allocated to two main groups—tuberculous and non tuberculous The tuberculous patients were grouped into those with insignificant and those with significant lesions, the latter being further divided into those thought to be active and therefore requiring treatment and those thought to be quiescent but still requiring careful observation Table II shows the final results of the survey classified as described

Discussion

The results of the present survey are similar to those already published Of 629 patients 23 (3 66%) showed significant tuberculosis, of which 11 cases (1 75%) were considered active 7 of the active cases were in males and 4 were in females 3 showed definite cavitation 6 of the cases of significant tuberculosis were previously known to the hospital authorities There is no reason to suppose that the prevalence of pulmonary tuberculosis in the hospital surveyed was any higher than in other similar institutions Oechsli (1949) has shown that the prevalence of tuberculosis in mental hospitals may be twice as great as in mental defective institutions

It is particularly appropriate that attention should be drawn to this state of affairs when the mental hospital service is undergoing development Not only is the problem serious for patients within the hospital, but also with the present improvements in treatment and the resulting high discharge rate of patients to their own homes measures should be taken to prevent the spread of tuberculosis in the general community by patients who have been discharged from mental hospital and have developed tuberculosis while in hospital In 1954, in England and Wales, 65,329 patients left mental hospitals and institutions for mentally defectives and returned to life in the general community the corresponding figure for Scotland is 6476

Control of Tuberculosis in Mental Institutions

The steps necessary for the control of tuberculosis in mental hospitals are well known and have been applied with encouraging results in several countries, particularly the United States With the advent of effective chemotherapy and its facilitation of sputum conversion even in chronic and advanced cases, it should be possible to produce better and more rapid results We suggest the following scheme of control

(1) Survey of all patients including tuberculin testing and radiography of positive reactors Where possible, negative reactors should also be radiographed

(2) Thorough investigation of all cases with abnormal radiographs and segregation of those with significant pulmonary tuberculosis

(3) B C G vaccination of all negative reactors to tuberculin once segregation of all possible sources of infection has been secured

(4) Annual radiography of all patients whether or not they have been radiographed in the preceding months

(5) Radiography and tuberculin testing of all newly admitted patients and immediate segregation of any showing abnormalities suggesting tuberculosis, and B C G vaccination of negative reactors to tuberculin

Possibly these measures could best be implemented by setting up special units for mental patients with

"Anæmia" in Pregnancy

In a recent issue Dr Edgar and Dr Rice[1] raised the question whether it is desirable to give iron supplements to *all* pregnant women. They showed once again, how the hæmoglobin level in the peripheral blood falls during pregnancy; the mean hæmoglobin in their patients when the pregnancy was 5–8 weeks advanced was 91.8%, and at 33–36 weeks it was 76.7%. At the 5–8 week stage only 0.7% of the women had a hæmoglobin level of less than 70% (10 g. per 100 ml.). In their patients the mean corpuscular hæmoglobin concentration (M.C.H.C.)—a measure of iron deficiency—was 30.2%, a figure indicating, according to Discombe, iron deficiency short of anæmia. Edgar and Rice gave a daily supplement of iron in the form of tab. ferri sulph. co. gr. 9 (0.6 g.) daily; since the familiar green tablets have so often caused nausea or vomiting, they used white-coated tablets and only 5% of their patients reported intolerance. This dose of iron was given to a group of pregnant women of whom 89 were carefully followed through pregnancy. In 69 a normal hæmoglobin level was maintained throughout and the M.C.H.C. remained normal too; in the remaining 20 there were various degrees of falling away from normal.

The gradual fall of the hæmoglobin level in the peripheral blood in pregnancy has long been attributed to an increase in the plasma-volume, and the lowered hæmoglobin level was thus thought to be due to dilution rather than to anæmia. The calculation of the blood-volume has, in most investigations, been made indirectly from the venous hæmatocrit value and the estimation of plasma-volume by the Evans blue dilution technique. But Verel et al.,[2] who have reinvestigated this question, point out that the calculation depends on the assumption that the venous hæmatocrit bears a constant relation to the body hæmatocrit. In health the two figures are almost identical, but in disease and in pregnancy this is not necessarily the case. They therefore made simultaneous estimations of the plasma volume, by the usual Evans-blue method, and the red-cell volume, using radioactive phosphorus (^{32}P). They found that in pregnancy the ratio of body hæmatocrit to venous hæmatocrit varied unpredictably, and consequently it was necessary to re-examine the question of blood changes in pregnancy using separate estimations of red-cell and plasma volumes. Fortunately the new results do confirm previous views. Comparison with measurements made on a series of non-pregnant women showed that, when properly related to body-weight, the plasma-volume increased during pregnancy, and in addition the red-cell volume was maintained or even increased in 2 out of their 13 subjects. This maintenance or rise of the red-cell volume during pregnancy has received less attention than the dilution effect of the bigger increases of plasma-volume, but it has been recognised for some time. Caton et al.[3] found a definite rise in red-cell volume in their series of patients, though there was much individual variation. Wilson and Boyle[4] pointed out that the red-cell mass was increased in all their 5 patients, but the rise was proportionately not as large as that of the plasma-volume.

All these data suggest that the gradual lowering of the hæmoglobin level in the peripheral blood to about 10 g. per 100 ml. during pregnancy cannot be properly classified as "anæmia," if anæmia means that there is insufficient hæmoglobin to carry the oxygen the patient needs; for it is clear that the red-cell mass is either unaffected or actually increased. Clinical observation had, in fact, led to much the same conclusion; and many obstetricians consider as "anæmic" only those pregnant women whose hæmoglobin is less than 10 g. per 100 ml. (70%). With this definition, other observers have recorded figures very like those of Edgar and Rice. For example, Gatenby and Lillie,[5] in Dublin, found 24% of their pregnant patients to be anæmic by this criterion, and 9% of them were below 9 g. per 100 ml.; they noted too that symptoms attributable to the anæmia rarely become prominent at hæmoglobin levels above 6 g. per 100 ml. (45%). Edgar and Rice have therefore suggested that all pregnant women should have two hæmoglobin estimations, one when they first come to the antenatal clinic and the second between the 32nd and 36th weeks. Those with a hæmoglobin level of at least 70% are given a small dose of iron (gr. 9 of ferrous sulphate daily) to take throughout the pregnancy, but no further investigation is made. Those whose hæmoglobin level is less than 70% are sent for proper hæmatological investigation.

The form of this proper investigation is now established. Owing to the changes in the relations between plasma-volume and red-cell mass the colour-index is useless for diagnosis. We rely on the M.C.H.C. for the detection of iron deficiency and on sternal-marrow examination for the detection of the megaloblastic anæmia of pregnancy. Probably 9 out of every 10 patients with anæmia of pregnancy in this country are iron deficient. A fair proportion of these will respond quite satisfactorily to oral iron, and, as O'Sullivan et al.[6] pointed out, moderate doses of ferrous sulphate or ferrous gluconate will suffice. Increasing the dose beyond 0.6 g. daily of ferrous sulphate or 2 g. daily of ferrous gluconate brings proportionately much less benefit at the cost of a steeply rising intolerance-rate. It is better, in patients not responding to these doses of oral iron, to give parenteral iron, and, now that reliable intravenous and intramuscular preparations are available, such treatment should present no difficulties. But parenteral iron needs time to become effective; about 2 weeks elapse by either route before there is

Tracing the Source of Infection

Swabs were placed in the sewer in three different places (1) near the manhole from which the sewage had escaped, (2) at a sewer junction about 200 yards away, and (3) at a pumping station half a mile away through which passed sewage from most of the houses on the south side of the town These swabs consisted of rolled-up pieces of gauze and were suspended in manholes at such a level that the sewage flowed over them They were left in situ for three days

The first examination produced negative results in all cases When it was repeated, however, the swabs from the sewer junction and the pumping station grew *Salmonella typhi*

Meanwhile I had looked through my records and found that in the previous 28 years there had been five cases of typhoid in Farnham Inquiries showed that one of these patients could not be traced, one had left the district, one was dead, and two were still living in Farnham One of these was the patient's uncle and had had typhoid 26 years ago He was immediately suspected, but he lived in a different house and had not seen the patient for some six to eight weeks before the onset of the illness

Fæces and urine from these two ex-typhoid patients were examined but gave negative results Because they might be excreting bacilli intermittently, swabs were placed in the manholes of the sewers from each of the houses occupied by these people Immediately, a positive result was obtained from the house occupied by one of the ex-typhoid patients, who lived on the south side of the town and had had typhoid 5 years ago The other specimens were negative Further positive results were obtained from the pumping station and a sewer through which the sewage from the affected house flowed

The man who had had typhoid was naturally thought to be the source of this contamination, but three consecutive specimens of urine and fæces all gave negative results

The only other occupants of the house were his wife and his mother-in-law, Mrs A Specimens were then obtained from them, and those from Mrs A gave positive results in urine and fæces

This woman, aged 74, had spent many years of her early life in India and Egypt, and although she had never to her knowledge had typhoid she did have some obscure and prolonged illness just previous to and after the birth of her daughter about 35 years ago This was probably typhoid 30 years ago her son had typhoid at the age of 3 years Her son-in-law Mr B, when he had typhoid 5 years ago, was living in a different house but stated that he often had meals with Mrs A

Cultures from the patient, the sewer swabs, and Mrs A all belonged to the same untypable Vi strain and were identical with that obtained from Mr B 5 years previously It seems reasonable to assume, therefore, that Mrs A had typhoid in Egypt some 35 years ago and has been excreting bacilli ever since and, as a result, infected her son 30 years ago, her son-in-law 5 years ago, and, lastly, the boy who had been paddling in the contaminated sewage

Points of interest are as follows

(1) The place where the boy was paddling was at least three miles from the original source of infection, and the sewage was heavily diluted with storm water

(2) Although Mrs A had probably been excreting typhoid bacilli for some 35 years she has so far as we know, infected only three people

(3) The swabs placed in the sewers gave consistent results

Treatment of the Carrier

The treatment of typhoid carriers is extremely unsatisfactory Recently, promising results were reported from America from using 3 mega units of penicillin every six hours together with probenecid 1 5 g twice daily for ten days (Parker et al 1953)

C A Rumball (Ministry of Health, personal communication), in dealing with R A F cases abroad used 2 mega units of penicillin three-hourly with 0 5 g of probenecid six-hourly for seven days, together with 5–8 g of sulphadimidine daily The essence of the treatment is to secure and to maintain a high blood penicillin level by combining it with probenecid, which temporarily inhibits the renal tubules The treatment has been used in this country in mental hospitals, where typhoid carriers are somewhat common

According to Dr Grant Nicol (personal communication), of the Ministry of Health, the results so far to hand have been very variable, but about 30% of the carriers treated ceased to excrete bacilli and remained free for a year or more Others relapsed as soon as the treatment was stopped The treatment is not without risk, particularly to people with damaged kidneys or a poor cardiovascular system

Before treating a patient it is advisable, therefore to investigate thoroughly the cardiovascular system and to make an electrocardiogram, besides testing the kidney functions (blood-urea level, urea concentration test, and alkali reserve)

Treatment would consist of 28 or 56 injections of penicillin according to the method adopted, and the blood-penicillin level should be checked after 24 hours and 3 days to see that a satisfactory concentration of penicillin is being obtained

The present carrier is a frail old lady aged 74, and I did not think it desirable to subject her to all this with only a 30% chance of cure, and instead gave her a course of tetracycline, which I recently found to be very effective in the treatment of Sonne dysentery It did not, however, have any effect

I should like to acknowledge the great help received from Dr G T Cook, of the Public Health Laboratory at Guildford in the pathological investigations

Contaminated Flour

The poison responsible for the outbreak[1] at Pontardawe, Glamorgan, has been identified as 'Endrin', an isomer of dieldrin, which is a constituent of certain pesticides and insecticides Further investigations are being made to discover how the flour became contaminated, but there is no evidence whatever that it happened during crop spraying or any other insecticidal measure Over 100 people were involved, and they became ill one to three hours after eating the poisoned bread Those most severely affected had epileptiform fits They all recovered

Spilled Virus

Four boxes of poliomyelitis virus were carried by aeroplane last week from Washington to Baltimore and when they arrived one was found to be broken and its contents spilled[2] The crew and cargo handlers were given injections of poliomyelitis vaccine and the aircraft was decontaminated At the suggestion of Dr Salk passengers were advised to have gamma globulin

Another Hazard of Smoking

The manager of a grocer s shop in Acton, London smoked his pipe while at the bacon slicer, with uncovered bacon and cheese nearby[3] He had previously been warned by a sanitary inspector that he was liable to prosecution under the new Food Hygiene Regulations[4] He was fined £10 and 2 guineas costs

alike. Yet it is not clear why the recruit population should not have already acquired immunity to the virus nor is it known why epidemics have not been discovered among the civilian population. Furthermore DINGLE and FELLER[2] point out that although clinically similar syndromes among recruits and seasoned men are extremely common, the large majority are not caused by influenza or A.P.C. viruses. There is clearly a great deal of combined clinical and laboratory investigation still required in this field.

On the other hand, investigation of the cause of non-streptococcal summer sore throats has shown the rôle of at least three different viruses, which may well account for a large proportion of these conditions. Herpes-simplex virus causes herpetic stomatitis, some of the group-A Coxsackie viruses have been identified by HUEBNER and his colleagues as the cause of herpangina,[10] and now this same group of workers have found that type-3 A.P.C. virus is the cause of what they call 'pharyngo-conjunctival fever'.[6] This is an acute febrile illness, occurring particularly in children, in whom pharyngitis, occasional rhinitis, conjunctivitis (often unilateral), and cervical lymph-gland enlargement are the main features. Nowadays the interval between the discovery of a virus and the production of a vaccine against it grows steadily less, and although a good deal remains unknown about the disease-producing powers of the A.P.C. viruses it is encouraging to know that whatever disease emerges from this jungle of viruses there will almost certainly be a vaccine waiting to meet it. HUEBNER et al.[11] have prepared a vaccine from inactivated type-3 A.P.C. virus and injected it into human volunteers. The volunteers and uninoculated controls were challenged by inoculating live virus on to their conjunctivæ. An illness similar to the natural infection was produced in some of the volunteers and in a significantly smaller proportion of the vaccinated individuals. So far there have unfortunately been no confirmed reports of how to grow the common-cold virus or even how to make an efficient common-cold vaccine.

Fort mit dem Spray!

"In the year of our Lord 1536 Francis the French King sent a puissant army beyond the Alps. In the conflict there were many wounded on both sides with all sort of weapons but chiefly with bullets. I will tell the truth," PARÉ continues, "I was not very expert at that time in matters of Chirurgie. . . . I observed and saw that all the Chirurgions used that method of dressing which Vigo prescribes . . . that they filled, as full as they could the wounds made by gunshot with tents and pledgets dipped in scalding oyle at the first dressing. . . ."[12] And as befits the neophyte—for he was 27 and this was his first campaign—he followed their example assiduously. Then came his discovery:

> "I chanced on a time when by reason of the multitude that were hurt I wanted this oyle. Now because there were some few left to be dressed I was forced—so that I might seem to want nothing and that I might not leave them undressed—to apply a digestive made of the yolk of egg, oyle of roses and turpentine. I could not sleep all that night, for I was troubled in minde; and I feared that the next day I should find those whom I had not dressed with the scalding oyle dead, or at the point of death, by the poison of the wound. Therefore, I rose early in the morning; I visited my patients, and, beyond expectation, I found such as I had dressed with the digestive only free from vehemence of paine; but on the contrary the others that were burnt with the scalding oyle feverish and tormented . . . and the parts around their wounds were swolne."

No thunder, lightning, or other heavenly sign proclaimed to the world that the surgical Middle Ages had come to an end. The world remained intensely preoccupied with the petty squabbles of FRANCIS the French King and CHARLES the Emperor, while PARÉ jotted down the immortal summary: "Je le pansay, Dieu le guerit."

But PARÉ was not the first to revolt against the use of scalding oil and cauteries as a means of wound dressing. Over two hundred years earlier HENRI DE MONDEVILLE had written:

> "Wash the wounds scrupulously from all foreign matter, use no probes, no tents, except under special conditions; apply no oils or irritating matters. When your dressings have been carefully made do not interfere with them for several days. Do not pull your dressings about; Nature works better alone."[13]

More than a thousand years before him the physicians of Cos advocated not only gentle irrigation of wounds, to obtain primary healing, but also the careful cleansing of hands—and especially the nails—before operating. And (amid much cant and superstition) the compilers of the Ebers papyrus recorded in 1500 B.C. that their treatment of wounds consisted in simple apposition of the edges by linen bandage, held in place for three to four days by myrrh and honey.[14] Indeed the closer we look at medical history, the more we recognise the truth in old Sir 'Paddy' Cullen's mockery: "Modern science is a wonderful thing. Look at your great discovery! Look at all the great discoveries! Where are they leading to? Why, right back to my poor dear old father's ideas and discoveries. He's been dead now over forty years."

The other day we discussed experiments by PALUMBO et al.[15] from which they conclude that clean surgical incisions heal as well without dressings as with them. These observations recall some described forty-four years earlier by WEBB-JOHNSON[16] in the *Archives of the Middlesex Hospital*:

> "I have felt for some time that the careful application of layer after layer of dressings to closely sutured operation wounds was possibly an unnecessary waste of time, energy and material. An article by Mr. Reginald Alcock[17] on 'Iodine as the sole dressing of Operation Wounds' . . . therefore naturally aroused my interest. His results were so good that I felt not only justified but encouraged in giving the method a trial. . . . Not only has apparently unnecessary trouble been saved, but the patients have expressed themselves as being most comfortable. One or two patients who had undergone operations before and had experienced the discomfort of dressings and bandages were very pleased to be without these encumbrances. I consider that the wounds healed even better than when dressings are employed, and in no case in which I used the method did the slightest inflammatory reaction occur."

Letters to the Editor

BURNS AND SCALDS

SIR,—Your editorials are so rightly esteemed for their sense of fair play and balanced judgment that I hope you will permit one who has made a close study of burns for more than ten years to offer comment which differs somewhat from the views expressed in your leader of May 19.

That leader was, in effect, a reply to a correspondent whose unhappy experience of his wife's scalded foot treated by exposure to air had left him unconvinced of the merit of that procedure; and the leader offered guidance to others (especially general practitioners) faced with the management of common injuries of this type. But was your guidance, Sir, very helpful? You told your readers that "the modern treatment" of burns is by exposure to air, and then went on immediately to mention certain undesirable features of that method—the pain involved "may be considerable," and there is good reason to question its efficacy as a means of preventing bacterial infection of the burned surface. In this last connection you rightly reminded readers that Lowbury and his colleagues[1] had shown that, while the dried surface of the eschar remained sterile or nearly sterile, its inner surface, next to the regenerating tissues, was often heavily contaminated by pathogenic bacteria. (Actually this was observed in all of six cases investigated.) Other observations pointed in the same direction—to the more frequent infection of burns treated by exposure. These workers concluded with the fair comment: "A place still exists for both kinds of treatment, and exposure is often indicated on clinical grounds or because adequate cover with dressings is impossible" (i.e., especially in burns of the face and buttocks).

What was the practitioner confronted with the scalded foot of an old lady to conclude from all this? Would he not ask himself: "Is there no surer way of avoiding infection, and all the pain of frequent dressings, the slow healing, and the poor final result which so often follows"? Your leader, Sir, offers him as the *only* alternative to the exposure method "ointments or picric acid"—treatments in vogue in 1930. There is no mention whatever of penicillin cream, which is still after ten years' experience with more than 3500 burned patients, regarded by the Birmingham workers as a most valuable agent for avoiding streptococcal infection. (Creams of some of the other antibiotics are equally valuable but very much more expensive.) Was this unique body of experience not even worthy of a passing mention? Nor the most illuminating fact that, in a carefully controlled clinical trial, Jackson et al.[2] had shown that, whereas only 1·7% of 58 burned sites (in 27 patients) acquired a streptococcal infection after the prophylactic application of penicillin cream, no less than 38% of 42 burned sites acquired such an infection in 19 patients not so treated. Surely, in view of the great importance of streptococcal infection in the burned patient, that observation was one of the most valuable signposts that has been set up in the past twenty years?

And it had particular relevance to your correspondent's scalded foot, since that is par excellence a lesion which can be effectively covered to protect it against both airborne and contact infection. (In Birmingham only 1·6% of all burns of the foot became infected by streptococci after treatment by penicillin cream and careful coverage.) After seeing some hundreds of such injuries so treated one may confidently hazard the guess that had the scalded foot of your correspondent's wife been covered generously with penicillin cream she would have had no pain at all from that time; her burn would almost certainly have escaped streptococcal infection; it would have healed in about three weeks (allowing for her age) if the injury was superficial, or it could have been grafted at an early stage with an optimal chance of success if that had been judged necessary.

Readers may well be asking: "Why did the leader not mention penicillin cream and the evidence of the Birmingham unit"? Why indeed? It appears that you had in mind the opinion of some plastic surgeons (*not* the whole Association of Plastic Surgeons) that the use of penicillin in this way entails "too great a risk of generalised sensitivity in the patient, or of insensitivity in the bacterial population." With reference to this opinion (which was, and I think still is, unsupported by any factual evidence based on experience of a large number of patients) I would refer your readers to the very informative letter by Bull and his colleagues[3] who stated that observation of more than 3000 inpatients at Birmingham had shown sensitivity to be "rare and transient." That is still their experience today. And perhaps I may recall, Sir, that your own wise comment[4] on this conflict of opinion was to the effect that readers who wished to arrive at the truth would choose between a clinical impression and a controlled trial. With regard to the other alleged risk of prophylactic penicillin—that it will favour the development and dissemination of organisms insensitive to that agent—Bull and his colleagues made the effective reply that this had already happened in many hospitals where prophylactic applications were not being used.

In conclusion, may I suggest that the most urgent need for the better treatment of the many burns which could be dealt with at home is of a penicillin preparation for local application which is stable at ordinary temperatures, or of another equally effective and inexpensive antibiotic. The exposure method has been on trial all over the world for seven or eight years, and most surgeons now recognise its considerable limitations. The time has come for a return to wisely directed local prophylaxis, combined, when possible, with dressing in clean air and other measures calculated to reduce the chance of infection. We should no longer be complacent about infection. Let us get rid of it.

Farnham Royal, Bucks. LEONARD COLEBROOK

SIR,—The letter from your correspondent "Unconvinced" (May 19) raised several points, some of which were answered very clearly in your editorial. The difficulties in diagnosis of the depth of burns and scalds are well known: the clinical appearance on admission is often grossly misleading, and the pin-prick test demands good cooperation from the patient at a time when he is least likely to give it. It may prove possible to devise tests for burn depth by the intravenous injection of suitable dyes or radioactive isotopes. Indeed, one such dye is under investigation at this hospital. But I would suggest that an accurate history of the accident and the immediate first-aid measures employed may give a good lead as to the depth of the burn or scald.

The popular misconception that a scald is less serious than a burn is still widespread amongst both medical and lay workers. Yet our experience at the regional burns centre for Wales shows that a considerable proportion of the scalds sent to this hospital require skin grafting. For instance, of 108 cases of domestic scalds admitted during 1955, 54% required grafting. During the same period, 118 domestic burns were treated, of which [illegible] needed grafting.

The types of scald that are likely to prove serious are:

(1) Those in which the boiling liquid falls on to uncovered skin—e.g., hands, forearms, legs, and neck.

[1] Lowbury, E. J. L., Crockett, D. J., Jackson, D. M. *Lancet*, 1954, ii, 1151.

[2] Jackson, D. M., Lowbury, E. J. L., Topley, E. *Ibid*, 1951, ii, 705.

[3] Bull, J. P., Jackson, D. M., Lowbury, E. J. L. [illegible] 1951, i, 161.

[4] *Ibid*, p. 298.

Neither conclusion can be accepted without comment, and it is instructive to seek the reason for their differences. The American workers, with much larger numbers, compare mortality-rates but do not discuss duration of life in relation to treatment. Moreover, their comparison is made not between treated and untreated patients but between those who have received more or less than an arbitrarily defined "adequate" dose of arsenic. This method, though hallowed by tradition, particularly in American studies of syphilis, is of doubtful validity, because no-one really knows what constitutes adequate treatment for cardiovascular syphilis, and doses of the same drug above or below an arbitrary minimum "adequate" quantity may not be very different in their effects. Gamble gets over this difficulty by selecting for comparison totally untreated patients and those who received at least 3 g. of arsenic, and he goes to great lengths to ensure that his treated and control groups should be comparable in other ways. Unfortunately, in doing so, he is forced to discard large numbers of cases, so that his final conclusions are drawn from very small groups, the largest of which contains only 17 cases, and this makes his results rather less convincing. Finally, both studies suffer from the defect that the treatment was deliberately chosen by the doctor in charge and was not selected at random.

In the arsenical era to which these papers relate it was a matter of importance to decide whether life was prolonged in cardiovascular syphilis by a treatment which carried a considerable risk of poisoning or exhausting the patient. Since the introduction of penicillin, however, with its indisputable effectiveness in other forms of syphilis, with its safety and ease of administration, the question whether to give or withhold specific treatment is no longer a live issue. Although no drug can be expected to deal with the mechanical problems of a damaged aorta or an incompetent aortic valve, it seems possible that the process may be retarded by penicillin, and it now remains to be decided what is the proper dosage of this antibiotic. The difficulties of clinical trials in cardiovascular syphilis may mean that the ultimate answer is provided not by the clinician but by the pathologist, and there is need for further work on the histological criteria of active syphilis in the aorta. Such studies might reveal the need to continue treatment for longer than has been customary hitherto.

NON-CELLULAR HISTOLOGY

HISTOLOGY has always been recognised as a little bit of science and a lot of art, and some would say a pretty mystical art at that. Even books bearing the title of *histochemistry* seem full of formulæ for revealing the distribution in cellular sections of sphingolipides or glycoproteins. But cells are no longer the only preparations with proteins and lipoids and carbohydrates distributed throughout their bulk. Every paper electrophoretic strip (and thousands must be produced each day) confronts the biochemical analyst with the same question that faces the histologist: "what is the distribution of interesting components throughout this preparation I have made?" The methods used to reveal, with varying degrees of specificity, the required components on the paper strip are often those of proved histological worth—azocarmine for proteins, Sudan Black for lipides. But Uriel and Grabar[1] go one better: they prepare their electrophoretic medium as a thin transparent film of agar, and the components of the solution under investigation are finally distributed along the strip in a pattern determined by their electrophoretic mobilities and relative amounts. The agar film is then treated like a tissue section, fixed, dehydrated, mounted on glass, and stained by histological procedures. The resulting strip is like a large histological slide, permanent and easily handled, and transparent so that direct photometry is possible.

Perhaps the strip could be more truly likened to a photographic colour transparency, and it might be possible to project the pattern like a lantern slide if it was protected against the heat. Uriel and Grabar do not mention counter staining of their agar films, but it should not be beyond the ingenuity of those who combine organic chemistry with histological magic to produce multi-coloured electrophoretic strips. A 3-dimensional presentation may confidently be expected.

OBSTETRIC ACUTE YELLOW ATROPHY

THE name "obstetric acute yellow atrophy" was first used by Sheehan[1] in 1940 to describe a condition found at necropsy in 6 patients out of a series of 400 maternal deaths. The clinical features were those of acute yellow atrophy of the liver—namely, vomiting, epigastric pain, jaundice, mental disturbance, coma, and death. The absence of liver-cell necrosis, however, was a conspicuous feature. The most striking histological abnormality in all 6 cases was severe fatty infiltration of an unusual kind; the affected cells were distended with fine fatty droplets which showed no tendency to form the large globules commonly found in fatty infiltration of the liver. Only a narrow rim of cells around the portal tracts looked normal. Despite the very severe involvement of the affected cells, nuclear changes were insignificant and inflammatory reaction absent or slight.

Between 1940 and 1955 only 7 more cases of this kind were reported, but recently Ober and Le Compte[2] have given 3 further examples. These were clinically indistinguishable from fulminant infective hepatitis, and the final diagnosis in each case was made only at post-mortem examination. The histological changes conformed closely to the original description by Sheehan. A remarkable feature of the cases so far described is the smallness of the liver (800–900 g.) despite the absence of histologically recognisable necrosis. As the remaining liver cells were obviously enlarged by their abnormal fat content, the true loss of hepatic substance was even greater than the weight suggests. Since the size of the individual lobules seemed normal, each lobule must have contained fewer than its normal complement of cells. It is remarkable that so great a loss of liver cells can take place in so short a time without leaving a more obvious inflammatory reaction.

As with other manifestations of pregnancy toxæmia, the greatest difficulty is to find the cause. None of the known exogenous causes of severe fatty infiltration seems to be involved, and there was no history of nutritional deficiency, alcoholism, or exposure to hepatotoxic agents. In the absence of any such satisfactory explanation, it must be concluded that endogenous factors are chiefly responsible. Hormonal imbalance, although more often the result than the cause of liver disorder, can at least in experimental animals lead to severe fatty infiltration: Graef et al.,[3] for example, have shown that such a change is often found in hypophysectomised dogs. Although nothing in the history or clinical features of these cases indicated a hormonal upset as profound as that, some less drastic hormonal disturbance may be responsible for the fatty infiltration. Much severer grades of fatty infiltration, however, occur both in man and animals without severe hepatic insufficiency. The problems presented, therefore, by this group of cases concern not only the cause of the fatty change but the associated loss of hepatic tissue and the almost invariably fatal hepatic failure.

Most of these obstetric cases showed a fatty infiltration of the proximal convoluted tubules of the kidney, as which it was immersed, as though this episode had a universal validity for every case of neurological disaster after spinal anæsthesia He assures us also that he has first-hand information (of some presumably unpublished experiments) that such a carbolic solution as was allegedly responsible for paraplegia in two cases recently the subject of a High Court action, when injected intrathecally into "higher animals," produces the lesions believed to exist in these two cases

---

[1] Uriel, J., Grabar, P. *Ann. Inst. Pasteur*, 1956, 90, 427.

[1] Sheehan, H. L. *J. Obstet. Gynæc., Brit. Emp.* 1940, 47, 49.
[2] Ober, W. B., Le Compte, P. M. *Amer. J. Med.* 1955, 19, 743.
[3] Graef, I., Negrin, J., Page, I. H. *Amer. J. Path.* 1944, 20, 823.

He does not give us any details of the clinical course or nature of the symptoms in the experiments he refers to, and without this information his reference is meaningless The point is important since carbolic acid is a corrosive poison with immediate destructive effects upon living tissues That, injected intrathecally, it should lead not to immediate and striking symptoms, but only—as is characteristic of paraplegia following spinal anæsthesia—to a symptom-free latent period of hours or days and then to a subacutely developing syndrome over further days or even weeks, is something I find no grounds for believing

Yet in the cases referred to, this is what the court was invited to believe, and also that it was negligent in an anæsthetist who, using a then accepted method of sterilising his ampoules, did not see in them hypothetical and invisible cracks

In the event, the court accepted the first plea, which was incompatible only with toxicology, but rejected the second which was contrary to common sense

We must regret that Sir Robert Macintosh still seeks to hide the very serious nature of this problem in his invisible cracks, which in fact do not hide it, for all the evidence indicates that there is some special risk inherent in spinal anæsthesia

To maintain there is none such, means that whenever a neurological disaster follows spinal anæsthesia—and there is no reason to think that they will not recur from time to time—the unfortunate anæsthetist involved lies open to a charge of negligence In the present attitude of the public, a scapegoat will be sought, and if it be authoritatively held that the method properly used is without special risk, patients and anæsthetists will be exposed to dangers from which they should be protected

Anæsthetists might well give themselves to some research upon this matter, since a naïve optimism is not a substitute for knowledge

London W 1 F M R WALSHE

ACUTE AND LATENT PORPHYRIA

SIR,—We can support the opinion of Dr Whittaker and Mr Whitehead, in their interesting paper of April 28, that acute porphyria is more common than is generally realised We have encountered five new cases [1] in two years from a population of approximately 300,000, and almost certainly many remain undiagnosed

One of our patients, with paralysis had taken butobarbitone (Soneryl) for the first time just before the onset of the illness and she was inadvertently given the same drug again later, the abdominal pain returned for a day or so but there were no further neurological developments and she recovered

As regards the pathogenesis we suggested that there seems to be a sudden and probably widespread arterial disturbance—perhaps a kind of allergic vasculitis and curiously reminiscent in some respects of polyarteritis nodosa—operating in those with an inherited error of pyrrole metabolism, drugs precipitate this in some cases but in many no causal factor can be found

C E ASTLEY
Middlesbrough A ALUN WILLIAMS

SIR,—We agree with Dr Pathy (May 12) that barbiturates can occasionally precipitate an attack of acute porphyria, one patient under our care was given barbiturate by her practitioner for the relief of insomnia and this induced an attack of acute porphyria We regret that this point was not made clear in our article

Our special interest in the relationship between the neurological complications of acute porphyria and the administration of barbiturates arose from a personal communication from Dr A Goldberg, who drew our attention to Waldenstrom's [1] original observation that barbiturates might precipitate neurological manifestations in patients who might otherwise suffer only from the abdominal symptoms of the disease Goldberg and Rimington [2] develop this theory experimentally, and we trust that they will soon elucidate further the role of barbiturates in acute and latent porphyria

S R F WHITTAKER
Warwick Hospital T P WHITEHEAD

ALDOSTERONE

SIR,—We read your annotation last week with great interest There can be no disagreement with the main conclusion that at present diagnosis and management of primary aldosteronism must rest on clinical findings and metabolic disturbances without depending on the measurement of the hormone in urine or blood However, in the annotation there are certain inaccuracies of fact and emphasis which we feel, if ignored, would tend to delay understanding of the condition

In our experience, the yield of free aldosterone from urine is increased *10 to 30 fold* by hydrolysis at pH 1 not threefold as you quote one of us as saying

The main problem in the study of cases of primary aldosteronism would appear to be that in two examples investigated in detail—that reported by Dr Chalmers and his colleagues (Jan 21) and that described by Dr M D Milne at the Royal Society of Medicine on April 25—the urinary excretion of aldosterone, as measured by our group and Dr G T Mills respectively, although raised above the normal mean value is almost within the range of values for twenty healthy subjects In contrast, certain cases of secondary aldosteronism excrete the hormone in much greater amounts The following possible reasons for this were investigated in the case reported by Chalmers et al

1 That renal excretion or mode of conjugation of the hormone was abnormal However, the concentration of free compound in blood and the ratio of free to conjugated aldosterone in urine was not found to be outside the normal range This explanation, therefore, seems unlikely, as does the advanced in your annotation—that the conjugate may not have been hydrolysed This latter hypothesis would imply the presence of an inhibitor of pH 1 hydrolysis in the urine of cases of primary aldosteronism There is no evidence for this, and in any case the values of free aldosterone in blood and urine were not greatly raised

2 That the condition was due to another adrenal compound However the urine from the case of Chalmers et al was extensively fractioned by partition column chromatography under conditions which would lead to little loss of most neutral steroids The fractions were then bio-assayed with respect to their effect on the urinary Na/K or Na or K excretion of adrenalectomised rats No activity was found other than in the fractions containing aldosterone There is thus as yet no evidence for the existence of such a cortico

3 A recent publication by Luetscher,[3] which is supported by the results of the analysis of rat adrenal venous blood by Singer and Stack-Dunne,[4] reports that normal humans depleted of potassium with plasma potassium concentrations of 1 5–2 5 m eq per litre, show markedly depressed excretion of aldosterone This raises the question as to whether subjects with normal intake and plasma values of electrolytes are the appropriate controls for cases of primary aldosteronism These results indicate that cases of potassium losing nephritis without adrenal tumour showing low potassium and normal

aspects of a case were often brought to light and in general the staff obtained a new understanding and insight which they were then able to apply in dealing with other patients in their care Mackenzie's paper shows that this way of working is a valuable advance in preventive mental health and a pointer to further progress

ELECTROLYTES AND THE ELECTROCARDIOGRAM

THE importance of the electrocardiogram (E C G) in the detection of disorders of electrolyte balance is now generally accepted The process of ventricular activation is influenced by the ionic concentration of the extracellular fluid bathing the cells of the myocardium, and also by local electrolyte changes in the cells themselves There is generally a fair agreement between the serum concentration of certain electrolytes and the development of electrocardiographic changes The electrolytes which produce changes in the E C G are potassium and calcium Alterations in serum sodium levels may also indirectly produce E C G abnormalities by inducing acid-base imbalance and altering the potassium sodium ratio in the extracellular compartment

Electrocardiographic changes due to a low serum-calcium develop when the level falls below 7–8 mg per 100 ml There is an increase in the iso electric line between the Q R S and T deflections, the T wave is unaffected, but the duration of systole (Q–T interval) is greatly prolonged [1] By contrast, hypercalcæmia shortens the Q–T interval, virtually abolishing the ST segment [2] Hypokalæmia produces depression of the ST segment, flattening of the T wave, and large U waves [1–3] Conduction defects and arrhythmias are common The Q–T interval is prolonged but often difficult or impossible to measure because of the disappearance of the T wave into the U wave [4] By contrast, hyperkalæmia is associated with greatly augmented positive T waves, and conduction defects in severe cases

Bellet [2] has closely studied the E C G changes in electrolyte imbalance He points out that the prolonged Q–T interval in hypocalcæmia can be brought back to normal by the intravenous administration of calcium, and that, although the patterns of low calcium and low potassium states are usually strikingly different, combined deficiencies of the two electrolytes produce atypical pictures He has examined the E C G s of 125 patients with hypokalæmia from various causes and has described four patterns Pattern I consisted of ST-segment depression and a prominent U wave, pattern II included various degrees of T-wave inversion, associated with prolongation of the Q–T interval, and a prominent U wave, and patterns III and IV consisted of positive T waves of various shapes followed by one or more U waves The diagnostic E C G appearances were most common at levels of serum-potassium below 3 0 m eq per litre Measurements of intracellular and extracellular potassium showed that the E C G pattern correlated better with the extracellular than with intracellular levels But there was not always close agreement between serum-potassium and the E C G , because of variations in the normal range, and because of other factors, such as the administration of digitalis, which shortens the Q–T interval and distorts the ST segment By contrast, cardiac ischæmia, subendocardial infarction, and myocarditis could produce E C G changes similar to those seen in hypokalæmia, while potassium intoxication has been shown to produce currents of injury resembling acute cardiac infarction or pericarditis [5] Bellet [2] has also shown that hyperkalæmia may cause the inverted T waves of myocardial infarction to become deeper, and Sharpey Schafer [6] noted the same result after giving potassium by mouth to patients with inverted T waves from the same cause When the T-wave inversion was due to ventricular preponderance, however, potassium caused the T waves to become upright

Bellet has described four stages in the development of the E C G signs of hyperkalæmia in the dog Stages 1 and 2 consisted of elevation of the T wave with narrowing of the base, and cardiac irregularity due to sino auricular block (serum potassium 6–9 m eq per litre) In stage 3 the ventricular complexes were widened, and the ventricular rate slow (serum potassium 10–13 m eq per litre) Stage 4 showed slow idioventricular rhythm, and further widening of the Q R S (serum potassium 14–18 m eq per litre) The cause of death was usually ventricular standstill, but occasionally fibrillation (at a level of 16–18 m eq) in the normal dog The stages in man were very similar, but less well demonstrated The effects of hyperkalæmia on the E C G of cardiac infarction were variable, either causing the T wave to become larger and further inverted or to revert to a positive deflection In patients with subendocardial ischæmia, potassium produced a diphasic T wave which was not typical of hyperkalæmia Bellet concludes that the electrocardiographic detection of hyperkalæmia is difficult in the early stages Certainly augmented positive T waves in precordial leads can result from posterior infarction and pericarditis, and may be the prelude to an anterior ischæmic episode [7]

Careful attention to the changes in serial electrocardiograms can yield valuable information about electrolyte disorders, but interpretation must take account of the many other factors which may obscure or counterfeit specific changes

VASCULAR HEADACHE

IT is now well established that the headache of migraine is usually due to distension of arteries, probably both intercranially and extracranially But, by their quality and accompanying symptoms many headaches which do not form part of a true migraine syndrome seem to be vascular in origin Indeed, adequate investigation of headaches of uncertain cause now includes full exploration of the response to vasomotor drugs, both constrictor and dilator By this means it is often possible to reproduce the spontaneously occurring headache and so plan rational treatment Wolff [8] and his colleagues have done a great deal in the past few years to clarify these vascular headaches One of their many contributions is to the technique of recording changes in the extracranial arteries They have designed an instrument,[9] essentially similar to Mackenzie's polygraph, for recording the arterial pulse-wave via an electronic amplifying system on a direct ink-writer This device clearly demonstrates changes in the pulse contour in a variety of spontaneous headaches and in those induced by vasomotor drugs The recorder can be easily applied to the temporal arteries and its branches and to the occipital vessels Moreover, simultaneous bilateral recording can help to elucidate the mechanism of unilateral headaches Such investigations have confirmed that changes in vascular tone and calibre—both distension and constriction—may be responsible for headaches Tunis [10] has given further illustrations of the application of this method to the study of headache and of the effect of allegedly vasomotor drugs There is no doubt that it provides objective evidence of changes in a field where subjective symptoms are often particularly difficult to assess

PERFORATED ACUTE AND CHRONIC PEPTIC ULCER

SIR,—We would like to reply to some of the points raised by your correspondents on this subject Like Mr Moore (April 28) we practise vigorous resuscitation measures in patients with grave peritonitis and include among these drainage of the peritoneal cavity at the earliest practicable moment Mr Moore, however, doubts our description of 7 patients as "moribund" before treatment and implies that more vigorous management might have saved some of them Mr Gilmour (May 5) considers that consecutive admissions of cases of perforation to his beds on his receiving day constitute an unselected series of cases comparable to our own We therefore put forward brief descriptions of our 7 moribund cases to illustrate our attitude to these problems

1 Man, aged 67 perforated duodenal ulcer, blood pressure unrecordable on admission Dextran and blood transfusion, peritoneum drained under local anæsthetic Died within 24 hours of admission

2 Man, aged 63 perforated duodenal ulcer, very emaciated, chronic bronchitis, œdema of ankles, and bedsores Immediate response was good but collapsed and died 16 hours after admission

3 Woman, aged 77 perforated gastric ulcer, blind and deaf, bedridden for 15 years Became unconscious soon after admission and made no response to treatment Necropsy showed pulmonary embolus in addition to peritonitis

4 Man, aged 83 perforated carcinoma of the stomach with secondaries

The next three patients were all admitted to the medical wards

5 Man, aged 74 admitted with uræmia and bleeding duodenal ulcer, perforated after admission Perforation did well with conservative treatment but patient died after five days from uræmia, due to pyelonephritis in only functioning kidney

6 Man, aged 69 admitted with severe bleeding from duodenal ulcer and gross anæmia While he was being resuscitated the ulcer perforated In spite of vigorous treatment he never recovered sufficiently to undergo operation

7 Man, aged 77 admitted as a case of collapse and died in a few hours Diagnosis of perforated duodenal ulcer made at necropsy

We hope that Mr Moore will admit that "moribund" is not an exaggerated description of these cases We hope that Mr Gilmour will agree that our mortality figures include more deaths than those in "cases admitted to the beds of a surgeon on his receiving day" The last 3 cases would not have been included on Mr Gilmour's definition of an unselected series nor would 2 at least have been likely to appear under the main heading of "perforations" in the lists of a hospital records officer We find a great difference between mortality in that group of cases which find admission to surgical wards and the total admissions to the hospital collected *as the cases arise* as a matter of special interest Avery Jones found the same discrepancy, with less than half the mortality in the operated cases

Mr Downie (May 19) asks what proof exists that our 200 cases were in fact perforations 75% of the cases showed gas under the diaphragm on radiography, and we have regarded that as proof The incidence of intraperitoneal gas is roughly the same as in published figures of operated series where the diagnosis was confirmed at operation We feel, therefore, that our clinical diagnoses in the 25% without gas are not far wrong apart from the collected group of errors we have described There is, of course no proof, but cases have only been accepted as perforations with the full distinctive clinical picture the series does not include doubtful "leaks" or painful exacerbations of the ulcer The question is of course an academic one Our claim is that within the conditions set out in our paper the patients whom we diagnose as suffering from perforated ulcers do remarkably well if they have only a short history of dyspepsia, but are well enough—like the sutured cases in other hospitals—if they have suffered from indigestion for years

We do not wish to enter into a discussion on the place of immediate partial gastrectomy in the treatment of perforations Our experience teaches us that no sort of operation has any place in perforated *acute ulcer* but that neither suture nor aspiration is completely satisfactory, in the long view, in cases of perforated *chronic* ulcer Where it is feasible, we believe partial gastrectomy to be the treatment of choice for perforated chronic ulcer Nevertheless, if the condition of the patient precludes partial gastrectomy, operation merely to close the perforation offers no advantages where the stomach can be kept empty by aspiration

London Hospital, E 1

HERMON TAYLOR
RICHARD P WARREN

SMOKING

SIR,—In connection with cancer of the lung and cigarette smoking there is much talk of alleged "carcinogenic factors" in tobacco smoke Research is going on in the hope of finding such factors, and—presumably—eliminating them from the tobacco so that people can go on smoking (and coughing their heads off) immune from the danger of bronchial carcinoma

Perhaps the *coughing* is the clue to the riddle? The heavy cigarette smoker who presents with cancer of the lung has had "a smoker's cough" for years—and an inflamed, irritated respiratory tract, the lining cells of which are under a constant stimulus to replace themselves with undamaged cells It is not to be wondered at if some fine day the replacement process shows signs of wear and tear and carcinoma cells are produced

If this theory of irritation is correct the search for presumed "carcinogenic factors" in tobacco is superfluous Cancer of the lung could result equally from smoking brown paper or cabbage leaves

In pipe-smoking there is conspicuously less irritation of the throat, less coughing, and less carcinoma of the bronchus

London, W 1

J A BRUCE YOUNG

HOME CONFINEMENT

SIR,—I should like to mention another argument in favour of home confinement, or better still return home after completion of labour as in the scheme suggested by Dr Sluglett and Dr Walker (May 12) Much has recently been written about the effects of maternal deprivation on young children[1] A young child needs to have and to *feel it has* persistent parental affection and protection to give it emotional security[2] How disturbing it must be for the firstborn to be separated from his mother while she goes into maternity hospital and on her return to be presented with a mewling infant who monopolises much of her time

It appears that most children survive the trauma with little reaction except jealousy of the newcomer and "difficult" behaviour, but it is conceivable that harm might be done and that from a mental health point of view the increasing number of hospital confinements may not be a desirable cultural pattern

Cardiff

JULIA FOREMAN

SIR,—I am sure that all G P obstetricians will welcome the inquiry into the maternity services which has been set up as a result of the findings of the Guillebaud Committee's report and will await the emergence of a comprehensive and unified midwifery service with patience

2 Edelston H Earliest Stages of Delinquency Edinburgh 1952

TABLE IV—PREVALENCE OF BEDWETTING BY SOCIAL GROUP (REGULAR BEDWETTERS ONLY)

Social group	Percentage regularly wet at age (yr.)			Wet throughout the period (%)*	No. of children (wet and dry)†
	4¼	6	7¾		
Professional and salaried	2·21	1·95	1·68	2·07	768
Black-coated	3·27	2·72	1·90	2·08	1102
Manual	3·64	3·81	3·47	2·84	1757
Agricultural	2·74	2·74	1·68	1·99	474

* These percentages include children wet regularly at some periods and occasionally at others.

† 193 children had fathers who were self-employed or engaged in miscellaneous occupations.

was 12·2% at 4¼ years, falling to 10·3% at 6 years and 7·3% at 7¾ years. The corresponding figures for regular bedwetters were 3·5%, 3·6%, and 2·9%. The proportion consistently wet throughout the period was 3·2%.

Since regular bedwetters give the greatest trouble to their parents and their doctors we have considered them alone in tables III–VI.

Family Size

The usual impression that bedwetting is more common among children from larger families is only partly borne out by the present study. Table III shows the proportion of bedwetters who were firstborn and later-born children.

When both sexes are taken together there is no significantly greater prevalence of bedwetting among the later-born, although at both 4¼ and 6 years there is a slight but not significant excess of bedwetters among them. When sex also is considered this excess is seen to be greater for the boys than for the girls.[6]

TABLE V—SEX DIFFERENCES IN BEDWETTING BY SOCIAL GROUP*

—	Percentage regularly wet at age (yr.)			No. of children (wet and dry)
	4¼	6	7¾	
Non-manual workers				
Male	3·81	3·41	2·51	897
Female	1·71	1·26	1·03	873
Manual workers†				
Male	3·83	4·27	4·05	913
Female	3·43	3·43	2·84	844

* Comparing males and females among non-manual workers: $\chi^2 = 21·46$, $n = 3$, $P<0·001$.
Comparing males and females among manual workers: $\chi^2 = 2·93$, $n = 3$, $0·5>P>0·3$.

† Excluding agricultural workers.

The birth of a younger child has been regarded by some as a factor in the ætiology of bedwetting. This view receives no firm support from the present evidence. The prevalence of regular bedwetting among children aged 4¼ years was 3·7% when there was a younger sib and 2·9% when there was none—a difference in the expected direction but of no statistical significance.

Bedwetting among Sibs

In 1953 the mothers of all our survey children were asked to give details of any of their other children who had wetted their beds at night even if they had later become dry. The answers relate to 3536 sibs aged from 5 years to 14 years 11 months in 1953.[7]

Of the 264 sibs of regularly wet survey children 28 (10·6%) had a history of bedwetting and of the 3272 sibs of dry or occasionally wet survey children 189 (5·8%) had a history of bedwetting.[8]

In addition 480 sibs occasionally wetted their beds, of whom 9·6% had been bedwetters—a proportion that is about twice as great as that among the 2794 sibs of entirely dry children (5·1%).[9]

Thus it appears that the familial element is equal in regular bedwetters and in occasional bedwetters. This does not necessarily imply that there is a genetic basis for bedwetting; it could equally be explained by a common pattern of upbringing.

Social Group

It was expected, from the evacuation experiences of the 1939–45 war (Titmuss 1950, Women's Group on Public Welfare 1943), that there would be a social gradient in bedwetting, and this was found in the present survey (see table IV).

TABLE VI—PROGRESS OF CHILDREN GIVEN DIFFERENT TYPES OF TREATMENT FOR BEDWETTING

—	Type of treatment given (as reported at 6 yr.)			No treatment†
	Clinic	Reward or punishment	Other active measures	
No. regularly wet at 6 yr.	41	67	32	26
Percentage dry by 7¾ yr.	19·5	20·9	31·3	57·7
Percentage improved*	24·4	28·4	28·1	11·5
Percentage unchanged	56·1	50·7	40·6	30·8

* i.e., only occasionally wet at 7¾ yr.

† No treatment was admitted by the mother, but it is likely that all the parents tried various methods at different times even if no consistent method was used.

The lowest incidence of bedwetting was among children of the relatively prosperous professional and salaried groups and among the children of agricultural workers. The greatest prevalence was among the manual workers, whereas the children of black-coated workers occupied an intermediate position, being nearer the manual at 4¼ years and nearer the salaried at 7¾ years. The gap between the social groups widened with increasing age and was only significant at 7¾ years.[10]

The proportion of children wet throughout the period was similar in each social group, and the excessive number of bedwetters in the poorer groups was apparently made up of children becoming wet for relatively short periods.

We have already remarked on the high prevalence of bedwetting among boys. This sex difference was largest and only significant in the professional and black-coated groups, and part of the unfavourable position of the children of manual workers seems to be explained by the high prevalence of bedwetting among the girls (see table V).

Geographical

There were no significant differences in the proportion of children reported as bedwetters for the various regions of England; nor were there any significant differences

---

[6] The excess among later-born boys is significant at 6 years: $\chi^2 = 4·773$, $n = 1$, $0·03>P>0·02$.

[7] Owing to certain sorting difficulties, sibs under 5 were excluded from the following analysis. Sibs of 15 years and over were also excluded because many of them had left home and thus had made it impossible to define with any certainty the complete population of these older children.

[8] Comparing these two groups of sibs: $\chi^2 = 9·891$, $n = 1$, $P<0·01$.

[9] Comparing these two groups of sibs: $\chi^2 = 15·332$, $n = 1$, $P<0·001$.

[10] At 4¼ years $\chi^2 = 3·886$, $n = 3$, $0·3>P>0·2$.
At 6 years $\chi^2 = 7·144$, $n = 3$, $0·1>P>0·05$.
At 7¾ years $\chi^2 = 11·685$, $n = 3$, $P<0·01$.
When non-manual workers are compared with manual workers, significant differences are found in each year.

Obituary

JOHN DEMPSTER FRASER

T D, M B Glasg, F R F P S, D O M S

Dr J D Fraser, who died while he was giving expert evidence in court on May 21, had been surgeon to the Glasgow Eye Infirmary for only a short time but it was long enough for him to win the friendship of his colleagues and the admiration and respect of his patients He was born in 1913, and educated at Hillhead High School and the University of Glasgow After graduating M B with honours in 1936 he held resident appointments under Sir John McNee, Prof A J Ballantyne and Mr Roy Young His postgraduate training was interrupted when he was mobilised as a regimental medical officer to the 6th Battalion of the Highland Light Infantry, but in December, 1939 he was posted to the China Command as an ophthalmic specialist As a prisoner-of-war in Hong-Kong he was allowed to continue his work as the ophthalmic specialist to the British Military Hospital until the end of hostilities For his war service he was mentioned in despatches and in *1946* he read a paper to the Ophthalmological Society of the United Kingdom on the ocular manifestations associated with malnutrition, based upon his personal observations carried out in the military internment camps in Hong-Kong

After the war he resumed his work as a clinical assistant in the Glasgow Eye Infirmary and in the university eye department at the Western Infirmary When the Ophthalmological Society of the United Kingdom met in Glasgow under the presidency of Professor Ballantyne, Fraser acted as local secretary and impressed the members by his enthusiasm and efficiency His flair for this kind of work developed, and he became the Glasgow secretary of the Scottish Ophthalmological Club His interests within the specialty lay in pathology and neurology For ten years he worked as ophthalmologist to the neurosurgical unit at Killearn Hospital

"In that position," writes J S , " he gained an authoritative knowledge of the neurology of the eye which can rarely have been equalled by one so young Not only the quality of his advice but also the confidence with which he gave it made his neurological colleagues rely on him to an ever greater extent Although the number of patients seen by him in consultation grew week by week not only did he investigate them all most carefully but he got to know each patient as a human being with a job and a family Weeks and months later he might recall the details of an optic fundus and remember where the man lived and worked and how many children he had We shall miss his counsel, his human warmth his great practical common sense and his humour "

As W J B R says, " his loss is a most serious one not only to Glasgow and the West of Scotland but to a wider medical public which was beginning to appreciate his calibre He spoke well and with assurance at a meeting in London the month before he died His work was of the highest quality and he possessed great manual dexterity."

Dr Fraser is survived by his wife, a daughter, and a son

GUSTAV HERRNHEISER

M D Prague

Dr Herrnheiser, consultant radiologist to the Connaught Hospital London, and a former professor of the German University of Prague, died on May 13

He was born in 1890 in Prague, and studied medicine at the German University there, and at Munich After graduating M D in 1914 he spent seven years in postgraduate work in Prague at the morbid anatomy department under Ghon and at the department of internal medicine under Jaksch In 1920 he joined the radiological department under Holzknecht in Vienna Five years later he returned to Prague as *Dozent* in radiology to the German University In 1931 he was appointed to the chair of radiology His early work included investigations on the anatomy of the blood-vessels of the lung but later his main interest was in radiological diagnosis of diseases of the chest and gastro-intestinal tract

In 1939 political events forced him to leave Pra where he had lived and worked for the best part of l life, and where he had built up the X-ray departm at the university clinic He went first to Palest where he became chief radiologist to the Hadass Hospital, Tel-Aviv, an appointment which he held u 1942 when he left for Egypt to become chief radiolo to the King Fuad Hospital and the Jewish Hospital i Alexandria He settled in this country in 1948 F the first time after many years he felt at peace agai writes M E G , 'and England became a second ho to him one which he loved and where he was happ once more He soon became active again, and in a ve short time made many new friends He was respect by all who met him, and realised his qualities h sincerity and deep knowledge, his innate modesty a unceasing search for the truth

Professor Herrnheiser leaves a wife and two daughte

Dr J M D OLMSTED a former professor of phys logy at the universities of Toronto and California h died at the age of 70 He shared in the research whi led to the discovery of insulin, and he was a co-edit of several editions of *Macleod's Physiology in Mode Medicine* He was also interested in the history of h specialty and had published monographs on Clau Bernard (1938) and on François Magendie (1945)

DEATHS

REVELL —On May 26 following an operation at University College Hospital London Rowan William Revell M D D P H [illegible] officer of health for [illegible] dearly beloved husband of [illegible] Revell pulmonary tuberculosis, as suggested by Early (1950), who estimated that about 2·5% of the regional mental hospital beds should be formed into one tuberculosis unit, the optimal size of which would probably be about 150 beds.

Summary

Tuberculin and radiographic surveys were made in an institution for mentally defectives.

3·66% of the patients were found to have significant pulmonary tuberculosis, half of which was considered to be active.

These figures agree closely with published surveys made in similar institutions.

Suggestions are made for the control of tuberculosis in mental institutions.

Thanks are due to Dr Reginald Bailey, physician-superintendent, Gogarburn Hospital, for his willing cooperation, which made this survey possible; Dr P. W. Tait, medical director, mass-radiography unit; and Dr A. T. Wallace for bacteriological investigations.

GENERAL MEDICAL COUNCIL

At the opening of the council's 192nd session on May 29 Sir DAVID CAMPBELL, the president, remarked that in the recent elections of direct representatives of the medical profession to the council 41% of the electorate in England had voted. It was a matter of concern that 2380 (4½%) of the voting papers issued in the English election were returned as dead letters, with the consequent disfranchisement of the practitioners to whom they were sent. Apparently the tendency of addresses to become inaccurate still moves nearly as fast as the process of correction. In the long run a high level of accuracy would be achieved and maintained only by the cooperation of every member of the profession in making sure that his registered address was one at which letters would reach him.

The executive committee had lately decided to recognise the degrees of the University of Baroda in respect of the Medical College, Baroda; the degrees of the University of Nagpur in respect of the Medical College, Nagpur; the degrees of the University of Rajputana in respect of the Sawai Man Singh Medical College, Jaipur; and the diploma of membership of the State Medical Faculty of West Bengal in respect of persons who had studied at a medical college affiliated to the University of Calcutta.

At its last session the council had adopted new rules as to courses of study and examinations for diplomas in public health. These rules, superseding those adopted in 1945, made no provision for a certificate in public health but in other respects did not differ substantially from the previous rules. The new rules would come into operation on Oct. 1, 1956.

A Bill for consolidating the Medical Acts and statutory provisions passed between 1858 and 1950, of which there were more than twenty, was now in an advanced state of preparation, and was indeed likely to be presented in the House of Lords almost at once.

The President referred to an appeal by a practitioner to the Judicial Committee of the Privy Council against a decision by the Medical Disciplinary Committee to erase his name *from the Register*.[1]

"The Disciplinary Committee will . . . no doubt wish to consider at an early date the desirability of widening one or more of their existing rules in the manner which their Lordships have been so good as to indicate. I must add, however, that under section 16 of the Medical Act, 1950, it will be necessary for the committee to consult with certain outside bodies before amending the rules."

On July 1, when the Dentists Act, 1956, would come into operation, the responsibilities of the council in regard to dentistry would cease. These had lasted for 78 years, and it was hard nowadays to picture the situation as it was when they began. On the one hand dental surgery was historically a branch of surgery; on the other there were many persons at that time who with a limited practical training were occupied with dentistry as a trade or craft rather than as a profession. The first Dentists Register published by the council in 1879 contained the names of 483 licentiates, and no graduates, in dental surgery, together with 4806 persons who on their own declaration were stated to be engaged in the bona fide practice of dentistry. The 1922 Register, the last Dentists Register published by the council, contained the names of 1768 licentiates or graduates in dental surgery. Today there were 15,895 names on the Register, including 12,521 licentiates or graduates. At the end of its long period of trusteeship the council handed over its remaining responsibilities in the dental field with the greatest good will to the new General Dental Council. The G.M.C. would not lose all contact with dental education and examinations, for under the new Act it was to nominate six of its number to act and vote for those particular purposes as members of the General Dental Council.

Public Health

TRACING A TYPHOID CARRIER
BY MEANS OF SEWER SWABS

F. BIRD HOBBS
B.A., M.D. Camb., M.R.C.P., D.P.H.
MEDICAL OFFICER OF HEALTH, FARNHAM U.D.C.

On Jan. 10, 1955, a boy aged 7 years was admitted to the isolation hospital with a diagnosis of ? encephalitis. He had been taken ill five days previously with a sore throat and a rash and was at first thought to have scarlet fever. He had a swinging temperature up to 105°F and was very drowsy.

During the next seventeen days this high swinging temperature continued and he was extremely ill. His motions were loose and incontinent, and this was at first thought to be due to the aureomycin with which he was being treated. Blood culture, Paul Bunnell, and other tests were negative, and it was not until Jan. 22 that the Widal test was found to be positive and typhoid bacilli were found in the stools, and the case was first notified to me.

On investigating, I found that the patient had not been out of Farnham except to visit Harringay Circus on the day previous to the onset of the illness. He had eaten no ice cream, shell fish, watercress, &c., and since the other inmates of the house were quite well, food did not appear to be the source of infection. His mother, however, told me that he, together with two other boys, had been playing in a field where there had been an overflow of sewage during the recent heavy storms, and that he had come home with his boots covered in sewage. This seemed to be a very likely source of infection, so I decided to take samples of sewage for bacteriological examination.

---

[1] See *Lancet*, May 5, 1956, p. 641.

to exact sciences than does medicine But there is still hope, I think, for the student who cannot think logically when he first enters the hospital wards, for many such eventually become surprisingly good doctors In fact the scientific method of thought can be developed in the wards no less than in the laboratory I would therefore plead that preclinical teachers should resist the temptation to press for the exact maintenance (or even extension) of their present share of the student's time and energies

The third objective is the acquisition of *empirical knowledge* Only as experience grows will the student develop clinical judgment

Processes of Learning and Techniques of Teaching

The student must learn to observe and reason and must acquire empirical knowledge Observation he can learn only by long practice this requires the use of the senses but no great mental effort The ability to reason, on the other hand, can be gained only by using the mind These are two entirely different processes of learning Furthermore, it is not easy to combine the two, and it can be very confusing to try to do so, particularly at first It follows that the arrangement of studies must facilitate learning by enabling the student, so far as possible, to use one process at a time Each is assisted by different techniques of teaching, one transmitting information passively and the other activating thought Thus the technique of teaching should always be relevant to the process of learning This is, in fact, vital to the successful study of medicine which contains so much factual material, for if timing is wrong, or the wrong methods of teaching are used, the student has little alternative but to commit the facts to memory without understanding This is more likely to happen in medicine than in other subjects because medicine includes so much that is not yet understood by anyone, and where knowledge is empirical it can be acquired only by memory, aided by experience Too early exposure of the student to random experience is an incentive to practise memorisation and discourages his efforts to learn by understanding Hence unlimited vocational experience and teaching should be restricted to the later stages of his education

No one, however, can think in a vacuum, and learning the method of rational thought requires some knowledge to start with In the earliest stages of his education, therefore, the student must be given selected facts It is essential that his mind should work upon orderly problems rather than chaos He will be helped by systematising the material which he must learn, and in the early years, some integration of subjects is necessary for this reason His experience of clinical problems—i e, of patients—should, likewise be systematic at first Recognition of this, and action to ensure it, is of the utmost importance I do not believe this is fully understood

Techniques of teaching require further experiment and research To standardise them would certainly be a mistake for they are much affected by environment and by the widely differing attitudes of students Thus there is a great need for individual selection, by and for each student, of the most appropriate technique, and our present educational system fails to recognise or cater for this need We have already at our disposal a considerable array of methods of proved value What is wanted is a closer study of their efficacy and especially of their application to different stages of medical education We have the didactic lecture, the clinical theatre demonstration, traditional outpatient teaching, bedside demonstration, teaching in the wards to a small group, the individual tutorial with or without patients the discussion group, the clinical pathological conference in these, according to circumstances and the habits of the teacher, teaching predominates, or there is mutual interchange of ideas or the student may take an active part Then we have practical duties—the medical clerkship, the apprenticeship in the outpatient clinic Then again, the stude may learn for himself by extracting knowledge fr textbooks and original papers, or by analysing ca records, or writing essays, or doing a piece of resea All these are learning techniques which need to b arranged more deliberately to serve a definite education purpose at each stage of the educational plan Onl experiment with different methods, can enable us t arrive at the best possible arrangement

An Educational Plan

So little is known of the processes of learning and little have the techniques of teaching been studie that it is impossible to claim that, of the several pla on which medical education could be based, any particul one will prove to be the best It is, however, undenia that each must endeavour to ensure that medical educ tion becomes a continuous process of learning, progress by interlocking stages, each with its own education objective and techniques of teaching relevant to i In the light of experience I would favour a sequence stages as follows

The study of the normal
The study of the causes and effects of variation from norma
A short introductory course in clinical method
A period of practice of clinical method—i e, an orde clinical clerkship
A stage of consolidation—designed to combine the stud of special pathology and the systematic study of clinic medicine
A stage of more general experience mainly in the ward by attachment to firms
A stage of special outpatient teaching and of midwife and pædiatrics
A stage of practice under supervision, both in the ou patient department and outside hospital
A stage of responsible practice under supervision—i e the provisional registration appointments

That is the skeleton which I now propose to clothe though very sketchily I must make it plain, however that I am not trying to describe a curriculum I am describing a plan which could become the curriculum in my own medical school (or any other) only if all the teachers required were available at the right time, and all the necessary facilities, both clinical and non clinical could be found Even then, after the plan had been put into effect as a curriculum, it might well prove to be wrong as regards the duration of its stages, or their sequence, or the methods of teaching employed

Study of the Normal

The study of normal would be an *introduction* to anatomy, physiology, biochemistry, and psychology—a systematised and, as far as possible integrated, introduction Such interdepartmental teaching would not be difficult to achieve, and in Birmingham a course of this kind exists, though on a bigger scale Perhaps it integration at staff level, each teacher knowing what his colleagues are teaching, that is most important, and at this level there is usually much more integration in our present preclinical departments than in the clinical field

To illustrate what I mean by introduction, I will take anatomy as an example *The whole body would not* be dissected, and it would be useful to experiment with dissection of the fœtus More detailed study of certain areas of the body would be left to later periods when it could be related to clinical work, for instance, th pelvis would be studied with midwifery It might however, prove sensible to study one system in detail at this early stage, and the central nervous system is the obvious choice—and rewarding because of the ease by which anatomy and physiology can be integrated in this system and their application to clinical medicine demonstrated In helping the student to understand the normal the departments of medicine and surgery would take part

In England Now

A Running Commentary by Peripatetic Correspondents

For many years it has been my lot to stick needles periodically into other people's children—but last week found me at the other end of the needle. I arrived at 9.30 A.M. at a welfare centre in North London with my eight-year-old son and sat in company with a dozen other ladies and their children waiting with identical appointment cards for our first injection against poliomyelitis. It was a curiously assorted gathering, reminding me of hours once spent during a pregnancy at a launderette. Conversation established that the birthdays of all children present fell in March or November. No further confidences were exchanged, because my neighbour asked me in a ringing tone if I were not scared, adding that she nearly hadn't come herself. At once I too experienced unreasonable terror, but glancing at the faces of the elder children and seeing the stony look on my son's, I explained that the know-all to whom I am related by marriage considered us to be in the category of (small) football-pool winners. I got the impression that not even my son believed me, and the evidence of our ears now proved that some of our predecessors behind the closed door shared my neighbour's views.

Soon it was our turn to enter this door and roll up the left sleeve. The injection (most expeditiously performed) was followed by advice to take no violent exercise for a week—no swimming in particular. The first signs of distress now appeared, and my offspring's eyes filled with tears. "No cricket?" asked this little Briton. The lady doctor's voice took on a more strongly Continental note. "Ah, cricket," she said musingly, "cricket is something I do not understand—but not a very violent game, I think."

* * *

"Cambridge should be a man's university" was the creed graduates and undergraduates of my generation held in the 20s. Women had been enfranchised; they had gained equality in all the other British universities, and they should be content. Members of Girton and Newnham attended lectures and were like ordinary undergraduates until they came to the end, when they were allowed to take their degrees by diploma and (lucky beggars) did not have to pay graduation fees. Their chief grievance was that they could not hold university posts.

The crisis came, so we thought, in 1921 when a grace before the senate recommended that women should be admitted to degrees and given representation on the council of the senate. The hackneyed phrase "controversy ran high" was an understatement. Clergymen, who rarely left their parishes, were coming up to vote, and doctors who were supposed to be absolutely opposed to the idea, were travelling in force despite great inconvenience. Such were the rumours founded on hearsay and sometimes not even on that. The great day arrived and 1602 graduates voted. The figures were given from the Senate House: PLACET 694, NON PLACET 908. The crowd, on hearing that the non placets had defeated the grace and kept the women in their place, rushed to Newnham. The gates were closed against us. Tree trunks were quickly collected from nowhere and used as battering rams against the wrought-iron gates. (Vandals rarely know the beauty of the things they mutilate and it was a shock to all of us to find that these gates were of great artistic value.) The authorities had phoned the police, who arrived expeditiously, and the word quickly went round, "The police have drawn their truncheons." It is 35 years ago, but I can still remember doing my right-about turn and sneaking off like a dog with his tail between his legs. Retribution in kind was offered at once, but true retribution came later, and as it came slowly led to conversion.

Marriage, an educated wife, and two daughters as worthy of our university education as my son, have all played a part. So has women graduates' ready acceptance of the responsibilities of educated citizens.

In 1947 women were admitted to full membership of Cambridge University, and equality and equity were achieved, if we except their ineligibility for the office of proctor and esquire bedell. All would now be well if Girton and Newnham could take all the eligible women who want to have a Cambridge University education, but they cannot, and these two colleges and all the men's colleges have tried to remedy this by helping in their divers ways to found a third women's college, New Hall. It will want help from every quarter if it is to become a seat of learning like its Victorian sister colleges, and my hope is that many of my generation who enjoyed their years at Cambridge will help to give more women the benefit of what we all feel Cambridge provides, the best education in the world.

* * *

Wandering round an exhibition of historical documents at Portsmouth the other day I noticed a letter from one John Aylward sending the overseers of the poor of Portsmouth an account for medicines and attendance provided from Nov. 20, 1784, to March 15, 1785, by Edward Hale and John Cotman, two surgeons living at Hambledon. The bill came to £6 [illegible]s. and it is endorsed by the surgeons of the Portsmouth Workhouse as follows: "We have examined the within bill and are of the opinion that forty shillings may be deducted therefrom, with propriety." The charges included 2s. 6d. for "a nervous mixture" and 5s. for "a journey." A second more sympathetic endorsement runs: "We whose names are hereunto subscribed are much astonished to see the signatures of two gentlemen of the Faculty so very improperly placed to this Bill, intimating an Imposition in the Charge, as they are very certain they themselves wd have made it double for so long an attendance even at their next door." Mileage and prescription charges always seem to have been live issues.

* * *

Personally I prefer our Aylesburys wrong side up with a full dish of green peas alongside, so until last year the final quack had been silenced by Christmas. It was only a bid by a farmer neighbour for the future stud services of a particularly fine specimen of English duckhood that saved Sir Francis from a macabre visit to the potting shed. The possible immorality of leaving him alone in the feminist stronghold of the henhouse led to Corluvia's reprieve, and so the winter snows were printed with a double set of deltas. With the coming of spring she disappeared from the garden, and although we suspected a poacher's dirty work Sir Francis remained surprisingly complacent in his isolation. In fact he seemed puffed up with unaccustomed pride. We were getting rather worried about Corluvia until one evening our old bloodhound lumbered up and began breathing heavily into a crevice in the wood pile. A flurry of white shot out. Monitor put his stern between his legs and fled, with a wicked yellow bill snapping dangerously near a tender spot. We took advantage of the chase to investigate the nest. There sure enough were ten warm eggs. Our daily help is a natural pessimist, casting doubt upon the fertility of the clutch. She shook her head: "I've never seen Sir Francis acting like a proper gentleman." But I have attended so many clinical examples of the magic of the waterside meadows in our village that I am putting in five extra rows of peas this year.

* * *

I now have a perfect reply to philistinism. Passing from the room with the French impressionists at the Tate to the last, most modern one of the current exhibition of German painting, we stopped to examine one of the striking large canvases. It was a representation of round, oval, and irregularly shaped splashes of vivid colour and no identifiable message. My wife wondered aloud if our Peter could achieve something like it. This was overheard by a middle-aged, stocky, bearded man who observed with perfect charm: "May I respectfully suggest, Madam, that he tries."

* * *

May I intrude upon the musing of the peripatetic shuftiscopist and, with respect for the sanctity of the wondrous revelations of auscultation to the physician, suggest that we rename the stethoscope, the Accessory Oracle?

Premedical Education and Postgraduate Training

The plan I have outlined for undergraduate medical education depends on what goes before it and what comes after I am certain that a balanced general education and a sound foundation in basic science can be achieved only by relaxation of the excessively high academic standard now demanded for entry into medical schools No authority ought to require more than three subjects to be taken at advanced level, and one of these should be non-scientific

At the other end of undergraduate education postgraduate training must be arranged in continuity, according to the specialty which is to be practised Provisional-registration house appointments are a part of undergraduate education—a period of *responsible* practice under supervision—but they are a vital link with postgraduate training As such they need careful examination and control so that they may provide the necessary experience †

Postgraduate training after registration is as important for the general practitioner as for anyone else Part of it must clearly be as a trainee assistant, but it should also include *non resident appointments* in hospital departments—e g , psychiatric, ophthalmic, and dermatological The present tendency to give such appointments only to men who are going to specialise in these subjects is most unwise There should also be appointments, probably of the "rotating" type, especially contrived for those who wish to take up general practice, and for young practitioners who have discovered a weakness in their experience, or a special interest which requires a firmer basis It is unjustifiable to discredit future general practitioners by suggesting that they would be less willing than others to prepare themselves properly for their work This branch has for centuries attracted many of the finest men in medicine, and it will continue to do so

Reasons for Choice of Plan

I have three reasons for preferring to any other the plan I have described

Firstly it forms a continuous process which is in the beginning entirely educational and then becomes progressively more vocational

Secondly, it should surely be a guiding rule in any education that uniformity of the curriculum is avoided so far as possible not only individual schools but also individual students in a school, should be free to differ from each other This plan makes possible the easy absorption into clinical schools of students from the universities of Oxford and Cambridge, and it enables students in any university to diverge from the main stream at the completion of the first stage in order to take an honours degree in medical science The first stage means a considerable reduction in the content of anatomy and physiology as at present taught—although, of course students would meet these subjects and teachers in later stages I believe such a reduction is essential for many students, but a large number are capable of going further and it is right for them, and imperative for future advance in medicine, that they should be able to do so The present proportion of those who now take the B SC is too small

But though we must allow "divergence" of students, any arrangement by which they were separated into two streams on arrival at medical school would be utterly wrong Students should be free to diverge not only for an honours degree in the preclinical sciences, but in pathology, and (one would hope), some day in clinical science also

Thirdly, the plan pays due regard to the importance and the difficulty of acquiring a sound basis in clinical technique When the student is first introduced to this he should be as free as possible to concentrate upon the method of learning which it requires and should receive instruction from those expert in giving it

The alternative system—inclusion of clinical technique from the start, so that the student learns how to examine each part of the body while he is learning its normal structure and function—has been in operation in Western Reserve University for nearly four years I do not think it helps the student to acquire any better basis in clinical method and I think it may result in one not so good Because it is capable of enlivening the study of anatomy and physiology, it is often suggested as a necessary reform, but this seems to me an insufficient reason for an arrangement that may weaken the foundation in clinical medicine It is the less convincing because where anatomy and physiology are taught well and under good conditions—as at Western Reserve—they are not dull

I do not wish to disparage in any way the great service this university has done to medical education everywhere by its courageous and radical experiment—one that had to be made Moreover the change in curriculum is not the only, and not the most important experiment at Western Reserve There is also an experiment in interdepartmental teaching, which is I think successful There is a successful experiment in a tutorial system And above all, there is an experiment in the ability of a medical school to conceive, adopt and put into action an agreed educational plan This last has been an unqualified success, and the form of the curriculum which this school develops is of little importance compared with the immense stimulus its staff have received in its development The deficiencies of any curriculum can be remedied by the concerted efforts of an enlightened and interested teaching team, and Western Reserve has given us a lesson in medical education which we cannot afford to ignore

Educational Requirements

Any medical school in this country could take immediate steps to devise an educational plan, and it would then see what additional facilities it would need to put the plan into effect The curriculum which it might eventually adopt would be the product of the available facilities as much as of the plan itself

We can envisage some of the difficulties which would be encountered

The provision of proper accommodation would almost seem axiomatic, but it is surprising how hard it can be to get space at appropriate times for all the various learning and teaching methods I have described Clinical theatres, suitable outpatient consulting rooms, rooms for tutorial and group discussions, facilities for laboratory investigation by both staff and students—all these are essential to education but they are seldom easily found Since the patient is no longer indifferent to and uninterested in remarks at the bedside, there must also be rooms for ward teaching away from the patient

A more obvious need is for clinicians to be able to give more time to teaching I have mentioned the American system of geographically full time consultants and the extraordinary difficulties the National Health Service has placed in the way of our having a similar system But no adequate plan can be fulfilled unless this problem is tackled

Finally under the heading of facilities for teaching we come to the question of clinical material I have referred to the distortion and fragmentation of the student's clinical experience, but specialisation in teaching hospitals is not the only problem There

† Many of these posts already differ greatly for various reasons from pre-war house appointments, and it is unfortunate that the newly qualified are often given advice on their postgraduate training which fails to take this into account

In England Now

A Running Commentary by Peripatetic Correspondents

For many years it has been my lot to [illegible] other people's children—but last week found me at the other end of the [illegible]. I arrived at [illegible] a.m. at a welfare centre in North [illegible] with my eight-month-old son and sat in a [illegible] with a [illegible] other mothers and their children waiting with [illegible] appointments for our first [illegible]. It was a [illegible] Christmas [illegible] established that the [illegible] present [illegible] November [illegible] were [illegible] a [illegible] if I were [illegible] that she [illegible]. At [illegible] I [illegible] but [illegible] the [illegible] of the other children and seeing the [illegible] I [illegible] my arms. I explained that the [illegible] to which I am [illegible] by [illegible] to be in the [illegible] I [illegible] even my son [illegible] me, and the [illegible] that some of our [illegible] the [illegible] my [illegible].

[illegible] was our turn to enter this [illegible] left [illegible]. The [illegible] was [illegible] to take [illegible] exercise for a week—[illegible]. The first signs of [illegible] and [illegible] eyes filled with tears. "No [illegible]" asked this [illegible]. The [illegible] confidential [illegible]: "[illegible] is something I do not understand—but [illegible] a very [illegible] I think."

* * *

"Cambridge should be a man's university" was the cry of graduates and undergraduates of my generation back in the '20s. Women had been [illegible] that had gained equality in all the other British universities and they should be content. Members of Girton and Newnham attended lectures and were like ordinary undergraduates until they came to the end, when they were allowed to take their degrees by [illegible] and [illegible] because [illegible] did not have to pay graduation fees. The chief [illegible] was that they [illegible] not [illegible] posts.

The crisis came, so we thought, in 1921 when a [illegible] of the senate recommended that women should be admitted to degrees and given representation on the council of the senate. The [illegible] phrase "[illegible]" was an understatement. Clergymen who rarely left their parishes were [illegible] to vote and doctors who were supposed to be [illegible] the [illegible] were travelling in from [illegible]. Still was the [illegible] and sometimes not even on that. The great day arrived and [illegible] graduates voted. The figures were given from the Senate House: [illegible]. The news [illegible] that the non-placets had defeated the grace and kept the women in their place, rushed to Newnham. The gates were closed against us. The trucks were quickly collected from porters and used as battering rams against the [illegible] gates. (We [illegible] know the beauty of the [illegible] then, and it was a shock to all of us to find that these gates were of great artistic value.) The authorities had [illegible] the police who arrived expeditiously and the [illegible] quickly [illegible] "The police have drawn their truncheons." It is [illegible] years ago, but I can still remember [illegible] my [illegible] and [illegible] off like a dog with his tail between his legs. [illegible] was [illegible] but true [illegible] came later and as [illegible] slowly led to conversion.

[illegible] an educated wife and two daughters as worthy of our university education as my son have all played a part. So has women graduates' ready acceptance of the responsibilities of educated citizens.

In 194[illegible] women were admitted to full membership of Cambridge University, and equality and [illegible] were achieved. [illegible] except their ineligibility for the office of proctor and [illegible]. All [illegible] will be well if [illegible] Newnham [illegible] take all the [illegible] who want to have a Cambridge University [illegible] but [illegible] and [illegible] this by [illegible] to found a third women's college. New Hall [illegible] seat of learning like its [illegible] and [illegible] hope is that [illegible] Cambridge will help to [illegible] Cambridge provides the best [illegible] in the world.

* * *

[illegible] an exhibition of historical documents at [illegible] the other day, I [illegible] a letter from [illegible] the [illegible] Nov. [illegible] to March [illegible] [illegible]. The [illegible] signatures of [illegible] gentlemen of the [illegible] the Church [illegible] at their [illegible] always [illegible] been [illegible].

* * *

[illegible] I [illegible] a [illegible] Christmas. It was only a [illegible] by a [illegible] particularly [illegible] specimen of English [illegible] that saved Sir Francis from a [illegible] the [illegible]. The [illegible] of the Lady [illegible] and so the [illegible] with a [illegible] set of [illegible]. With the coming of spring our [illegible] and [illegible] the garden, and [illegible] Sir Francis [illegible] in his [illegible]. [illegible] up with [illegible]. We [illegible] until [illegible] and [illegible] began [illegible] heavily [illegible] a [illegible] in the [illegible]. I [illegible] him for his [illegible] between his [illegible] a [illegible] and [illegible] a [illegible]. We took advantage of this [illegible] to investigate the [illegible]. [illegible] is a natural [illegible] of the church. She [illegible] "[illegible] seen Sir Francis [illegible] a proper gentleman." But I have [illegible] of the [illegible] of the [illegible] that I am [illegible] this year.

* * *

I [illegible] have a perfect reply to philistinism. Passing from the [illegible] with the French [illegible] at the Tate to the [illegible] exhibition of German painting, we stopped to examine one of the striking large canvases. It was a [illegible] of [illegible] and irregular shaped [illegible] of [illegible] and no [illegible]. My wife [illegible] about if [illegible] Peter [illegible] something like it. This was [illegible] by a [illegible] who [illegible] with perfect [illegible]: "May I respectfully suggest, Madam, that he tries."

* * *

May I [illegible] upon the [illegible] of the [illegible] and, with respect for the [illegible] of the [illegible] to the physician, suggest that we rename the [illegible] the [illegible] of [illegible]?

function of doctors—as it must, not least because medical care is now part of the economic life of the nation

The third step in the reform of medical education is, therefore, to establish a means whereby it can itself be studied   Research is necessary in three things—in learning, in teaching, and in the pattern of medical practice   On the first two depends the future improvement of medical education   On the last depends the nature of the work students are eventually going to do   All three are the vital concern of the university medical schools   Their investigation requires a focus from which stimulation as well as correlation can come   A body capable of providing this focus must be found in the form of either a national council or an institute of medical education   Here is a supreme opportunity for collaboration between the Royal Colleges and the medical faculties of the universities—a collaboration at the educational level which would inevitably form a basis for wider cooperation in all fields of medical practice

EFFECT OF OXYGEN ON EXERCISE ABILITY IN CHRONIC RESPIRATORY INSUFFICIENCY

USE OF PORTABLE APPARATUS

PNEUMOCONIOSIS RESEARCH UNIT OF THE MEDICAL RESEARCH COUNCIL, LLANDOUGH HOSPITAL, PENARTH, GLAM

THE effective control of acute respiratory infections in patients with chronic pulmonary disease has probably increased the number of such patients who progress to breathlessness on the slightest exertion   When such patients breathe oxygen, their arterial oxygen saturation is restored to normal (Comroe and Dripps 1950), their uptake of oxygen during exercise is increased (Valentin and Venrath 1952), the ventilation for standard exercise is reduced (Zorn 1940, Altschule 1954), and sometimes their ability to exercise is greatly improved   Therefore it seemed possible that portable oxygen equipment might have a use   Suitable apparatus has become available as a result of the development of equipment for supplying airmen and mountaineers with oxygen (Cotes 1954)   We describe here an attempt to assess its usefulness in the symptomatic treatment of men with chronic respiratory failure

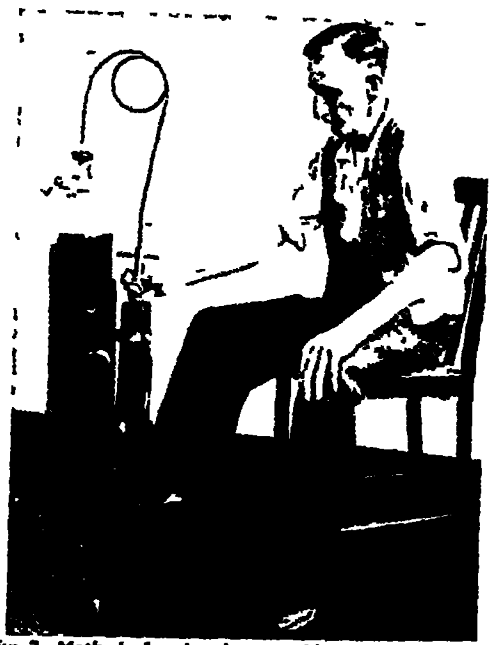

Fig 2—Method of recharging portable oxygen apparatus

Apparatus

One or more small light weight steel cylinders containing 50–120 litres of oxygen at a pressure of 120 atmospheres are connected to a pressure gauge, a reducing valve, and a flow selector   The complete apparatus for 120 litres of oxygen weighs $2^1/_2$–$3^1/_2$ lb   More oxygen can be stored by using multiple cylinders but the weight is not increased in proportion, since the cylinders share a common pressure regulator

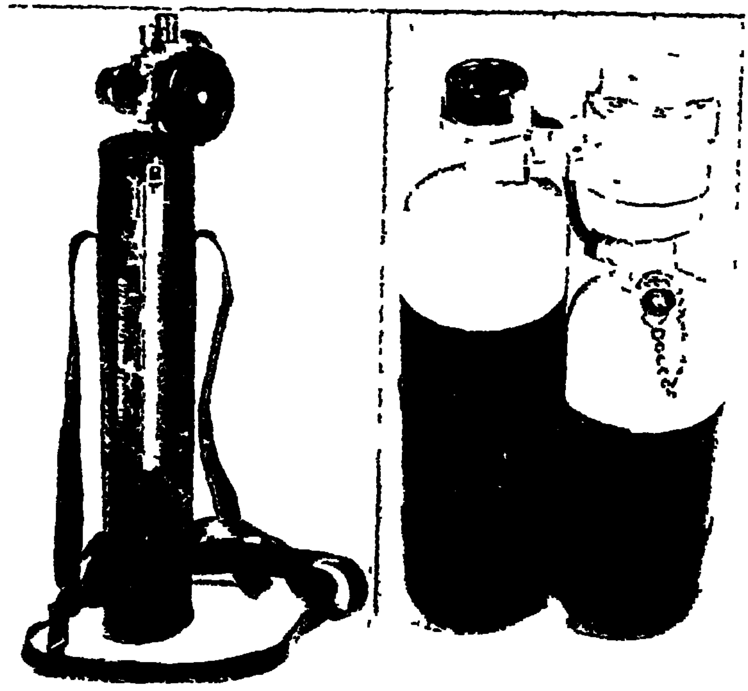

Fig 1—Portable oxygen apparatus

Two types of apparatus are illustrated (fig 1)   In one the oxygen flow is controlled by an on off cock, and two flow settings are available   This apparatus can be carried comfortably on the shoulder   In the other, the squat two cylinder type which goes into a pocket, the on off cock and flow selector are combined into a single switch, which can be turned from "off" to any one of five preselected flows

Charging has been done from a standard cylinder with a simple jig which can be operated by the patient (fig 2)   This is not entirely satisfactory, because the pressure in the charging cylinder will remain high enough to transfer a useful quantity of oxygen to the smaller cylinder for only a limited number of refills (fig 3), however since those who benefit from the portable apparatus often use standard cylinders at home the half charged ones can be used for this purpose   Sets are being developed with detachable cylinders which could be charged at a central depot and supplied to dispensaries by the dozen in manageable packages for distribution   Domiciliary recharging of portable sets would then be avoided and the difficulty of distributing unwieldy oxygen cylinders to private homes overcome in many cases

(2) Those in which there is considerable delay in removing clothing which has been saturated in boiling liquid Most of these scalds occur in the region of the axilla and upper arm, or in the groin—both sites where hot liquid tends to "pool" In our survey last year we found 15 cases, all in children, in which there was definite delay in removing clothing after a scalding injury All of these children required skin grafting, 5 needing two, and 2 needing three, grafting operations In all these children, woollen garments, such as cardigans and knickers, were worn at the time of the accident, and it is our impression that these knitted garments hold the heat much longer than other materials

The importance of early removal of clothing from scalded patients is not widely appreciated, and the Ministry of Health advice note 5/54 states that "in the event of a burn or scald no attempt should be made to pull the clothes off the skin " This is no doubt put forward in order to prevent further shock by rough handling of the patient, but certainly in the case of scalds retention of sodden hot clothing may cause unnecessarily deep destruction of the skin

RESPIRATORY INVOLVEMENT IN POLIOMYELITIS

SIR,—We welcome the discussion on the management of bulbo respiratory complications in poliomyelitis which has taken place in your journal, and particularly the consideration given to the correct place of tracheotomy It is timely that experience in this field should be pooled at the beginning of the poliomyelitis season as it is no longer necessary to be guided by the data collected during the Copenhagen epidemic of 1953, which was responsible for the great increase in the method in the U K

Dr Scott and Dr Knox (April 21), in an interesting discussion on their experience in transporting twelve cases of bulbo respiratory paralysis last year, suggest that it might be better to perform tracheotomy before the journey, so that the trachea can be protected by the cuffed tube from aspiration from the pharynx, and positive pressure respiration can be given by the same tube if necessary Dr Crampton Smith and Dr Spalding (May 5) reply suggesting that for the period of transport it is better to use an *oral* cuffed tube passed under local anæsthesia, and to perform the tracheotomy once the patient is "under good conditions on arrival at the final hospital" We should like to support the first part of the latter recommendation but to add that by the time the patient has reached "good conditions" one of the two major hurdles—namely, transport—is already passed, and that instead of performing a tracheotomy on arrival the resources of the hospital should be directed to avoiding this intervention if at all possible Thus, while the oral tube is in place the patient can be prepared for its removal, and for the use of negative pressure respiration by (*a*) emptying the stomach and lower bowel (vomiting, associated with restlessness, is probably the other major hurdle), (*b*) effective sedation, (*c*) transfer to a cabinet respirator to be maintained in a steep head down tilt after removal of the tube, and (*d*) the establishment of effective replacement therapy If necessary the lungs can be cleared by direct vision with a bronchoscope, and of course effective suction must be constantly available to keep the pharynx clear

It has been our unfortunate lot for the past eighteen months to observe what a tragic complication a tracheotomy can be in a condition such as poliomyelitis, which may leave behind severe residual respiratory paralysis Such patients have virtually no cough, and chronic pulmonary infection appears to be an inevitable consequence of the stoma This infection reduces both the effective ventilation obtained by the residual respiratory power, and also the area of healthy lung tissue available for respiratory exchange Consequently the recovery of spontaneous respiration is severely handicapped, and, so long as the stoma and therefore the chronic infection persist, weaning from aid may be impossible Yet closure of the stoma is fraught with danger because of the chronic infection in the absence of a useful vital capacity and effective cough The patient is, in fact, trapped in a vicious circle, and the period of rehabilitation is either grossly prolonged by months or even years, or closure, and consequently rehabilitation, may have to be abandoned altogether, with the result that the patient may be condemned to permanent stay in hospital for the rest of his days There are, in fact, a number of cases with severe respiratory paralysis now living in relative happiness at home for whom such a solution would have been impossible had a tracheotomy been performed in the acute stage, and some of these cases would have been in real danger of this complication had they fallen into less conservative hands at that time

Obviously, the decision to perform a tracheotomy in a particular case must rest with the man on the spot Our object in writing is simply to pass on to him the product of our own experience in managing such cases of severe respiratory paralysis complicated by stomata in the recovery period, so that he may take our viewpoint into consideration when making his decision In practice, we believe that the suggestion made by Dr Crampton Smith and Dr Spalding—that the danger period of transport should be tided over by means of an oral endotracheal tube—should be extended to tide over the rest of the acute episode, and that both "prophylactic" tracheotomy and tracheotomy for the sake of administering artificial respiration by positive pressure should be almost limited to patients who fall ill beyond the reach of full hospital facilities and thus have mainly a "geographical" indication

The time for which an oral tube can be left in situ is still, we understand, sub judice Figures varying from eight to forty eight hours or more have been cited to us by different authorities Certainly in one case a duration of forty eight hours was risked with impunity The danger period in poliomyelitis is fortunately often relatively short, and for this reason one should be the more reluctant to superimpose a complication which may have such lasting serious consequences if there is any hope that it can be avoided

Nuffield Orthopædic Centre,
Oxford

M AGERHOLM

PARAPLEGIA FOLLOWING SPINAL ANÆSTHESIA

SIR,—Dr Payne and Dr Bergentz (May 12) do well to draw attention once more to the well established clinical fact that paraplegia ensuing upon spinal anæsthesia may appear only several days after this procedure, and may then progress slowly for a further period of days or even weeks

Their case exemplifies also another established fact—that the immersion of ampoules of spinal anæsthetic in toxic solutions for purposes of sterilisation is by no means a constant factor in recorded cases of neurological complications after spinal anæsthesia

The only factor common to all these cases is the use of a spinal anæsthetic

The relevant literature makes it clear that the patient has often severed his ephemeral connection with the anæsthetist before his neurological syndromes—particularly the less severe ones—develop Therefore what the anæsthetist does not hear about may nevertheless have happened

Sir Robert Macintosh returns from Africa, not "with something new," but with the old story that what he has not heard about has not happened In his letter last week he cites again his single experience of the ampoule contaminated through invisible cracks by the coloured fluid in chest infection or of right heart-failure The remaining 12 were admitted for the series, of whom 9 were found to benefit by active medical treatment before beginning graded exercise on the treadmill

In 22 of the 29 patients the walking distance was at least doubled when they were breathing oxygen, compared with air (table I) In most cases this result was obtained with a mouthpiece or mask of the oxygen-reservoir type, but 2 men (cases 15 and 28) got little benefit until a nasal catheter (*flow 6–8 litres a minute*) was substituted Of the remaining 7 patients exercise was limited in 2 (cases 2 and 23) by giddiness and in 1 (case 18) by pain in the chest 2 (cases 6 and 19) showed only a small improvement on oxygen (34% and 22% respectively), and 2 (cases 3 and 17) showed no change

Minimal Effective Oxygen Flows and Influence of Design of Oxygen Mask

In 6 patients an attempt was made to determine the minimal effective quantity of oxygen by varying the oxygen content of the inspired gas and the method of its administration (table II) Tests were so arranged as to allow for the effect of order of tests on exercise ability and for day-to-day variations

The first patient to be studied in this way (case 21) did 6 walks on each of six days, breathing 20%, 25%, 30%, 50%, and 100% oxygen through a mouthpiece and using a portable oxygen set with flows of 2, 3, and 4 litres a minute delivered to an oronasal mask The results (fig 4) suggest that this patient paused for breath when his exercise ventilation exceeded 14 litres a minute, and that sensations arising as a result of changes in arterial oxygen saturation were not themselves directly responsible for his stopping From the findings it appeared improbable that 25% oxygen in the inspired gas mixture would be sufficient for patients in this condition, and this mixture was not considered further

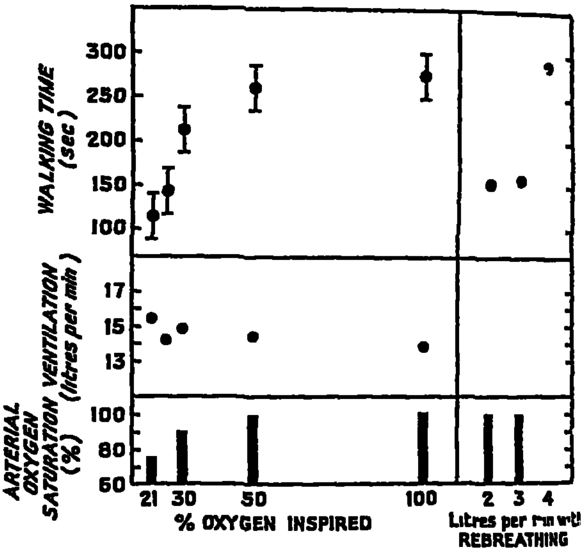

Fig 4—Effect of oxygen on walking time (case 21)

When the lines drawn about a pair of points do not overlap the difference between the points can be said to be significant

The relative efficacy of the seven remaining combinations was determined in triplicate in 2 further patients (cases 4 and 7) The results (fig 5) are in agreement with

TABLE II—EFFECT OF OXYGEN ON WALKING TIME, EXERCISE VENTILATION, AND ARTERIAL OXYGEN SATURATION

* Applies only to O₂/N₂ mixtures

or raised plasma-sodium values might excrete abnormally low amounts of aldosterone In that case slightly raised excretion of aldosterone under these electrolyte conditions may be diagnostic for the presence of tumour Thus the values in the case of Chalmers et al as measured some time before the operation could be explained by a combination of aldosterone secretion by a tumour relatively autonomous to electrolyte control together with that from normal adrenal tissue which is depressed by the prevailing state of potassium depletion This depletion would have given rise to a low excretion of aldosterone for a subject with a totally normal gland This could also explain the great decrease in aldosterone excretion after removal of the tumour down to values found in totally adrenalectomised patients whereas the cortisol values are only halved and presumably one gland remains intact In our opinion this speculation which can be investigated experimentally, would appear to be the most fruitful approach to the problem at the present time

It should be emphasised that this suggested reduction in aldosterone excretion in potassium-losing nephritis without tumour would not be due to nephropathy caused by hypokalæmia as reported in your annotation, but to a selective effect of the mineral environment on the adrenal secretion of aldosterone

COMPOSITION OF FLOUR

Sir.—According to the Panel on Composition and Nutritive Value of Flour, whose report you summarised last week the millers and bakers claim " that if people can obtain only bread made from 80%-extraction flour they may eat less bread and more of other manufactured foods which may not be so nourishing " It does not appear to have occurred to the industry that it would be better for the public health to engage in proper milling and baking that is, milling to leave in all the germ and resist its subsequent sterilisation by whatever process has superseded agene, while in baking such things as anti-staling agents and all chemicals should be left out so that bread is only flour and yeast Then English bread would again have a pleasant taste and substance and a crisp crust, instead of being the worst bread gastronomically in Europe The consumption of bread would improve as it gave pleasure to the public, dividends would improve and health would improve

London W 1 Franklin Bicknell

FATS AND DISEASE

Sir,—In spite of forty-three years of single-minded experimentation the dietary theory of atherogenesis has remained pure speculation All that has been shown is that the levels of certain serum-lipid fractions are raised in many cases of atheromatosis, it is a far cry from this to a causal relationship These increased levels may mean no more than that atherosclerotic plaques contain lipids—hardly a very striking contribution to knowledge

Even if it could be shown that these abnormal blood levels are indeed an important causal factor in human atherogenesis, it would still remain to be proved that they were due to feeding habits. Numerous bodily reactions affect the blood-lipid balance, each one of which might be inculpated with equal, and most with better, justification Myocardial infarction itself is one of these many causes of lipæmia [1]—a fact which illustrates strikingly the weakness of the dietary theory

The war-time decline in the incidence of coronary disease is cited in support of this theory as if a low fat content were the only characteristic of a war-time diet With much better justification one might speculate about the hypotensive effect of a low-calorie and low-protein diet on the population and on its obese contingent in particular These effects are well attested as is the atherogenic effect of hypertension

Do general practitioners really eat twice as many eggs as their consultant colleagues ?[2] Do bus conductors refuse to share sunflower cakes with their drivers ?[3] In spite of widespread publicity nothing has yet come to light to suggest that diet plays an important part in any but a small fraction of the people who come to grief as the result of atherosclerosis

Edinburgh Erich Geiringer.

TREATMENT OF SUPERFICIAL SEPSIS

Sir.—Dr Bauwens and his colleagues are to be congratulated on their valuable and interesting paper last week The general adoption of the methods they describe however, would lay an additional burden on already overworked departments of physiotherapy Any evidence concerning the efficacy of physical methods as a routine measure in the treatment of minor sepsis should, therefore be examined with care

It is for this reason that I venture to suggest that their control and treated groups are not strictly comparable. The wounds in the treated groups were dressed with tulle gras or tulle gras and aureomycin powder while in the control group 1/1000 proflavine was applied The use of a different dressing, whatever its nature for the control group would alone appear to detract from the validity of their findings. In addition there is evidence that proflavine in dilutions as high as 1/120,000 exerts an inhibitory effect on the growth of fibroblasts and macrophages [4] It is conceivable, therefore, that the use of proflavine, particularly its repeated use may have delayed the healing-time in the control group

While the methods advocated are of undoubted value in cases of minor sepsis which fail to respond to accepted measures it is doubtful on available evidence whether they should be used in every case

St George's Hospital
London, S W 1 Michael E. Fearnley.

TREATMENT OF TETANUS

Sir —Professor Lassen and his colleagues (April 28) describe two cases of severe tetanus in which protracted administration of 50% nitrous oxide and 50% oxygen led to fatal aplastic anæmia, caused, they suggest by the nitrous oxide

Is it not possible that the oxygen, rather than the nitrous oxide, was the cause ? It is known that anoxia is the usual stimulus to red-cell formation and living at high altitudes leads to polycythæmia in compensation for the reduced partial pressure of oxygen Conversely, with high pressures of oxygen the formation of red cells is depressed [5] With administration of 50% nitrous oxide and 50% oxygen the partial pressure in the alveoli is raised some three and a half times, and it is possible that over a period of days this partial pressure of oxygen removes the natural stimulus of anoxia to red-cell formation The agranulocytosis in the cases described by Professor Lassen and his colleagues would not rule out this thesis, if in fact the hæmocytoblast is the common precursor of both the red cell and the granulocyte.

A further trial would seem to be indicated using 20% oxygen with 80% nitrous oxide or, better still (since only one factor would be varied), 20% oxygen, 30% nitrogen, and 50% nitrous oxide

tution of cartons of small cylinders of the type used in portable equipment (weight 25 lb per 48 c.ft capacity) for the 48 c.ft cylinders (weight 35–45 lb) in present use. This change would also greatly ease the burden, which in our experience usually falls on the dispenser, of transporting oxygen to the patient's home and of carrying it upstairs to the bedroom.

To make the best use of portable oxygen and any domiciliary supply, an accurate leak-free pre-set flow selector is essential (fig. 7). The regulator developed for the portable equipment could be used on the standard cylinders and would save much oxygen. For maximal economy a well-fitting mask of the oxygen-reservoir type, with a check valve to prevent rebreathing, should also be used.

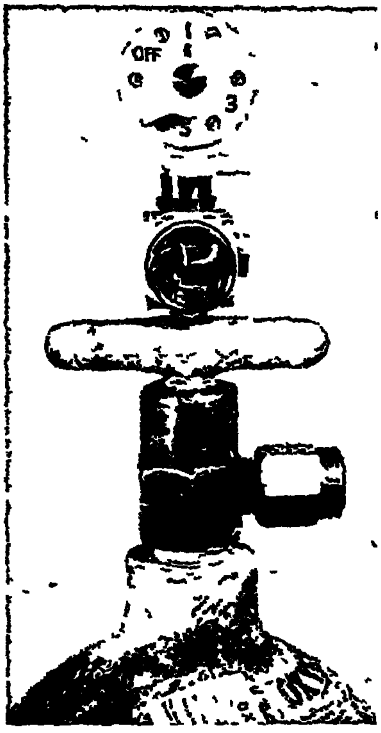

Fig. 7—Oxygen regulator and flow selector adapted to fit standard oxygen cylinder.

Discussion

Our results show that, in a fair proportion of patients with chronic respiratory infection and severe respiratory disability, a further useful increase of exercise ability above that produced by intensive chemotherapy can be produced by breathing 30% oxygen.

It is our impression that such patients gain in exercise ability by breathing oxygen only if they are prepared to exercise to the point of some visible respiratory distress while breathing air. Some patients do so constantly, and others may wish to do so after treatment and rehabilitation, but some patients apparently cannot exert themselves so far. This variation is a manifestation of the patients' attitude to their disease and need not represent any difference in the underlying pathology, though this cannot be excluded. It is likely to be the major factor affecting the success or failure of portable-oxygen therapy in the individual case.

The increased exercise ability when the patient is breathing oxygen is probably due to a reduction towards the normal levels of the ventilatory requirements for exercise as a result of the relief of anoxia. The reduction of ventilation causes a rise of the arterial carbon dioxide tension (Haldane and Priestley 1935), which could lead to loss of consciousness (Donald and Davidson 1954). This complication has not been observed, and the risk can be reduced by restricting activity to essential tasks and by using minimal effective oxygen flows. Addiction to oxygen is a more serious risk, but it is one to which many of these patients are already exposed when using domiciliary oxygen and is probably not increased by making the equipment more portable; but it is a reason for limiting the use of oxygen to those who get real benefit from it.

Portable oxygen should be regarded as an integral part of domiciliary oxygen therapy. A review of existing equipment and the cost of supplies is needed. This might be expected to lead to much improved equipment and to the more effective use of oxygen, with an ultimate saving of cost to the National Health Service. Demand is likely to increase because an ageing population is likely to contain more people with chronic respiratory failure.

Summary

Breathing oxygen usefully increased exercise ability in most of 29 patients selected as having severe chronic respiratory insufficiency. The effect was measured by the increased time they could walk on a treadmill.

From detailed studies of 6 patients it is concluded that 30% oxygen in the inspired gas is not greatly inferior to 50% and 100% oxygen in increasing exercise ability. An effect similar to 30% can be obtained from an oxygen flow of 4 litres a minute delivered to a well fitting oxygen mask, with an oxygen reservoir bag protected by a check valve to prevent rebreathing. Exercise ability is significantly impaired by the omission of this valve.

Portable oxygen equipment is described which has been used successfully by 4 patients in their homes.

The need for improved portable and domiciliary oxygen equipment is emphasised.

It is a pleasure to acknowledge our indebtedness to Mr F. Purse, of the Prescription Pricing Bureau, Wales, for information on the supply of domiciliary oxygen equipment to dispensaries; to our colleagues, in particular Mr P. D. Oldham, for help with the design of the experiments and with the statistical analysis of the data; to Dr J. A. L. Gorringe, Dr C. B. McKerrow, and Dr J. B. West for the clinical care of our patients; and to Mr A. J. Merrick, Mr F. Meade, and Mr R. T. Harris for technical and photographic assistance. Messrs Walter Kidde & Co. Ltd., Northolt, Middlesex, and Messrs Normalair Ltd., Yeovil, Somerset, provided the portable oxygen equipment.

BRONCHIAL CARCINOMA

EFFECT OF RADIOTHERAPY ON SURVIVAL

J. R. Bignall
M.A., M.D. Camb., M.R.C.P.
SENIOR LECTURER, INSTITUTE OF DISEASES OF THE CHEST, BROMPTON HOSPITAL; RESEARCH ASSISTANT, INSTITUTE OF CANCER RESEARCH, ROYAL MARSDEN HOSPITAL, LONDON

There is no indubitable evidence that radiotherapy prolongs the life of patients with lung cancer.

No clinical trial has been recorded in which patients were allocated at random to treated and untreated groups; and, since it is generally agreed that the treatment can improve or relieve certain distressing symptoms, it is doubtful whether such a trial would be justified. But with a large number of case records and a knowledge of factors influencing survival it might be possible to construct groups sufficiently comparable to demonstrate differences in survival, if they are large enough to be practically important.

In this report the survival of 207 patients treated by radiotherapy is compared with that of 248 who were not so treated.

As a G P obstetrician in the London area I can only hope that the county authorities have little or no part to play in the new organisation At present the antenatal and postnatal clinics in my district are staffed by L C C medical officers, and their sole duties in the maternity services are those of antenatal and postnatal care, they are completely divorced from all other aspects of midwifery There appears to be no liaison between the clinic doctor and the G P obstetrician I cannot recall receiving any communication from the clinic doctors during the last ten years, although I undertake the care of many midwifery cases

While I am certain that these medical officers give care of the highest order, I am equally certain that it is not right for this vital part of the service to be so cut off from the actual labour and puerperium, and conversely it is equally wrong that the G P obstetrician should have to treat emergencies in the mother's home at all hours of the day and night despite the fact that he is not considered to exist during the antenatal period

It seems to me that the district midwives, the G P obstetricians, and the obstetric hospitals in the area should be responsible between them for all midwifery in that area, both hospital and domiciliary They could form a team in the real sense of the word, and in this team there would be no place for the splendid isolation of the local health authority

I realise that the local health authorities employ the district midwives and health visitors and others, but they, too, could come under the unified control and be part of the team

London S W 11 **IAN SAMUEL**

RHESUS (D) FACTOR IN SARCOIDOSIS

SIR,—Dr Cudkowicz has reported (April 21) that of 32 cases of suspected sarcoidosis 21 (66%) had rhesus (D) negative blood He suggested that a larger series should be analysed I have investigated this point in 80 cases of clinical sarcoidosis at King's College Hospital The results are as follows

Rh (D) factor		*ABO group*			
Pos	*Neg*	*A*	*B*	*AB*	*O*
68 (85%)	12 (15%)	36 (45%)	6 (7·5%)	4 (5%)	34 (42·5%)

All but 2 of the 80 cases had pulmonary and/or hilar-node involvement

Thus the prevalence of Rh (D) negative blood in our 80 patients was 15% This figure is in accordance with the prevalence in the general population and is at variance with that found by Dr Cudkowicz

In my opinion Rh (D) negative blood has the same prevalence in patients with sarcoidosis as in the general population

ANÆSTHESIA IN OBSTETRICS

SIR,—Dr Coleman and Dr Day (May 19) are to be commended for drawing our attention to the complications due to aspiration of stomach contents during obstetric anæsthesia They have obviously anæsthetised their patients with great skill and care, and their results are due to this rather than to the technique they adopt which courts the very dangers they seek to avoid

By their method Dr Coleman and Dr Day steer clear of the Scylla of vomiting, but in so doing head straight for the whirling Charybdis of regurgitation For, if the stomach be full, the omission of the passage of an œsophageal tube before giving a paralysing dose of relaxant, and inflating the lungs, however gently, is flirting with disaster This danger of regurgitation overcome, only a fickle laryngoscope bulb and pious hopes of a normal epiglottis stand between easy intubation and those few moments of anoxia that may mean all the difference between life and death to the fœtus

We all pass through the phase of using large doses of relaxants and universal intubation but where two lives are at stake, surely would it not be better to ensure that one person at least is breathing spontaneously? To say that the anæsthetic problem involved is similar to that in a case of intestinal obstruction is incorrect, for full abdominal relaxation is needed for the latter, whereas even for a cæsarean section only very moderate relaxation is sufficient We must not be so blinded by our magic drugs and chromium-plated gadgets that we fail to recognise the essential requirements of our partners the surgeons

I have lately described a very simple and safe general-anæsthetic technique that I have found most satisfactory for all obstetric cases[1] Alternatively, as far as forceps deliveries are concerned there is much to recommend caudal or (dare I mention it?) low spinal anæsthesia

Gravesend and North Kent Hospital **PAUL AZZOPARDI**

SIR,—Dr Coleman and Dr Day have done a great service in again drawing attention to the dangers of vomiting during the administration of anæsthesia for obstetric operations The method they advocate is doubtless safe in their capable hands, but I feel that attention should be drawn to the feeling that many anæsthetists have about the danger of giving any relaxant and especially succinylcholine in a case where the stomach may be full

They say "attempting to pass a Ryle's or œsophageal tube on a woman in labour increases her fear and distress" This may be so, but the remark would apply equally to a case of intestinal obstruction or ileus Would they agree to omitting the passage of such a tube in these cases? I feel that any woman in labour must be treated as a potential case of ileus, and a full stomach anticipated even if no food has been taken for many hours Surely the passage of a large bore Ryle's tube should be a routine in all such cases?

It is possible to intubate a patient harmlessly without the use of a relaxant It was done before relaxants were introduced into anæsthetic practice, and I believe should be done in any case where vomiting is anticipated

Worthing **F R GUSTERSON**

SIR,—Great attention is being paid to this subject at present, and endotracheal intubation with a cuffed tube is often advocated as a protection against inhalation of gastric contents The relative safety of different methods of producing suitable conditions for endotracheal intubation are still sub judice, and even experienced anæsthetists sometimes cannot perform the intubation itself as rapidly as they would like Moreover techniques safe in hospital practice may be dangerous outside hospital

If it is considered that general anæsthesia with no artificial airway, except perhaps a nasopharyngeal tube, is hazardous the cuffed gastric tube described by Fisher[2] might be of value This is a small stomach-tube with an inflatable balloon situated distally After this end has been passed into the stomach the balloon is inflated and drawn firmly against the cardiac orifice, thus preventing reflux of stomach contents Anæsthesia is then induced

This technique is simple Patients who will not tolerate attempts to pass the tube will probably empty their own stomachs by vomiting during this time It is unpleasant for the patient, but some anæsthetic techniques that do not proceed without a hitch are unpleasant for the fœtus as well as the mother

It would be interesting to know what experiences practitioners have had of this method

TABLE II—DURATION OF SURVIVAL AFTER FIRST ATTENDING THE HOSPITALS

—	Total no.	Proportion (%) surviving after (yr.)		Proportion (%) surviving (mos.)				
		1	2	0–5	6–11	12–17	18–23	24–
No mediastinal metastases								
1000–3900r	49	30	6	37	33	12	12	6
Untreated	148	20	5	54	25	11	4	5
4000r or more	54	35	15	22	43	15	5	15
Untreated	126	24	6	47	29	13	5	6
Mediastinal metastases								
1000–3900r	63	19	3	46	35	11	5	3
Untreated	100	25	8	45	30	12	5	8
4000r or more	39	38	13	20	41	15	10	13
Untreated	89	28	9	38	34	14	5	9

groups probably contained more patients in an advanced stage of cancer who, although having no demonstrable distant metastases, were yet considered too ill to withstand radiotherapy. Their number is unknown. But there are known to be differences between the groups in the proportions considered to be in too poor a condition to withstand pulmonary resection. For instance, in those without evidence of mediastinal metastases the proportions were 27% in the untreated and 11% in the treated patients. It seems fair, however, to conclude that the groups are not so grossly biased that a large difference in survival could not reasonably be attributed to treatment rather than to selection for treatment.

Survival

The experience of each radiotherapy group was compared with that of its corresponding untreated group. The duration of life after first attending hospital was preferred to the total duration of illness. The interval between attendance and death can be accurately recorded, but, since the length of illness before diagnosis is almost always approximate, the total duration of illness is inaccurate. Furthermore, the duration from first attending hospital is a more clinically useful expression of the experience of the patients. But the comparison is only valid if there are no large differences between groups in the estimated duration of illness before attendance. The differences are in fact small. Moreover, the effect of the previous duration of illness has been eliminated as far as possible by comparing, in addition, the experience of patients with histories of similar duration.

One-year and Two-year Survival-rates

In the group treated with less than 4000r the differences in the proportions surviving two years from first attendance were insignificant (table II). Among those without metastases 30% of the treated lived more than a year, compared with 20% of the untreated. The difference of 10% with a standard error (S.E.) of 7% is small. So also is the difference of 6% between the treated and untreated patients with metastases. The differences at one and two years are only slightly greater in the groups treated with 4000r or more. In those without metastases 35% of the treated and 24% of the untreated lived for a year or more—a difference of 11% (S.E. 8%). There was still a small difference of 9% (S.E. 8%) in those surviving two years. In those with metastases the differences are of the same order—10% (S.E. 9%) after one year and 4% after two years.

Pattern of Survival

The pattern of survival judged by the proportions living for successive six-month periods, was not greatly different in the treated and untreated patients (table II). In the untreated patients the largest proportion of deaths took place in the first six months, and the pattern of survival of those treated by less than 4000r is similar. In the group with mediastinal metastases the patterns are, *in fact, almost identical*. But fewer of those without metastases died within six months of first attendance—37% compared with 54%—a difference of 17% (S.E. 8%).

The differences in the group treated with 4000r or more are larger, and the biggest number of deaths among treated patients took place in the period between six and eleven months after first attendance. The differences in the proportions dying within six months were 25% (S.E. 7%) in those without metastases and 18% (S.E. 8%) in those with them.

The probabilities that the observed differences in the patterns of survival were due to random-sampling variations are more than 1 in 20, except in the case of patients without metastases treated with 4000r or more, where the probability is less than 1 in 100.

Previous Duration of Symptoms

Survival after first attending hospital is affected by the duration of previous illness.

Groups of treated and untreated patients with approximately similar durations of symptoms were therefore compared. 35 of the 54 patients without metastases who received 4000r or more had had symptoms for less than six months; 27 (77%) lived six months and 11 (31%) a year, compared with 51% and 21% of the corresponding untreated group. In those with symptoms for more than six months there were similar differences: 79% of the treated living six months and 42% a year compared with 56% and 28% of the untreated. Further subdivision according to length of symptoms produces groups that are too small for valid comparison, but the trend throughout is the same: whatever the length of symptoms the treated patients lived a little longer than the untreated. Thus 16 had been ill for three to five months; 13 survived six months and 6 a year. In the corresponding untreated group of 31 only 13 lived for six months and 4 for a year. In both those with metastases and those without, the differences between treated and untreated patients were smallest in the groups with the shortest previous illness. Indeed, in the case of patients with mediastinal metastases treated with small doses the corresponding untreated group with symptoms for less than three months fared a little better than the treated group; 55% of the 36 untreated survived six months and 22% a year, compared with 18% and 17% of the 29 treated.

Discussion

There are several reports of comparisons between the course of bronchial carcinoma in untreated patients and in patients treated by radiotherapy, but in none has an *attempt been made to study the comparability of the two* series or to balance them by selection.

Most workers have compared the mean durations of life from the first symptom (Chandler and Potter 1927, Maxwell and Nicholson 1930, Vinson 1936, Steiner 1940, Tenzel 1941, Shorvon 1947, Harnett 1952). Longer mean duration has been reported in the treated patients, the differences ranging from 1½ months (Steiner 1940) to nine months (Shorvon 1947). LaDue (1955) compared 470 treated patients with 133 untreated and concluded that irradiation led to a 5–15% increase in the survival rate from the start of symptoms; half of the 470 given radiotherapy died during the first year compared with 68% of the untreated. Leddy and Moersch (1940), Farberov and Barlow (1941), and Hilton (1945) reported that treated patients lived longer after diagnosis, as did Widmann (1944), but he rightly commented that

Notes and News

FEEDING IN MENTAL HOSPITALS

A CONFERENCE on feeding in mental hospitals was convened by King Edward s Hospital Fund for London on May 2, under the chairmanship of Prof S J COWELL

Dr T P REES emphasised the psychological value of giving patients in mental hospitals a say in the choice of their food This is achieved at Warlingham Park Hospital by means of weekly meetings between the catering officer and representatives of patients, one from each ward as far as possible

Miss J GUTTERY spoke of the need for a proper balance in menu planning In her experience the dietary often has too much starch and not enough protein, and insufficient attention is paid to balancing of flavours between sharp and bland, appearance and colour, and consistency She urged that breakfasts should always include a protein dish, and that marmalade should be provided daily with breakfast and jam with tea Her conclusion, which was well received, was that food should be purchased according to the requirements of the menu, instead of the menu being fitted to the food purchased

Mr G J STORMONT drew attention to the disproportionate ratio of boiling pans and steaming and draw plate ovens to boiling tops, salamanders, fish fryers, and roasting ovens in the equipment of the average mental hospital kitchen, which of course adversely affects the standard of menu He went on to emphasise the need for correct layout and proper balance of the preparation cooking, and service areas in the main kitchen in mental hospitals, which, owing to the numbers that have to be fed, are usually so large as to make proper supervision difficult, if not impossible A higher standard of cooking would undoubtedly be achieved if all meals were prepared in ward and villa kitchens, but the problem of staffing control would be insuperable in present conditions, and in his view the best compromise would be a kitchen with a maximum output of 1000 meals which would afford scope for sectionalisation and which, under the present Whitley scale, would be large enough for the employment of adequately qualified staff

Mr W G WILSON, speaking mainly in the light of his experience in a mental deficiency hospital, advocated the use of insulated food boxes in preference to electrically heated food trolleys, for the transport of food between kitchen and wards He argued that, intelligently used, insulated food boxes retain heat effectively and at the same time are much cheaper to operate For towing Mr Wilson favoured electric trucks as cleaner steadier, and more manœuverable than petrol driven vehicles

Miss E H JOHNS said that even today there are many difficulties in providing a satisfactory meal service, such as badly equipped ward kitchens, inadequate crockery and cutlery, and, above all, lack of staff Miss Johns urged that priority be given to the upgrading of ward kitchens installation of refrigerators and modern tea making equipment, redecoration and refurnishing of dining room areas, and the provision of more domestic help This last is perhaps the greatest need, in order to reduce the atmosphere of haste which prevails in so many large wards where two or three nurses have to look after seventy or eighty patients, many of whom may require individual attention at meal times Her final plea was for properly appointed tables with tablecloths, tumblers and when the menu requires it, fish knives and forks, so that patients may be encouraged to behave as they would in their own dining rooms

ROYAL COLLEGE OF MIDWIVES

ON May 24 Queen Elizabeth the Queen Mother laid the foundation stone of the college s new and enlarged head quarters at 15, Mansfield Street, London W 1 Since it was founded as the Midwives Institute in 1881 the work of the college has steadily expanded and every year 2000 students now take its courses It receives no Government grant, and to complete the new building and endow it an appeal for £150,000 has been made So far £42,000 has been raised

CASUALTY CENTRES AT SWINDON

Two casualty centres have been opened at the Swindon works of the Western Region of British Railways These centres are to be used for dealing with injuries sustained at work by any of the 12,000 employees in the works and offices, and for renewal of dressings and follow up Each centre comprises a waiting room, first aid treatment room, and rooms for doctor and nurses

GENERAL MEDICAL COUNCIL

THE results of the recent elections for 11 members to sit for five years were as follows

ENGLAND AND WALES

Election of 1 member as a person resident in Wales—The only candidate nominated was Dr W V Howells, who was accordingly elected

Election of 7 other members—The result of the voting was as follows

Dr JANET AITKEN	16,501
Dr H GUY DAIN	15 729
Dr L D CALLANDER	15 277
Dr O C CARTER	14 758
Dr J A BROWN	14 424
Dr S N SCOTT	14 128
Dr E A GREGG	13 936
Dr Stanley Dillon	8615
Dr C T H Whiteside	7911

Dr Aitken, Dr Brown Dr Callander Dr Carter Dr Dain, Dr Gregg, and Dr Noy Scott, were accordingly elected

SCOTLAND

Election of 2 members—Two candidates only were nominated, Dr I D Grant and Dr G W Ireland, who were accordingly elected

IRELAND

Election of 1 member—The result of the voting was as follows

Mr WILLIAM DOOLIN	1376
Dr M B Conlon	485

Mr Doolin was accordingly elected

Royal College of Obstetricians and Gynæcologists

At a meeting of the council held on May 26, with Mr Charles Read, the president, in the chair, the following were elected to the council

As representatives of the fellows—Frank Cook, S W Maslen-Jones J A Stallworthy D M Hart

As representatives of the members—Dorothy M Shotton Matthew Garrey

The following were admitted to the fellowship

V H Barnett Gavin Boyd J E Giesen A D T Govan S W J Harbutt Stanley Henderson Derek Jefferiss N K B Kimbell Parvati Malkani K A McGarrity A H McLennan J D Murdoch E L Nicolson L B Patrick I M Robertson Jane B Roy G J Strean W H Tod

The following were admitted to the membership

E A Agius D G Bonham Reginald Bowman R J M Byrne J K Craig C A Cussen R P De Bond R R Elvidge J W G Evans L A J Evans Jack Eyton Jones Winifred J A Francis C O Fung Kee Fung J G Furber R H Gelb Anne L M Graham R G Harbison, G F W Hossack, G F Jolly, Anna R Kemp Edward Lacy J D Llewellyn Jones F V Mackay John Mander, M D Manion Brian Mensday Nirupama P Nayak R W A Nel J P O Neill G M Parkin H E Reiss L L Relf Freda M Roberts S B Robertson A W Russell Jean M Sharpe P F Venter L M Wolf

Society of Apothecaries of London

At recent examinations the following were successful

M M S A—A S H DeSilva E S Linton B G Pickles A H Saddler I H F Swain, M H Turner

L M S S A—A M Marcus M A C Lyon P L Pratt R S Kjestrup S R Harris H Bezzi G Wood, P J Sandison, J B Middleton R A Harlow H Pambakian J B B Milne D H Brennan C L Wagstaff, B L Dodson W L P Gould P G C Beney A J D Souza D A Gilchrist, D J Dale D G Thomerson B J P Wright G V Lewis, E P Jackson A B Gilmour

Royal College of Physicians of London

On Thursday, July 5, at 5 P M, at the college, Pall Mall East, S W 1, Dr Ivan de Burgh Daly, F R S, will deliver the Bertram Louis Abrahams lecture when his subject will be intrinsic mechanisms of the lung

An R A M C War Memorial

On June 17, at 3 P M at R A M C T A Centre, Upper Chorlton Road, Manchester 16, Major General Thomas Young, colonel commandant of the corps will unveil the R A M C Territorial Army memorial to those who fell in the late war Relatives and past and present members of the R A M C units and attached corps may obtain tickets from the centre

RADIOTHERAPY OF CANCER OF THE LUNG

RESULTS IN A SELECTED GROUP OF CASES

JOSEPH SMART
M A , M D Camb , F R C P
PHYSICIAN, LONDON CHEST HOSPITAL

GWEN HILTON
M B , B Sc Lond , F R C S , F F R
DIRECTOR, RADIOTHERAPY DEPARTMENT, UNIVERSITY COLLEGE HOSPITAL, LONDON

THE treatment of carcinoma of the lung has hitherto been limited to surgical treatment by pneumonectomy or lobectomy, radiotherapy and chemotherapy in inoperable cases, and the combination of surgery and preoperative and postoperative radiotherapy

The five years survival rate of operable cases varies according to different authors The figures given by Bignall and Moon (1955) in a survey of cases operated on at Brompton Hospital and at the London Chest Hospital showed that out of 531 cases there was a 32% over-all survival-rate of five years or longer, which continued to fall gradually to 21% in an approximately ten-year follow up of a limited number of cases The survival-rate following surgical treatment has improved with technique but is still disappointing

The results of radiotherapy in cases considered unsuitable for surgery are even more disappointing Hilton (1935) reports that only 8 of 203 patients selected for radiotherapy survived five years, and at the Christie Hospital, Manchester, Paterson et al (1950) report that 7 of 234 patients survived five years Dobbie (1944) and Shorvon (1947) give an over all survival-rate of up to 2% for five years These figures suggest that the treatment of bronchial carcinoma by X rays alone has no real place, but it must be borne in mind that these figures for X ray treatment refer to cases considered unsuitable for surgery because of spread of disease to the mediastinum and elsewhere Hence it is quite unrealistic to compare the figures with the survival rate for cases operated on

In 1942 one of us (J S) saw a patient with a carcinoma of the bronchus who, on bronchoscopy, was deemed inoperable in view of the involvement of the phrenic nerve and paralysis of the diaphragm, and in whom biopsy showed an undifferentiated carcinoma This case was treated by X rays at St Bartholomew's Hospital, and, although there was gross X-ray fibrosis of the right lung, the patient was still alive, well, and working thirteen years later, when he developed an infection in his fibrotic lung, which was subsequently drained surgically He still remains well and working although there is a permanent drain into his infected space

2 other cases, seen by one of us (G H), were considered by surgeons operable from the purely technical point of view—i e the growth was situated in such a position that pneumonectomy was possible and no secondary deposits were found—but 1 patient refused operation, and the other was unsuitable because of chronic bronchitis Both these patients were treated by radical X-ray treatment and survived for more than five years

In the light of these 3 cases we felt that it would be justifiable to treat a series of selected cases by radiotherapy alone

Selection

Each case was judged suitable on the following grounds the general condition was good the lesion was localised and situated in such a position that surgery could be undertaken, and there was no evidence of mediastinal glandular involvement either clinically radiologically or on bronchoscopy In each case definite histological proof was secured by bronchoscopy and histological section, or by a positive sputum for new growth cells before radiotherapy was started

Material

So far 33 cases have been treated, the first eight years ago Of this series 19 were squamous cell carcinoma and 6 anaplastic carcinoma , in 8 cases the diagnosis was determined by carcinoma cells in the sputum—4 were squamous, and in 4 the precise nature of the cells was not determined, making it impossible to state dogmatically whether these were squamous or anaplastic carcinomas

Preparation

Careful preparation of the patient before irradiation was an essential part of the treatment Measures were taken to improve the general condition and to increase the percentage of hæmoglobin if it was at a low level If necessary, sepsis was dealt with, infected teeth were removed, and infection in the mouth and upper respiratory tract was attended to Infection in the lung was treated by postural drainage and with appropriate antibiotics In some cases several weeks were spent treating the infection before radiotherapy was begun

Supervision

The patients were kept under close medical supervision throughout the course of treatment They were admitted to hospital if possible, especially during the winter They were given a well balanced high calorie diet and full doses of iron and advised to take plenty of rest Sedatives were given to ensure adequate sleep and to suppress any non-productive cough

Radiotherapy

Great care was taken in localising the tumour and assessing the volume to be irradiated, because it was considered that one of the chief causes of failure of radiotherapy in bronchial carcinoma was insufficient dosage to the whole of the cancerous tissue The whole range of radiological methods was used to assess this *The size and disposition of the treatment fields depended on the size of the tumour bearing area* Multiple small field technique was used only if the growth was a squamous carcinoma If the growth was an undifferentiated or oat cell tumour the treatment fields were increased to cover the whole of the mediastinum The inclusion of so large an area was considered necessary because of the almost certain involvement of many of the mediastinal glands

A dose of 5000–5500r was delivered to the tumour if the carcinoma was squamous cell, but only 4000–4500r if it was undifferentiated The length of the treatment and the amount of radiation to be delivered each day was not prearranged at the beginning of the course The patient was seen daily by the radiotherapist, and his temperature chart, pulse rate, respiration rate and general condition were studied before deciding the amount of radiation to be given on that day If there was a rise in temperature or an increase in pulse rate or respiration rate, either the dose was decreased or treatment was suspended for a day or two Great importance was attached to varying the daily dosage according to the *patient's condition* The whole course of treatment usually lasted seven to eight weeks

Follow-up

Of these patients 12 have been followed up for five years or more, 4 of whom are still alive and well 3 of these 4 had squamous cell carcinomas and 1 an anaplastic carcinoma In this same group 1 other patient survived three years 2 survived two years *or more*, and 5 died within the first two years Over this period in a very limited number of cases this gives a survival rate of 33%, which figure is similar to the surgical results

CHANGES IN MEDICAL EDUCATION*

JOHN R ELLIS
MBE, MA, MD Camb, FRCP
ASSISTANT PHYSICIAN TO THE LONDON HOSPITAL, SUB DEAN OF THE LONDON HOSPITAL MEDICAL COLLEGE

(concluded from p 818)

ALL too often attempts to improve medical education are concerned primarily with the curriculum, but the first essential surely, is to define the aim Having translated this into educational objectives, we can then decide what processes of learning the student must employ and what arrangement of his studies will enable him to employ the right process at the right time This arrangement of the right process at the right time is not the curriculum it is an educational plan We know too little about the processes of learning to be sure of what the best plan is, but we know enough to outline the possibilities most likely to be successful

Whatever plan is adopted is, however, no more than an ideal For learning has to be aided by suitable techniques of instruction, and these in their turn require facilities that are bound to vary from school to school and can never be perfect Only when the ideal educational plan is matched against the available facilities does the curriculum emerge In the words of Dr Hale Ham "The curriculum is the course through which the student travels, it is a definition of limitations as well as opportunity"[6] For this reason recommendations confined to the curriculum are tackling medical education at the wrong end and do little more than tinker with the time-table

These then are the essential steps in building up the curriculum

1 A statement of the *aim*—what we are trying to achieve in the period of undergraduate training

2 A formulation of *educational objectives*—what kind of discipline we must teach to achieve it

3 An analysis of the *processes of learning* which the student should employ to master this discipline, together with *techniques of instruction*

4 The framing of an *educational plan* in which these processes and techniques are arranged at the most suitable stages of the student's development

5 Implementation of this plan by translating the theoretical ideal into a feasible *curriculum*

The Aim

The aim of medical education was formerly defined as the preparation of the student for efficient general practice on qualification Though for many years this aim has been obviously unattainable there has been reluctance to admit the fact Even in 1944 the Goodenough Committee said that "the training must fit [students] to enter practice as general practitioners, and must also provide a sound basis upon which those who wish to become teachers and specialists can found the postgraduate training and experience they will require"[7] But since then the practice of medicine has greatly changed, and general practice has itself become clearly a specialised branch of it Within the pattern of the National Health Service postgraduate training for this specialty has developed in the form of trainee assistantship, which most have come to accept as desirable if not essential

It is now clear that the aim of medical education must be to give the student a foundation upon which he can later build a training for any branch of medicine This can be achieved only if he is "groundedly learned" in (1) clinical observation, (2) method of thought, and (3) empirical knowledge, and if he learns how to learn for himself—which is the only basis for lasting efficiency and safety in practice

Abandonment of a comprehensive training in favour of a basic education does not imply a mere reduction in the amount to be learnt It means rather that, throughout medicine, a purely vocational training should give place to education in method of thought and clinical method I do not believe this basic education would be less safe than the present training which is intended to be comprehensive but inevitably leaves out much that has to do with safety

These considerations apply particularly to the general practitioner whose work is affected by advances in almost any part of medicine The standard of medical care in this country depends upon the standard of general practice, and medical schools must regard it as their first duty to ensure the best possible undergraduate education and postgraduate training for their students who will take up general practice, irrespective of whether these are a large or small proportion of the total The sure way to fail in this duty would be to base the undergraduate curriculum on what appears to be the present knowledge needed for general practice, and allow this to be acquired by purely vocational methods But it is also essential that *every* student should see medicine as a whole—both in relation to the patient as an individual and in relation to medical care as it affects the community

The suggestion, often made, that an education which aims to give students an understanding of scientific method is beyond the capacity of most of them is, in my opinion, quite invalid No serious attempt to give it has been made in this country in the past thirty years, though many students have acquired it for themselves "Scientific method" is not a laboratory process but the process of rational and critical thought If we discover that the majority of medical students are indeed incapable of acquiring it, after a university education directed to that end, then we are not attracting suitable people into the profession, and, if we cannot find others more suitable, then there will be no alternative but to have two grades of doctors and alter the pattern of medical practice accordingly

What we have to do, then, is to work out a foundation which will be a sound basis for all forms of medical practice This foundation will continually change, for its content will always be selective, but it will not expand with the additions to medical knowledge The strain of expansion will be transmitted to the postgraduate stage, where it can be relieved—as indeed is already happening—by specialisation within the specialties

Educational Objectives

The first objective is to cultivate in the student the power of *accurate observation* The teaching of clinical observation has always held a high place in English medical education, and the technique of history-taking and of physical examination was a basic feature of the apprenticeship system The clinical introductory course has, I believe, put instruction in this technique on a surer foundation

The second objective is to develop the power of *logical thought* This is necessary for the interpretation of what is observed—although we have to recognise that in clinical medicine it is often effective only when allied to experience

Now there is considerable controversy on when and where the student learns or should learn this habit of logical thought Some hold that it can be learnt only in preclinical or even premedical departments, since these deal with subjects which approximate more nearly to the 11th right rib) to a left oblique approach to the splenic vein (from umbilicus to the bed of the 10th left rib) (fig 1)

* The Goulstonian lectures for 1956 delivered before the Royal College of Physicians on Jan 17 and 19

[6] Ham T H *In* An experiment on Medical Education at Western Reserve University New York 1954 p 13

[7] Report of Interdepartmental Committee on Medical Schools H M Stationery Office 1944 p 173

We concluded that the dorsal position gave us the best exposure and enabled us to obtain standard splenic and portal venograms Our problem was what to do with the arms In these circumstances the arms may be defined as rigid articulated structures interfering with the approach to the side of the body To extend them in the cruciform position was no solution, because that would prevent the vital third assistant from standing headward of the surgeon To fold the arms on the patient's chest in the usual way did not leave enough room for all surgical manipulations, and we wished to be unrestricted

We solved the problem by flexing and raising the patient's arms so that they crossed his face as in the start of the hornpipe dance arms flexed to a right angle and in a plane as nearly as possible perpendicular to the long axis of the body The hands come to rest more or less on opposite shoulders, but small pads may be necessary to prevent pressure on the chin or to support one of the forearms on the upper part of the chest Good fixation can be obtained (as in fig 2) by using elastic adhesive strapping fixed down the dorsal or ulnar surfaces of upper arm, forearm, and hand and extended on to a convenient point of fixation on the side or undersurface of the operating table

Fig 2 shows that the endotracheal tube, the blood-pressure cuff, and the intravenous-infusion needle are concentrated in as small an area as possible The anæsthetist can attend to all the patient's requirements without having to move and therefore favours the position Respiratory movements are in no way impeded There appears to be no risk whatever of any brachial plexus palsy The arms, however, must be prevented from falling upwards if the patient is tipped into the Trendelenburg position

We have now used this position more than 150 times to great advantage Care and a little ingenuity are all that is required in fixing the patient quickly and without special apparatus X-ray cassettes can easily be manipulated in and out of a lateral cassette tunnel—a matter of vital importance in all operations when radiography of either the portal tree or the biliary tract is essential The costal margin is raised, and the inferior angle of the scapula is rotated forward, improving the exposure in the upper abdomen and opening out incisions wh cross the costal margin

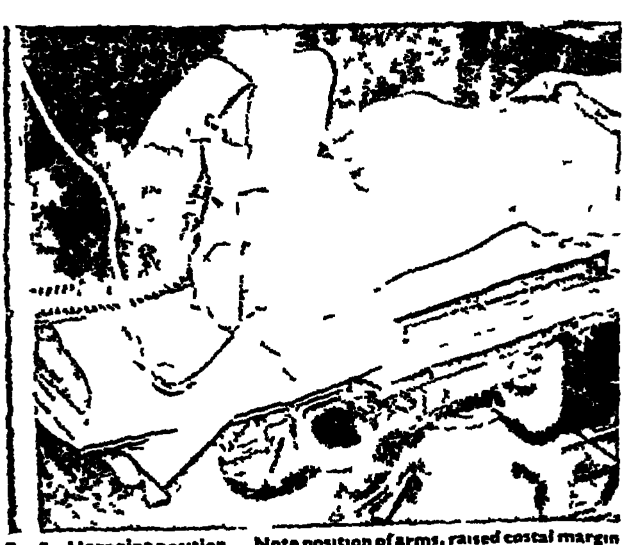

Fig 2—Hornpipe position Note position of arms, raised costal margin forward rotation of scapula freedom of approach from front and sides blood pressure cuff on right arm intravenous needle in dorsum of left hand valves of endotracheal tube, and double cassette tunnel ready for venography Arms are fixed with elastic adhesive strapping and in this figure left hand is supported on small pillow

We have therefore adopted the hornpipe position f many operations as well as those for portal hypertension o for exploration of the biliary passages and for operatio on the pancreas, liver, spleen, cardiac end of the stomac oesophageal hiatus of the diaphragm, and lower end o the oesophagus In operations which are certainly goi to be restricted to one side of the body it is not alwa necessary to have both arms elevated, but it may be a advantage if the X-ray cassette tunnel opens on t opposite side of the patient to the surgeon

Sometimes, after the preliminary investigations of patient with an obliterated portal tree, it has been decid that proximal gastric resection through a left thorac incision is the correct approach In these circumstanc additional rotation of the patient's chest towards th right has been easily effected with the minimum o disturbance by pulling on the left arm and fixing it or on a rest

Summary

Fixation of the patient on the operating-table in position akin to that adopted at the start of the hornpip dance (fig 2) is of great value in operations for port hypertension, &c

Our thanks are due to Dr Ronald Bowen who has giv most of the anæsthetics, to Miss K D Bartlett and th theatre sisters who have helped us with these operation Miss M Rutherford, Miss A F Mallett, Miss J B Chri and Miss E A V Jenkins, and to Mr Henry Dowsett o senior theatre orderly, who has always been of the great help to us Fig 2 is based on a figure which appeared in a article by G H du Boulay and B Green (*Brit J Radi* 1954, 27, 423)

WEIGHT LOSS AND PERNICIOUS ANÆMIA*

A E Read
M D Lond, M R C P
REGISTRAR

Richard Asher
M D Lond, F R C P
PHYSICIAN

CENTRAL MIDDLESEX HOSPITAL, LONDON

Addison (1855), when describing the clinical picture o pernicious anæmia, wrote "The bulkiness of the genera frame and the obesity often present a most strikin contrast to the failure and exhaustion observable in ever other respect The general frame becomes flabb rather than wasted"

Most clinicians and textbooks concur and do no mention loss of flesh as prominent in addisonian anæmi Students are taught that most patients with the dis are well covered or obese—indeed many are How ever it is not uncommon to find a history of lo weight, and clinical examination often confirms th I some cases of pernicious anæmia this weight loss may b quite alarming and may lead the clinician to make anothe diagnosis, usually malignant disease

Jones (1938) described 76 patients with pernicio anæmia 42 of these had lost weight when admitted this loss ranging from 2 to 12% of their usual weight Further, he showed that a gain in weight followed treatment (in those days liver by intramuscular injectio in 28 of these 42 patients

It is our purpose to re-emphasise the importance o these observations and to stress that weight lo i addisonian anæmia is common As it will be seen—th weight loss misled the clinician on several occasions a

---

* Read at a meeting of the Middlesex County Medical S at the Central Middlesex Hospital on Dec 9, 1955

Such an introduction must be very carefully planned It does not aim at and must not result in a hazy picture of the whole—vague principles and half-facts What is learnt must be understood, and be definite

I would not at this stage include elaborate schemes to increase the student's awareness that man is a social animal, a member of a family and of a society Such schemes are used in American schools, but I doubt whether they have real value at this stage The difference in age of students and ways of life in the two countries have also to be remembered Nevertheless, it is very important that the student should begin to consider the social aspect of medicine To this end it would perhaps be worth setting him certain tasks—such as making a survey of local industry or health services

This first stage would require, perhaps, one year divided into three terms as now—or two longer terms

Study of the Abnormal

Study of the causes and effect of variation from normal would be based on the departments of bacteriology, morbid anatomy, psychiatry, and pharmacology Clinical problems should be used as illustrations, and the natural link between infectious disease and bacteriology be exploited

Again teaching would be integrated and experience systematised Special pathology would not be included I think one term would be enough

Introduction to Clinical Method

Here I have in mind the present clinical introductory course in a modified form, lasting one term—i e, slightly shorter than at present Six weeks of applied anatomy and physiology would be devoted to learning the technique of clinical observation, the student being concerned only with the methods of obtaining evidence In this he would be instructed, and his instructors would not attempt to teach him to interpret evidence, but only how to elicit it In the next four weeks he would be introduced to interpretation by systematised demonstrations combining medicine and pathology In this period, which would prepare him for work in the wards, he would require teaching, as opposed to instruction He must be helped to bring his own reason to bear on the problems presented

Practice of Clinical Method

After this instruction in clinical method, the student should have the opportunity to practise it under supervision—i e, by an inpatient clerkship and dressership totalling six months This is the place in the plan where a combined surgical and medical firm could be attempted I am not certain that it is practicable, but it should be tried

Stage of Consolidation

At the end of this six-month period of unsystematic exposure to clinical experience, during which much knowledge would have been gained, I would present the student with a "survey of human disease" combining the study of "special pathology," social pathology, and the systematic study of medicine

General Experience

I would then send him into the wards for six months for further general experience He should have responsibility for clinical laboratory investigation, and his work should be closely integrated with that of the firm, so that he may learn the team work of medicine by being a member of the team Though I should prefer his medical firm to be as general as possible, I would let him join any surgical department that he wished I would not worry him with lectures in this period, and I would like him to live in or near the hospital

Special Experience

The student would now be in his fourth year at medical school—for holidays must be added to the times I have stated In this year he should hold an appointment in midwifery and pædiatrics (with further teaching from the department of anatomy) and an appointment in the outpatient department Together these would cover ten months In this year and in the last there would be a free period of two months in which the student could be attached to two special departments of his choice, one in each year He would attend the outpatient clinics of other departments

Practice under Supervision

In this five-year plan there are now six months unallocated, and these should be for the student a stage of practice under supervision—three months in hospital and three months outside The hospital appointment I envisage would be to a general medical outpatient clinic, served by students and supervised by teachers I believe it would be of inestimable educational value and perfectly feasible It would be complementary to the outside appointment, which would be in a university health centre, such as that in Edinburgh, but with more provision for student service In this way the student would, under the supervision of his own school, learn something of practice in both fields of medicine—that in hospital and that outside—and of the links between the two He would learn by participation and not by observing This would be of incomparably greater value than any number of weeks spent "seeing and hearing" what a general practitioner does By this means, too, the school could test his practical ability—a form of assessment we now lack

The Tutorial System

At all stages teaching should be integrated by a tutorial system The duty of the tutor is to inspire and guide the student to bring his own intelligence, previous education, industry, and character to bear on rewarding work He need not necessarily be the student's philosopher and friend, but he must be his guide, and he can only guide him well if he really knows him

The tutorial system is the solution to the problem of the large teaching staff and the groups of unknown students It should enable us to re-create apprenticeship, but an apprenticeship suited to modern medicine —not concerned with passing on the "tricks of the trade" but contriving to make the student understand by his own efforts, and thus acquire both lasting knowledge and the ability to go on learning

The tutor can guide the student in three main ways

(1) In his reading, especially from original work

(2) In his writing Few students can learn to think if they do not regularly transmit their thoughts to paper

(3) In his follow-up of selected patients This is now essential, and the most effective method is for the tutor to select patients from those encountered in early clinical appointments

The work of tutoring should not be arduous, for it is done more by thinking than by talking It can be done well only by those who are sincerely interested in the education of students, who are able to give it the time required, and who have professional experience and ability

Methods of Assessment

An educational plan, such as I have outlined, must include a system of assessment, and this must be integrated with the curriculum itself Examinations are at present the most powerful of all the incentives determining the student's method of learning, and under present conditions their influence is unhealthy Though they are indispensable as one form of assessment, they must be related at all stages to the educational plan Furthermore, other forms of assessment, based on continuous observation of the student's progress, are more reliable and provide a better stimulus to proper habits of learning But under our present system, no form of progressive assessment is possible if barium meals are to be done in patients misdiagnosed as having malignant disease these are much better tolerated after, than before, the appropriate therapy

It is interesting to speculate as to the cause of weight loss in these patients Vitamin B_{12} has been shown experimentally to act as a "growth factor" It has also been used with success by some workers (Larcomb et al 1954) in the treatment of underweight schoolchildren Thus one might expect the depletion of vitamin B_{12} in pernicious anæmia to cause loss of weight, and it is difficult to see why this is not more common and more severe

We do not pretend to have produced anything new or unusual in this paper, but we believe that the recognition of weight loss as a complication of pernicious anæmia is both of interest and of importance

A SHORT SMALL INTESTINE ASSOCIATED WITH FIBROSIS OF THE LIVER

C Raeburn

M R C S

MORBID ANATOMIST

A J Brafield

M B Madras, D C P, D Path

ASSISTANT PATHOLOGIST

AREA LABORATORY, WHIPPS CROSS HOSPITAL, LONDON

THERE is considerable experimental and clinical evidence that dietary deficiency or imbalance may either cause liver disease or influence unfavourably the progress of non-nutritional liver disease

Himsworth and Glynn (1944) showed that both massive hepatic necrosis and diffuse hepatic fibrosis (portal cirrhosis) could be produced experimentally in laboratory animals by an abnormal diet, massive necrosis by methionine or cystine deficiency and diffuse fibrosis by a high fat diet with a moderate amount of protein Diffuse fibrosis follows severe fatty change in the liver cells, it develops around the portal tracts and central veins and is essentially a replacement fibrosis The fibrosis of congestive heart-failure develops in a similar manner (Day and Armstrong 1940) from the portal tracts and from the region of the central vein

Dietetic liver disease in laboratory animals is most easily produced in young males (Farber et al 1951) and may be enhanced by the administration of thyroid gland (Beveridge 1954) retarded by giving antibiotics (Gyorgy et al 1951), and even prevented by rearing the animals in strictly aseptic conditions from the moment of birth (Gyorgy 1954)

In man the tropical and subtropical syndromes of dietetic liver disease are probably closely related to the diffuse fibrosis following fatty degeneration seen in the rat, but in temperate climates nutritional liver disease is probably nearly always due to protein deficiency caused by the effects of extrahepatic disease or of alcoholism the latter a more complex situation in which toxic and nutritional factors combine

Hepatic fatty change followed by fibrosis is stated to be often associated with ulcerative colitis Kimmelstiel et al (1952) put the frequency at 40% The contributory factors in this disease are dietary restriction, impaired intestinal absorption, blood loss and possibly bacteræmia

A similar situation might well arise after extensive resection of small intestine, but it seems clear that the intestine is more than adequate in area considera lengths may be removed with impunity, and if surge are alert to the possibility of intestinal insufficie after very extensive operation the diet will reinforced

Hypoplasia of the intestine has not been mention and for that reason the following cases are descri The measurements taken were from the duodenoje flexure to the cæcum

Case-reports

Case 1 —A woman, aged 72, was admitted in coma had complained of headaches and had not been quite h several years About a year previously she had been tr for generalised œdema and given digoxin and mersaly for the last few weeks she had had vomiting swelling of legs, and enlarging abdomen She died three days a admission, deepening coma, ascites, œdema and albumi were the only positive findings

Necropsy Findings —A wasted and œdematous woman w bilateral pleural adhesions and severe œdema of the lu The liver weighed 28 oz and was shrunken and fibrous w regeneration nodules throughout The spleen was firm of normal size The peritoneal cavity had been tapped contained only two pints of fluid The jejunum and il *together measured 11 ft but appeared otherwise normal* organs and tissues were œdematous

Histology —The liver showed severe fibrosis with prolif tion of bile ducts and an abundance of chronic inflamma cells in the portal tracts There were changes due to po obstruction in the spleen, and the jejunum and ileum contai a few areas of neutrophil leucocytic infiltration in the muc

Case 2 —A woman, aged 62, complained of lassitu weakness, and diarrhœa of about two months duration had been vaguely unwell for five years, and four ye previously she had been investigated because of attack diarrhœa, and her blood pressure had been found to 230/130 mm Hg, her liver had been palpable She *presented with severe anæmia (Hb 44%) and ascites* condition rapidly deteriorated and she died

Necropsy Findings —A pallid and wasted woman jaundice Venules on the nose and prolapsed hæmorrho 6 pints of fluid in the peritoneum The liver weighed 32 and showed diffuse fibrosis There were scanty regenerati nodules about 0 5 cm in diameter The spleen weighed 10 The other organs showed changes due to anæmia The sm *intestine measured 6 ft and was otherwise normal*

Histology —Fibrosis of the liver with regeneration of li cells and bile ducts and infiltration of the fibrous ti inflammatory cells The spleen showed a myeloid reacti in addition to changes due to portal obstruction Sections the intestine were normal but for slight œdema

Case 3 —A woman, aged 59, complained of stead increasing lassitude, loss of appetite, loss of weight a occasional diarrhœa for more than a year Four siblings a four children were perfectly healthy Her liver and sp were impalpable, but she had severe ascites distension abdominal veins moderate œdema, and severe seconda anæmia (Hb 34%) She died within two days of admission

Necropsy Findings —A sallow wasted woman with œde of the legs and distended abdomen Ascites of 12 pi The liver weighed 32 oz, its capsule was wrinkled and secti showed diffuse fibrosis, the pattern being distinctly coar the right lobe The spleen was firm and weighed 6 oz T other organs showed changes due to anæmia and œdema a *there was terminal bronchopneumonia* The small intesti measured 4½ ft jejunum 3 ft, and ileum 1½ ft Th was no evidence of any disease to account for this extraordi appearance The marrow of the vertebræ showed a regeneration

Histology —The liver showed diffuse portal fibrosis a centrilobular necrosis, with some regeneration of bile du and scattered inflammatory cells but there was practicall no regeneration of liver cells The spleen showed the due to portal obstruction and a slight myeloid reaction T jejunum and ileum showed subacute inflammation confi to the mucosa, and there was chronic inflammation of t mucosa of the colon Active hæmopoiesis in bone marr of vertebræ

Case 4 —A woman, aged 80, was admitted in a confu state and incontinent after a short period of coma are many others which require careful study and positive action if the selective clinical experience so essential to education is to be realised. At some hospitals population changes have adversely affected the clientele. The establishment of well equipped and well staffed regional-board hospitals has led to the diversion of acute emergencies, and of patients with common and easily treated ailments, away from the teaching hospitals. The number of children needing hospital treatment has fallen dramatically in all areas, and the numbers of the aged and chronic sick have increased. To maintain adequate turnover of patients at teaching hospitals the arrangements under which they can be discharged or transferred require further attention. In future the trend of hospital activities is likely to be towards increasing outpatient diagnosis and treatment and diminishing inpatient care—the latter being predominantly surgical. The possibility of much of the teaching hospital's work being diverted to health centres must be envisaged, together with an increase in domiciliary medical care. All these factors must be taken into account in working out the educational plan. Our greatest need is for a teaching hospital to be based on the community, and where the community health services lead, the teaching must to a large extent follow. Only if we have our educational objectives firmly established and our plan clearly conceived can we lay down and preserve the foundation which we need.

Method of Reform

Obviously we cannot present a clear cut alternative to our present system of medical education, in the shape of a well defined, universally applicable curriculum which any and every medical school can adopt without difficulty.

I have said that any medical school in the country could at once take steps to work out its own curriculum on the basis of an educational plan. It should do so, and plan, as an integral part of it, the examinations and other forms of assessment required. It should define and choose the teaching team it would use. It should go further and devise means for the improvement in student-teacher contacts that is vital to the success of medical education. It should integrate the provisional-registration appointments with the rest of the curriculum. Lastly, it should set out to evaluate the results; for only by evaluation can adjustment be made, efficiency maintained, and progress secured.

All this can and must be done by the medical school. It cannot be done for it by any other body. And it can be done effectively only by democratic method—a representative planning committee. For even the best curriculum will become largely ineffectual unless the teachers not only picture it clearly in its entirety but are also aware of why it differs from the ideal plan.

Democratic methods are slow. The planning committee of a medical school could not make progress by occasional meetings. Hard work and much time are required. But the task is urgent and necessary because medical education can no longer safely be a by-product of other medical work.

No school will devote the time and concerted effort that are required unless it is given a strong stimulus to do so. And the stimulus is unlikely to act without the knowledge that the responsibility for making, and continuing to make, improvements rests upon the school itself.

Today the existence of minimal requirements which, though "recommended" by the General Medical Council have come to be accepted as regulations, together with rigid examinations, stand as a bar to those who wish to make changes. To many they are a disincentive to question what change is required, and by the remainder they can be used as an excuse.

"At this juncture," I quote from a recent memorandum of the Royal College of Physicians, "no detailed guidance by the General Medical Council could do so much good as a relaxation of their 'control by prescription,' which would encourage—even oblige—teaching authorities to consider their curricula afresh."

The Medical Act of 1950 gave the General Medical Council for the first time the power to inspect medical schools. Thus a new way of meeting their statutory obligations—that of inspection of the medical school (its curriculum and examination system being seen as a whole)—is now open to the council.

Freedom to experiment, and greater freedom to make improvements, could therefore be given to universities and licensing bodies if the council were now to lay down the broad aim of medical education but place on those authorities the responsibility for planning a satisfactory curriculum and giving a satisfactory education. Since nearly half the medical schools of the country are within one university, it is clearly essential that London University should not only set up a planning committee at the highest level but also should transmit the same freedom and stimulus to its twelve medical schools.

This, I am certain, is the first step which has to be taken in the reform of medical education. When it has been taken, however, we shall—more even than now—come up against the hard reality that facilities for teaching urgently need to be improved and new ones provided. I am quite sure that no medical school can meet these needs by its own unaided efforts. If it were possible to do so, much more would already have been done.

As I have shown, there are three main requirements—accommodation, teachers, and clinical facilities. The first demands that the highest priority must be given by the teaching hospitals of the National Health Service to providing the physical conditions necessary for medical education. The second demands arrangements between the Ministry of Health and the universities by which some at least of the clinical teachers can devote more time to teaching and research in the teaching hospitals, so that their work, for the health service and in private practice, is centred on the place where they are teaching. (If long term research is to continue and the needs of education be met, the universities must also increase the number of senior full time teachers.) The third requirement—the most serious of all—demands action by the Ministry of Health to promote the formation, especially in London, of teaching hospital groups, with the simultaneous establishment of regional consultant hospital centres. The teaching-hospital group must be such that it can give patients care of the highest standard (which involves specialisation), can undertake research, and can admit patients with acute and common conditions from the community around it. Its size and cohesion must be such that the influence of the non-clinical departments of the university can permeate the whole.

These requirements can be met only if there is, in all regions, an authoritative medical advisory committee, which will secure collaboration between teaching and regional board hospitals. The establishment of university health centres, with staff holding university appointments, is a new (but in my opinion essential) requirement, in which again the universities and the Ministry of Health must combine.

Freedom of medical schools to experiment is the first step in the reform of medical education, and provision of proper facilities is the second. It is not, however, the last. For medical education must never again be allowed to fall behind and lose touch with the advance of medicine and change in practice. Not only must it keep up to date; it must anticipate events, and not be the frustrated victim of their effects. Indeed, medical education must initiate trends. It alone can really ensure that the prevention of disease becomes increasingly the aim and results were rather surprising both patients felt better, the signs of myxœdema diminished, and the blood-cholesterol level fell, but the basal metabolic rate (B M R) remained unchanged at a low level These observations suggested that triac might differ qualitatively in its physiological effects from thyroxine and triiodothyronine However, experience with another case of myxœdema (Trotter 1955) showed that oral triac could raise the B M R in addition to relieving the symptoms of myxœdema and depressing the blood cholesterol level But subsequently it was found that, when this patient was treated with thyroxine, his blood-cholesterol level remained not much below its original level in spite of a greater increase in B M R than had been obtained with triac (fig 1) This again raised the possibility that the action of triac might differ from that of thyroxine, though it was clear that the difference could not be absolute But it remained possible that triac could have a relatively greater action on the blood cholesterol level than on the B M R, compared with thyroxine This possibility would not only be of theoretical interest but might also afford a means of lowering the blood cholesterol levels of euthyroid people without causing side effects

Some further results are now reported In 2 other cases of myxœdema an attempt was made to compare the effects of triac and of triiodothyronine on the B M R and the blood cholesterol levels Triac was also given to 3 euthyroid people to discover whether the blood-cholesterol level can be lowered without an increase in the B M R In addition, the short-term effect of triac on the blood cholesterol level was investigated in 15 other euthyroid people, but without estimation of the B M R, and 12 other comparable patients were similarly treated with triiodothyronine

Methods

A standard apparatus of Benedict-Roth type was used for B M R determinations, using Aub-Dubois standards The patients spent the previous night in hospital in all cases

The plasma cholesterol level was estimated by a modification of the method of Sackett (1925) The patients were fasting when the blood was taken Triac, triiodothyronine, and thyroxine were administered orally as tablets in twice daily doses

Material

Cases of Myxœdema

Case 1 has been described previously (Trotter 1955)

Case 2 —A man, aged 53, had noticed during the past two years increasing fatigue and slowness He had become sensitive to cold, and his voice had become hoarse and his skin rough On examination he showed much puffiness round his eyes and his skin was dry and thickened His thyroid gland was impalpable The uptake of radio iodine was 18% in twenty four hours and the initial B M R −31%

Case 3 —A woman aged 73 had been diagnosed, ten years previously as having pernicious anæmia, which responded well to liver injections and at the time of admission was well controlled by fortnightly injections of vitamin B_{12} Her hæmoglobin was 94% During the past two years she had become increasingly sensitive to cold and her hair was coming out Her voice was hoarse and her skin rough and dry Her thyroid gland was impalpable The uptake of radio iodine was 8% in twenty four hours and the initial B M R −32%

Case 4 —A woman aged 63 complained of swelling of the face and increased sensitivity to cold for the past six weeks Her hair had been coming out for the last few years Her face was bloated and her skin dry She had severe hypertension (blood pressure 210/150 mm Hg) and radiographs of her chest showed enlargement of the left ventricle Electrocardiography showed right bundle branch block The uptake of radio iodine was 7 5% of the dose at twenty four hours The plasma cholesterol level (determined before admission) was 406 mg per 100 ml and the initial B M R −30%

Euthyroid Patients

Case 5 —A man, aged 72, had had thyrotoxicosis in 19 This was treated by subtotal thyroidectomy There was subsequent recurrence of symptoms the thyroid gland was impalpable, and there was no clinical evidence of myxœdema In 1950 he started to get precordial pain on exertion and in 1953 he also developed typical intermittent claudication In 1951 his plasma cholesterol level was 360 mg per 100 ml Thyroxine up to 0 5 mg daily had no clinical effect and did not produce any definite change in the plasma cholesterol level In 1953 his plasma cholesterol level was 495 mg per 100 ml, he was not having any treatment at this time Before triac was started he could walk only slowly, being limited both by intermittent claudication and by anginal pain He was somewhat obese, though otherwise normal in appearance Radiography showed that his heart was normal in size Electrocardiography showed much depression of the ST segment in lead V_5 The uptake of radio iodine was 28% in twenty four hours and the initial B M R +7% and −6%

Case 6 —A man aged 57, had had coronary thrombosis in 1947 and in 1950, with electrocardiographic changes on both occasions In 1953 he was readmitted because of a sudden attack of precordial pain, but electrocardiography did not suggest that a further infarct had developed Since his first thrombosis he had been subject to precordial pain, both at rest and on exertion, but the description did not sound typical of anginal attacks There were no abnormal findings on physical examination, except that the blood pressure was 164/100 mm Hg Before the start of triac therapy the uptake of radio iodine was 10% and 11% in twenty four hours (measured on separate occasions) The low uptake could not be explained by any drugs he was taking He did not appear at all myxœdematous and the B M R before the start of treatment was −6%, −5%, and +1% (readings on separate days) and the plasma cholesterol level 269 mg per 100 ml

Case 7 —A man, aged 56 had been admitted fifteen months previously with a typical attack of coronary thrombosis and electrocardiographic changes characteristic of a recent anterior infarction Before triac was started his only symptom was mild breathlessness on exertion There were no abnormal physical findings Electrocardiography showed deeply inverted T waves in lead V_3 The uptake of radio iodine was 41% in twenty four hours and the initial B M R −10% and −12% The initial plasma cholesterol level was high (365 mg per 100 ml), but the absence of clinical signs and the normal uptake of radio iodine were considered to exclude myxœdema

The remaining euthyroid patients were all women with slight to moderate goitres without evidence of either thyrotoxicosis or myxœdema

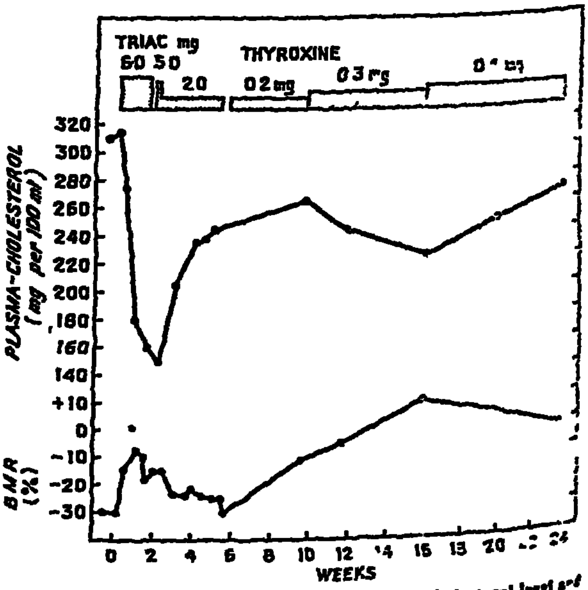

Fig 1—Effect of triac and of thyroxine on blood-cholesterol level and B M R in myxœdema

Method

The patients studied had either advanced pneumoconiosis or bronchitis and emphysema, and breathlessness prevented them from walking more than a few yards Some were inpatients at the time of the investigation The remainder were identified as having breathlessness grade 4 or 5 (Fletcher 1952) from the records of patients previously discharged from our ward, and they were invited to come in again for this investigation Some of the patients were found to benefit from chemotherapy, antispasmodics, postural drainage, or diuretics before investigation This reduced factors other than oxygen which might influence walking performance and improved the repeatability of the results If oxygen proved to be beneficial under these conditions it would be likely to be more rather than less effective under the conditions in which these patients normally exist

Exercise performance was assessed on a treadmill, the speed and slope of the belt being adjusted so that, breathing air, the man could walk for two minutes before stopping because of breathlessness A constant time, rather than a constant work load, was selected because the degree of activity producing breathlessness varied from one patient to another The period was chosen to reproduce conditions where a patient is repeatedly obliged to pause for breath on exertion In addition, the effect of oxygen in increasing the duration of maximal exercise in healthy people is not apparent unless the exercise is at least of this duration (Christensen et al 1934)

Once these conditions had been established, the walking time while the patient was breathing air and oxygen was determined, the gases (of composition unknown to the patient) being delivered through a humidifier to either a mask or a mouthpiece through a demand system operating at a low suction Each walk was continued until the patient chose to "take a spell" because of breathlessness, or for five minutes, whichever was the shorter time Five minutes was chosen because a man who can walk for this time without incapacitating breathlessness is likely to be able to continue longer, and his time of stopping may then be more influenced by fatigue or other factors

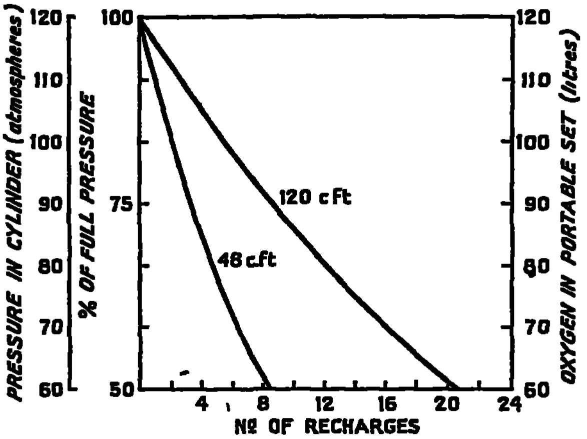

Fig 3—Relationship between number of recharges and pressure in charging cylinder

In some cases the arterial oxygen saturation was recorded with an ear oximeter previously calibrated against samples of arterial blood collected simultaneously The ventilation was measured on a low resistance gas-meter The portable oxygen sets were tested by some of the patients in hospital, and in a few cases they were lent for trial at home Visits were made to each patient's home at intervals of not longer than four weeks, in addition to weekly visits by their practitioners

Results

Effect of Oxygen in Increasing Exercise Ability

29 patients in clinical grades 4 or 5 were studied, 28 of them had been coalminers, and 18 had pneumoconiosis X ray category 2 or above on the International Classification (1950) (Cochrane et al 1951, Fletcher 1955) All these patients gave a history of chronic bronchitis and had emphysema and cor pulmonale 17 of them were admitted for treatment of acute exacerbations of their

TABLE I—EFFECT OF ADMINISTRATION OF THREE DRUGS IN DAILY DOSES FOR TWO WEEKS ON UPTAKE OF RADIO IODINE, MEASURED BY NECK/THIGH RATIO TWO HOURS AFTER TRACER DOSE

Drug	Dose (mg daily)	No. of patients	Initial neck/thigh ratio (mean ± S.E.)	Final neck/thigh ratio (mean ± S.E.)
Thyroxine	0·4	13	7·0 ± 1·02	2·7 ± 0·42
Triiodothyronine	0·04	4	8·2 ± 1·51	2·7 ± 0·45
Triiodothyronine	0·08	4	7·6 ± 2·42	2·4 ± 0·84
Triac	2·0	7	8·1 ± 1·89	1·5 ± 0·18
Triac	3·0	4	5·1 ± 0·83	2·3 ± 0·73
Triac	4·0	4	8·7 ± 1·76	1·7 ± 0·18
Controls (dummy tablets)		3	6·3 ± 2·07	6·1 ± 1·17

It seems therefore that in these 2 cases of myxœdema triac has about a seventy-fifth of the activity of triiodothyronine, as regards both elevation of the B.M.R. and depression of the blood-cholesterol level. Further comparisons of triac, triiodothyronine, and also thyroxine are being made in both these patients.

Euthyroid Patients

In the 3 euthyroid subjects whose B.M.R. were also measured the dose of triac was initially 1 mg daily and was raised gradually to 3 or 4 mg daily. This was done because it was anticipated that triac would inhibit the production of thyroid stimulating hormone by the pituitary gland. The patient's own thyroid would then cease to secrete and he would require larger doses of exogenous hormone to produce effects after the stores of endogenous hormone had been exhausted. In case 4 the initial radio iodine uptake of 28% was reduced to 3% after three weeks' treatment with triac (1 mg daily for a week followed by 2 mg daily for two weeks). In case 6 the initial uptake of 41% was reduced to 4% after six weeks' treatment (1 mg daily for four weeks followed by 2 mg daily for two weeks). In 15 cases of non-toxic goitre treated with triac for two weeks measurements of the ratio of neck count to thigh count at two hours after a tracer dose of radio iodine were available ("neck/thigh ratio"). These figures were comparable to those found by Morgans et al. (1952) in cases of non-toxic goitre treated with 0·4 mg of L-thyroxine for two weeks. In table I the two series have been compared, together with some results in comparable cases treated with two different dosages of triiodothyronine. It will be seen that the degree of inhibition obtained with 2–4 mg of triac daily is at least as large as with 0·40 mg of thyroxine or 0·04–0·08 mg of triiodothyronine. This suggests at first sight that triac is much more potent (relative to triiodothyronine) than appeared from the effects of the two drugs on the blood-cholesterol level and the B.M.R. in the 2 cases of myxœdema; but in interpreting these figures one must take account of the possibility that much of the iodine contained in triac may be released sooner or later as iodide. Although the amount of iodide released by 0·4 mg of thyroxine is insufficient to affect the radio iodine uptake (Morgans et al. 1952), the amount released by 2 mg of triac might well depress the uptake to some extent. Nevertheless it seems reasonable to assume that at least part of the decrease in uptake is attributable to the inhibition of production of thyroid stimulating hormone because such inhibition has been shown in animals (Pitt-Rivers 1953). If this is so, it would be expected that the effects of a constant dose of triac on the blood cholesterol level and metabolism would be greatest when administration is first started, and would decrease progressively as the patient's own contribution of thyroid hormone declines. This view is supported by observations on the blood cholesterol levels of 3 patients with non-toxic goitre, treated for up to ten weeks with a constant dose of 2 mg of triac daily (fig. 6). The blood cholesterol levels were initially depressed but gradually reverted towards their original levels.

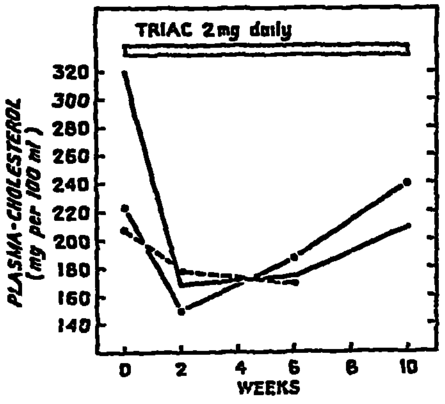

Fig. 6—Effect of constant dose of triac 1 mg twice daily on blood-cholesterol levels in 3 euthyroid patients.

The results obtained by a gradual increase in triac dosage are shown in figs. 7–9 (cases 5–7). In all 3 cases the blood cholesterol level fell gradually over months. In case 5 (fig. 7) the B.M.R. rose slightly when the dose was raised from 2 to 3 mg daily but it subsided after a few weeks without a change of dose. This minor rise of the B.M.R. (maximum +8%) did not appear to inconvenience the patient although he has severe angina of effort. Electrocardiography on six occasions while he was taking triac showed no significant change. The small fluctuations in the B.M.R. observed with cases 6 and 7 were not considered to be significant and were not associated with any change in symptoms. Pulse-rate and blood pressure did not alter significantly in any of the 3 patients. Their body weights fell by 2–5 lb. over the period indicated in the charts.

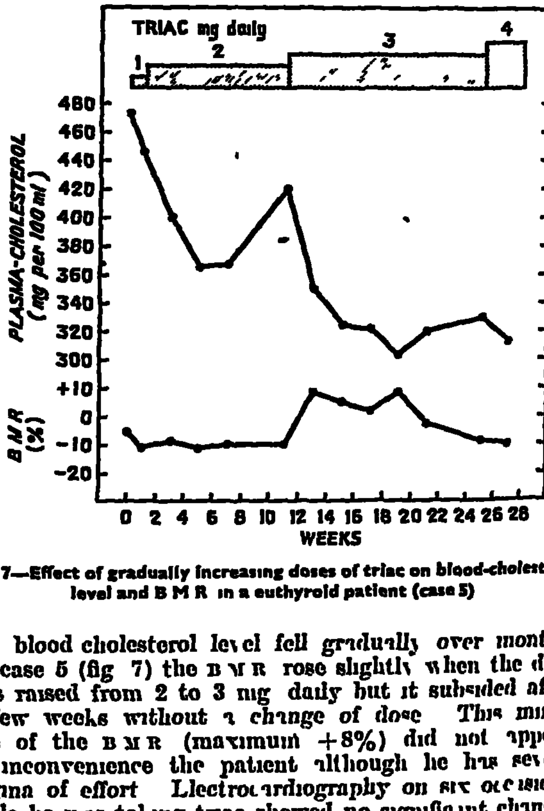

Fig. 7—Effect of gradually increasing doses of triac on blood-cholesterol level and B.M.R. in a euthyroid patient (case 5).

Triac was also given for two weeks to 15 women with small non-toxic goitres. The plasma cholesterol level was estimated in the fasting state at the beginning and end of the two weeks. 12 similar patients were treated for the same length of time with triiodothyronine in doses of 0·04 and 0·08 mg daily. In addition, 4 similar patients were given dummy tablets for two weeks. The results are shown in table II. It will be seen that doses of 2, 3, or 4 mg of triac daily depressed the plasma cholesterol level by about 26%. All 15 patients treated those of the first experiment in suggesting that the breathing of 30% oxygen instead of air significantly increases exercise performance. With higher oxygen concentrations there was a further increase, but, since the patients were then often able to walk until stopped at the end of five minutes (or five and a half minutes in case 7 *), the relative value of 50% and 100% oxygen could not be inferred directly. However, the exercise ventilations while breathing these two concentrations of oxygen were almost identical (mean 22.3 and 21.9 litres a minute), which suggested that the two gases were equally effective.

Increasing the oxygen flow from 2 to 4 litres a minute when an oxygen mask was used also increased exercise performance. However, the walking distance of the 1st patient, breathing 2 litres of oxygen a minute through a mask of the B.L.B. type, was apparently less, and that of the second 2 patients, breathing 3 litres of oxygen a minute through a mouthpiece adjusted to have the volume and flow characteristics of a mask, was significantly less, than that achieved while breathing 30% oxygen. The calculated average inspired oxygen concentrations were similar, and oximeter readings indicated that the blood was as effectively oxygenated. We thought that the difference was caused by the respiratory embarrassment produced by the accumulation of carbon dioxide in the rebreathing bag. Support for this view was obtained by inserting a valve in the neck of the bag. This reduced the ventilation on average by 4 litres a minute in both healthy people and patients with chronic lung disease at rest and during exercise (Cotes and Merrick 1956).

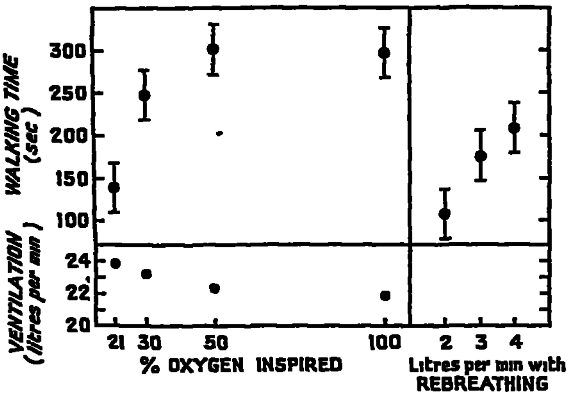

Fig 5—Effect of oxygen on walking time (cases 4 and 7)

The relative effectiveness of air, 30% and 50% oxygen in nitrogen, and of 3 litres a minute fed into a modified mouthpiece with and without rebreathing was assessed in 3 patients (cases 8, 12, and 26). The results have been combined in fig 6. They confirm that these patients can walk further breathing 30% oxygen than breathing air. 30% oxygen was, however, significantly less effective than 50% oxygen in increasing exercise ability, and the exercise ventilation was in every case higher when the patient was breathing the lower oxygen concentration. 3 litres of oxygen a minute through a mask with a check valve in the neck of the bag enabled the patients to walk significantly further than under the same conditions but without the valve; however, even after this modification, oxygen delivered to a mask proved rather less effective than the corresponding oxygen mixture.

We conclude that the substitution of 30% oxygen for inspired air much increases exercise ability in some patients. With 50% oxygen there is a further increase but small in proportion to the increased amount of oxygen required. The effect of 30% oxygen can be reproduced by 4 litres of oxygen a minute delivered to a well fitting oxygen mask with an oxygen reservoir bag and check valve to prevent rebreathing. This combination is the optimum for a portable oxygen supply for use in these circumstances.

TABLE III—ESTIMATED COST OF MAINTAINING THE ALVEOLAR OXYGEN CONCENTRATION AT 35% FOR A WEEK

—	Oxygen flow (litres/min.)	Cost per week		
		Equipment (pence)	Oxygen (pence)	Total (£)

* Including an allowance for flushing

Portable oxygen Therapy

Exercise ability was much increased by breathing oxygen in 22 of the 29 patients in the series, and we think that, if temperament and other factors are taken into account, about half might benefit by portable oxygen therapy. 4 patients (cases 8, 12, 21, and 26) have been fitted with oxygen masks incorporating a non-return valve to prevent rebreathing and have been provided with oxygen sets adjusted to deliver 4 litres of oxygen a minute. In each case a daily charge of oxygen has enabled a man, previously virtually immobilised by breathlessness, to move about the house and to walk out to sit in the garden. No adverse effects have so far been observed. These preliminary trials are continuing. An extended trial of portable oxygen equipment might be worth while when the improved equipment with detachable oxygen bottles becomes available.

Domiciliary Oxygen Therapy

More oxygen is supplied for home use than is probably generally realised. During 1955 a third of all chemists in Wales and Monmouthshire (population 2,600,000) were asked for oxygen or oxygen equipment, which was supplied on prescription to 860 patients. The consumption in April that year amounted to 750 of the 48 c.ft. cylinders. On April 30, 134 patients were using oxygen, of whom 83 had done so for more than three months and 10 for more than three years.

The quantity of oxygen used at home is small in comparison with that supplied to hospitals, however, litre for litre, domiciliary oxygen is at present four times as expensive (table III) and contributes appreciably towards the total oxygen cost. The expense of distributing domiciliary oxygen might be reduced by the substi-

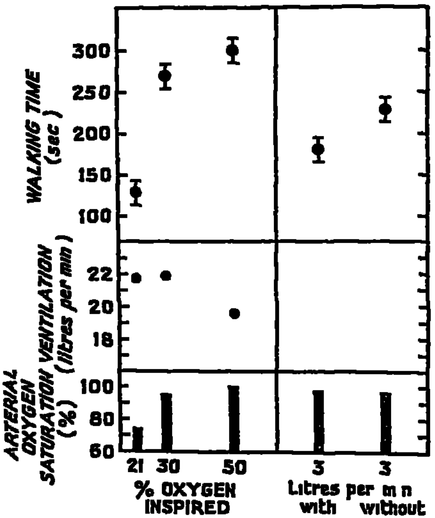

Fig 6—Effect of oxygen on walking time (cases 8, 12, and 26)

THE PHYSIOLOGICAL ACTIVITY OF TETRAIODOTHYROACETIC ACID

A W G GOOLDEN
M B Lond., D M R T

From the M R C Radiotherapeutic Research Unit, Hammersmith Hospital, London

THE acetic acid analogues of thyroxine and triiodothyronine differ from the circulating thyroid hormones in that the alanine side chain is replaced by acetic acid. The synthesis of tetraiodothyroacetic acid (tetrac) was described by Harington and Pitt-Rivers (1952). Pitt-Rivers (1953) compared the activity of tetrac and triac (triiodothyroacetic acid) in the prevention of thiouracil induced goitres in rats and found that both possessed about a tenth of the activity of L-triiodothyronine. Thibault and Pitt-Rivers (1955) found that the acetic acid analogues of both thyroxine and triiodothyronine were effective in raising the oxygen consumption of rat-kidney slices in vitro without a preincubation period, and that a single dose of tetrac raised the basal metabolic rate (B M R) of thyroidectomised rats within two hours, the effect wearing off after four hours. Lerman and Pitt Rivers (1955) described the effect in myxœdema of triac given daily by intravenous injection. Clinical improvement was accompanied by reduction in weight and plasma-cholesterol levels but no significant change in B M R. Trotter (1955) investigated the effect of triac in myxœdema and observed a clinical remission, with return of the B M R and plasma-cholesterol to normal values on a daily oral dose of 6 mg.

It was therefore of interest to determine the potency of tetrac in myxœdema, with particular emphasis on its effect on the plasma cholesterol level. A patient with primary untreated myxœdema was selected as a suitable subject for a therapeutic trial. A euthyroid volunteer was given tetrac in about the same dosage as the patient.

Methods

Both the patient and the control were given tetrac orally as an aqueous solution or in a capsule (figs 1 and 2). The solution was prepared by dissolving tetrac in sodium hydroxide (375 mg per ml of N NaOH), water being added to a final concentration of 4 mg per 30 ml. The solution was kept refrigerated. The 2 mg gelatin capsules were made up with a carbohydrate base. The B M R was measured with a Benedict-Roth apparatus, the results being expressed as a percentage of average normal values according to Robertson and Reid (1952) standards. Serum cholesterol was estimated by a modification of the method of Zlatkis et al (1953). The therapeutic effect in myxœdema was assessed by clinical observation, the daily weight record, the plasma cholesterol level, and the B M R.

Case-report

A woman, aged 62, was admitted to hospital, after a street accident, with mild concussion and fractures of both forearms. After a month in hospital she was discharged to a convalescent home. During convalescence it was noted that she was myxœdematous, and she was admitted to hospital for investigation and treatment. She gave a history of rheumatic fever at the age of 19 and had been admitted to hospital in 1948 with mild congestive failure, which responded to the usual measures. Aortic stenosis and incompetence due to rheumatic carditis were then diagnosed. After the accident she developed intolerance of cold, lethargy, postural vertigo, constipation, dryness of the skin, muscular cramps, impairment of memory, and inability to concentrate. Her daughter noticed an alteration in her voice and mental retardation. She may have been hypothyroid for some time but it appeared that her condition had deteriorated considerably since the accident.

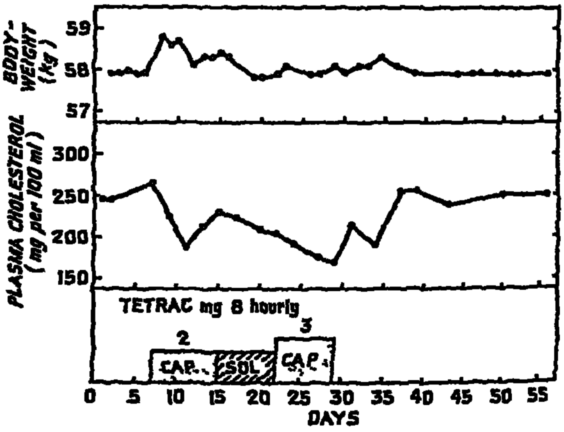

Fig 2—Effect of tetrac on weight and plasma cholesterol level in a euthyroid subject.

On admission she was lethargic and had a pale waxy complexion, thin hair, obvious puffiness of the eyelids, a deep voice, and dry scaly skin. Her thyroid gland was impalpable. There was evidence of aortic stenosis and incompetence but no sign of congestive failure except slight œdema of the ankles.

Investigations.—Chest radiography showed no cardiac enlargement. The initial B M R was −17%. The serum cholesterol level was 510 mg per 100 ml. Electrocardiography showed ischæmic changes but no evidence of myxœdema. Radio-iodine studies of thyroid function showed no appreciable thyroid uptake at 48 hours, 90% of the dose being excreted in the first 48 hours. No protein-bound radio-iodine was detected in the plasma. Serum electrolytes were within normal limits. The urinary excretion of 17-ketosteroids was 17 mg per 24 hours. The amount of follicle-stimulating hormone was greater than 48 mouse-units in 48 hours.

Response to Treatment.—Treatment with tetrac was started in a dosage of 1 mg 8-hourly (fig 1). No appreciable change was detected after 48 hours, when the dose was increased to 2 mg 8-hourly. After 2-3 days on the larger dosage there was obvious improvement, which was maintained for 2 weeks, by which

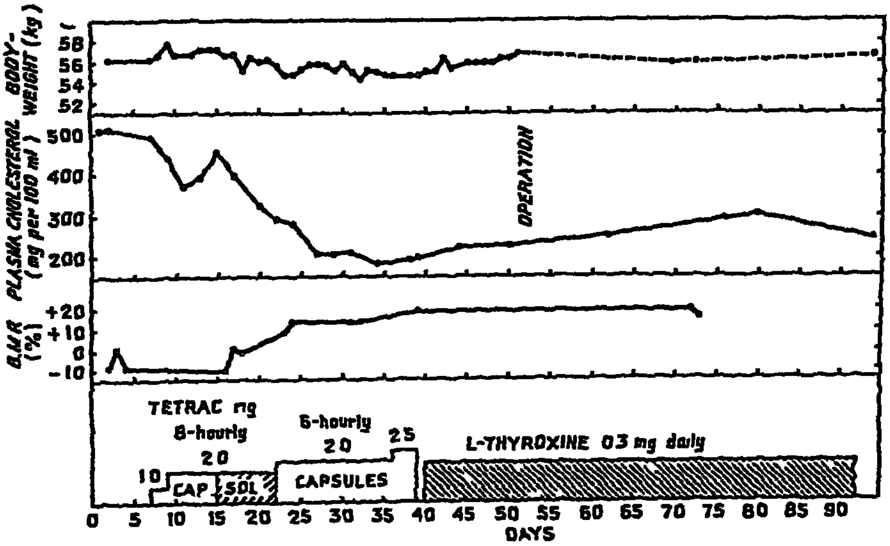

Fig 1—Effect of tetrac on weight, plasma-cholesterol level, and B M R in myxœdema

Selection of Patients

Since 1951 records have been kept by the joint consultative clinic of the Brompton Hospital and the Royal Marsden Hospital of all patients with a bronchial carcinoma attending the two hospitals, whether or not they were treated. The initial selection of patients for radiotherapy, once surgical treatment had been excluded, was made by the physicians and surgeons of the hospitals. The selected patients were, with few exceptions, referred to the clinic, where the final decision on treatment was made. Selection has therefore not been according to a single uniform policy. Radiotherapy was usually advised to alleviate symptoms rather than to prolong life. But many factors that cannot satisfactorily be recorded influence a decision on treatment, and some patients with few or no symptoms were treated, whereas others with symptoms were not. Although it is inevitable that the group of treated patients should contain fewer in a less advanced stage of the disease than the untreated group, the methods of selection at these hospitals have perhaps tended to reduce the difference between the groups.

Three-quarters of the treated patients in the present investigation were treated at the Royal Marsden Hospital. The length of treatment and the dose of irradiation were largely governed by the patient's general condition and the symptomatic response. It seems likely that in the whole series the more robust tended to get larger doses of irradiation.

Construction of Groups

The patients were selected from the 996 with bronchial carcinoma seen at the two hospitals in 1951–53, 221 of these were treated surgically, 321 were treated by radiotherapy, and 454 received no treatment likely materially to prolong life.

Exclusions

Patients with extrathoracic metastases at the time of diagnosis live for shorter periods than those without. Since so few such patients were treated by radiotherapy, their inclusion in the series would, of course, heavily prejudice the untreated groups. All with evidence of extrathoracic metastases at the time their treatment was decided have therefore been excluded. A patient must live for at least a month after first attending hospital if he is to receive a dose of radiotherapy sufficiently large materially to alter the course of the disease, for it is unlikely that the necessary investigations and arrangements can be made and the treatment given in a shorter time than this. To include among the untreated patients those who died within a month would bias the group, and these also have been excluded.

The groups for comparison were therefore taken from those patients without evidence of extrathoracic metastases when the treatment was decided, who lived for at least a month after first attending hospital, and in whom the time of the first appearance of symptoms was known. 213 patients treated by radiotherapy with an estimated dose delivered at the site of the primary tumour greater than 1000r fulfilled these requirements, as did 251 who received neither surgical treatment nor radiotherapy.

The after-history of 9 of these 464 is unknown. The remaining 455 were followed for two years from first attending hospital or until earlier death. To simplify the comparisons the few incompletely followed up have been excluded. This is thought to be justified because including them as dead at the time they were last heard of does in fact alter the survival experience of the groups very little, and the conclusions drawn from the comparisons are unchanged. There are therefore 207 treated by radiotherapy to be compared with 248 untreated.

TABLE I—THE TREATED AND UNTREATED GROUPS

—	Number of patients		
	No mediastinal metastases	Mediastinal metastases	Total
1000–3900r	49	65	114
Untreated	148	100	248
4000r or more	54	39	93
Untreated *	126	89	215

* 33 of the 248 untreated patients died within 2 months of first attending hospital, they have been excluded from the untreated group for comparison with treated patients having 4000r or more.

To receive a tumour dose of more than 4000r the patients must be under treatment for about four to six weeks. No patient who dies within two months of coming to hospital is likely, therefore, to have been able to receive such a dose of irradiation. 33 of the 248 untreated patients died within this period, 215 living for more than two months. The survival of the patients who received 4000r or more has therefore been compared with the survival of these 215.

Subgroups

The 207 patients in the radiotherapy group have been divided into two subgroups. 114 patients who received an estimated tumour dose of 1000–3900r, and 93 patients who received a dose of 4000r or more.

One group of patients might live longer than another because it contains fewer with regional node metastases and not because the treatment is different. The groups were therefore further divided into those with and those without evidence of mediastinal metastases at the time of diagnosis.

There are therefore four pairs of treated and untreated groups to be compared (table I).

Comparison of Groups

The groups were compared as regards the known distribution of histological types, the ages of the patients, and the durations of illness before diagnosis.

Only small and clearly unimportant differences were found in the distribution of histological types of tumour and ages of the patients between the groups receiving 1000–3900r and the corresponding untreated groups. The survival of a group containing a large proportion of patients with a duration of symptoms of about six months before diagnosis is likely to be shorter than that of a group with fewer such patients (Bignall 1955).

There were only slight and unimportant differences in the distribution of the durations of symptoms, and the proportions with symptoms for three to eleven months were almost identical in treated and untreated. In the untreated group there were, however, more in whom the diagnosis might be doubted. For instance, there was neither histological, thoracotomy, or necropsy confirmation of cancer nor knowledge of metastases throughout the illness in 66 (45%) of the untreated compared with only 11 (22%) of the corresponding radiotherapy groups. 2 of the 66 and 1 of the 11 patients were still alive when last heard of.

A comparison of those treated with 4000r or more with the corresponding untreated groups also shows only minor differences. There was neither histological thoracotomy, or necropsy confirmation nor knowledge of metastases in 54 (43%) of the untreated and 11 (20%) of the treated. 2 of the 54 and 3 of the 11 patients were still alive when last heard of.

In these selected groups there were therefore no important differences in the distribution of factors known to influence survival. In spite of this the untreated

CARDIAC PAIN FROM ŒSOPHAGEAL LESIONS

GEOFFREY BOURNE
M D Lond , F R C P
PHYSICIAN IN CHARGE OF THE CARDIOLOGICAL DEPARTMENT,
ST BARTHOLOMEW'S HOSPITAL, LONDON

In his St Cyres lecture Dr William Evans drew attention to the association between œsophageal contraction of an abnormal type and cardiac pain (Evans 1952) He found that pain suggesting coronary disease was present in 332 patients, all of whom had a normal electrocardiogram They were contrasted with an adequate control series He found that in some cases the pain could mimic that of angina of effort and in others that of myocardial infarction Two of his points, particularly worthy of clinical comment, were

(1) The frequency with which such patients summoned medical aid, and the corresponding frequency of the diagnosis of coronary thrombosis, for which morphine was given

(2) That in 83 cases there were long intervals of freedom from pain—in 34 cases lasting up to two years, and in 49 for more than two years

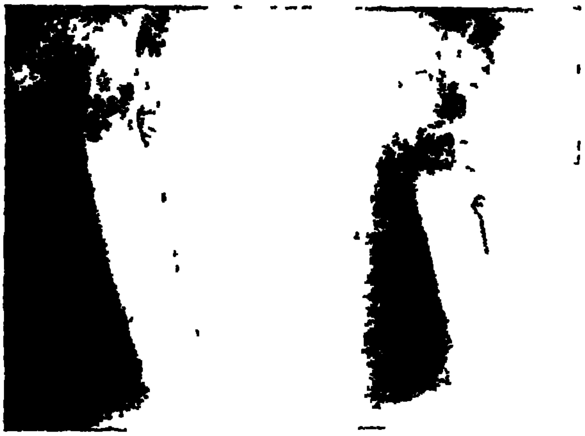

Fig 1—Case 1 diverticulum in middle third of œsophagus

Other observers have described cases in which pain suggesting coronary disease was present, the apparent cause being an abnormality of the œsophagus

Moersch and Camp (1934) found pain characteristic of angina pectoris in 2 patients with œsophageal spasm

Wolferth and Edeiken (1942) believed that many of the seizures thought to be due to angina pectoris were really caused by œsophageal spasm

Harrison (1945) reported 35 cases of œsophageal disease in which the pain resembled that of coronary disease, but in these patients he did not notice a relation between physical exercise and pain

Many other observers have stated that hiatus hernia can produce chest pain similar to that of coronary disease (Jackson and Jackson 1936, Jones 1941, Jones and Chapman 1942 Herman and Singer 1946)

The following is an account of two patients with organic œsophageal abnormalities who suffered from pain In one the pain resembled that of myocardial infarction, in the other it resembled angina of effort

Case-reports

Case 1 —A man aged 54 was admitted to St Bartholomew's Hospital after having a sudden attack of pain in the chest at the level of the upper part of the sternum whence it radiated down the left arm and up into the neck

On admission he was given morphine which relieved the pain He was not shocked His blood pressure was 120 80 mm Hg There was no evidence of increased venous pressure in the neck The heart sounds were normal and nothing abnormal was found in the abdominal organs, limbs, and nervous system

Treatment and Progress —Later in the day he had another exactly similar, attack, and two days later he had several more All were relieved by morphine His white cell count three days after the first attack was 5500 per c mm and erythrocyte sedimentation rate (E S R) 25 mm in the first hour (Westergren) The electrocardiogram was normal except for slight changes in the Q R S in lead VL only but such changes were thought to be possibly within normal postural limits He was discharged and returned to his work, and he remained perfectly well for two years

Readmission —He was then admitted as an emergency case, having again developed severe gripping retrosternal pain radiating to the left side of the thorax He was perspiring nauseated, and shocked Again no noteworthy abnormality was found in the heart or elsewhere The blood pressure was 110/95 The E S R was 16 mm in one hour and remained raised for two weeks

Treatment and Course —During this second admission he had seven further attacks in eight days, all of them requiring relief with amidone They lasted an hour or more—considerably longer than the average attack of anginal pain The electrocardiogram still remained within normal limits except for the very minor changes previously noted in lead VL it showed no evidence of myocardial infarction in the standard leads, the unipolar limb leads, or the unipolar precordial leads V_1, V_3, V_5, V_7

Diagnosis —Although on his first admission the diagnosis had been coronary thrombosis, suspicion was aroused during the second admission by the normal electrocardiogram and by the normal size and shape of the heart—which was, indeed small for his physique The transverse diameters of the heart and thorax respectively on the 6 foot X ray film were 10 5 cm and 25 5 cm

In view of these facts, and because it had been noticed that from time to time he swallowed air, the œsophagus became suspect On radiography a diverticulum of its middle third was found (fig 1) The stomach and duodenum were normal

The family history and the past history contained no point which appeared to be of importance

Case 2 —A man, aged 67, had for three or four years suffered from pain in the chest, radiating to both sides but not to the arms or to the neck It was induced by hurrying and by climbing hills or stairs and it was not associated with shortness of breath It lasted two or three minutes and was generally more severe in the morning Clinically it was strongly suggestive of typical angina of effort due to myocardial ischæmia from coronary disease

On examination his heart rate was 86, the rhythm being regular, and his blood pressure was 184/100 The heart lungs, and abdominal organs were clinically normal Radiologically the heart was small (10 4 cm in diameter) and vertical, the lung fields suggested emphysema The electrocardiogram, after considerable exercise, remained normal in the standard leads, the unipolar limb leads, and the unipolar precordial leads V_1, V_3, V_5, V_7

On radiography the œsophagus showed a sliding hiatus hernia (fig 2) but with very little gastro œsophageal reflux

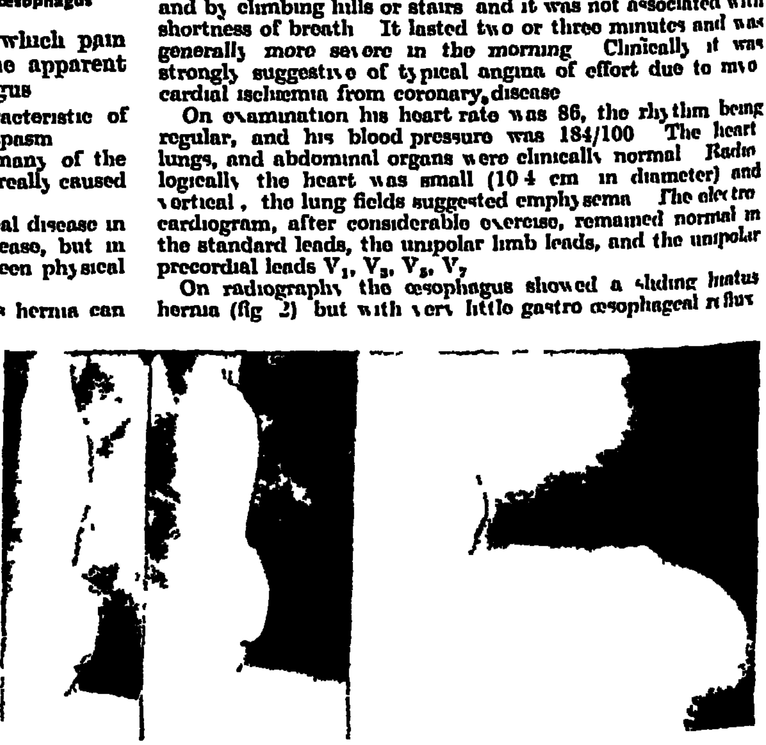

Fig 2—Case 2 hiatus hernia

futile to make direct comparisons Bloch and Bogardus (1940), on the other hand treated 88 patients and found that duration of life from the first symptom was the same as in untreated patients, and Graham et al (1935) stated that radiotherapy does not prolong life

Craver (1940) recorded longer survival in those treated with the larger dose of irradiation Brown (1952) found that 6 of 39 patients treated with 2000–3000r survived nine months, compared with 39 of 92 treated with 4000–5000r, and concluded that the survival-rate was definitely improved when doses of over 4000r were given But Adelman (1952), who also noted increasing mean survival with increasing dose of irradiation, pointed out that patients receiving high doses are generally in a less advanced stage of cancer and would be expected to live longer without any treatment

There is, it appears, no conclusive evidence that radiotherapy prolongs life or that large doses have a greater effect on survival than small doses

The differences observed in the present investigation may have been due to chance sampling variations differences in the composition of the groups, or the effect of radiotherapy The treated and untreated groups were undoubtedly dissimilar In spite of the attempt to select groups as near as possible alike, the untreated groups probably contained more patients in an advanced stage of the disease For instance, in the case of those without metastases who received 4000r or more, only 6 (11%) had been judged to be in too poor general condition to withstand lung resection, but in the untreated group with which they were compared there were 34 (27%) such patients However, if these more ill patients are excluded from both groups, the differences in survival are little changed, 38% of the 48 remaining in the treated group lived a year and 17% two years, compared with 27% and 6% of the 92 untreated

The differences between treated and untreated might have been partly due to there being more patients in the untreated group likely to die in a short time There would then be more untreated patients dying within six months of first attending hospital This was indeed found But there was a large excess, and it is doubtful whether it was entirely due to selection For instance, in the group in which the difference was greatest—those without metastases treated with 4000r or more—as much as 30% of the 126 untreated patients must be assumed to have been too advanced for inclusion in the group to bring the pattern of survival close to that of the treated patients On the other hand, such an explanation of the differences is certainly possible, because, if 38 (30%) are excluded from the number who died in the first six months, the proportions of the remaining 88 dying in the four six-month periods up to two years would be 24%, 47%, 19%, and 7%—proportions remarkably similar to those observed in the corresponding treated patients 22%, 43%, 15%, and 4%

The observed differences between treated and untreated groups could have been due entirely to the dissimilarity of the groups and random sampling variations, without radiotherapy having had any effect, beneficial or deleterious, but it seems improbable The differences between treated and untreated in the patterns of survival are greater in those without mediastinal metastases than in those with them In the groups treated with small doses of irradiation the patterns were indeed almost identical in those with metastases, although there were noticeable differences in those without But there seems to be no reason to believe that more patients with advanced disease were selected for treatment from those with metastases than from those without Selection probably operated to about the same extent in both groups Some of the differences observed might therefore have been due to the treatment, and it seems reasonable to suppose that, if the course of the disease is changed at all, it will be altered least in patients who already have intrathoracic metastases

There seems to be suggestive but by no means conclusive evidence that radiotherapy prolonged the life of some patients in this series, but, even if life were prolonged, it is highly unlikely that the larger doses of radiotherapy given to the most favourable patients—those without manifest mediastinal metastases—caused an increase of as much as 10% in the proportion surviving a year after first attending hospital or 5% in those living for two years

This report is not concerned with whether a probable increase of the order suggested justifies greater or less use of radiotherapy in bronchial carcinoma, nor with the effects of treatment on the patient's symptoms or his peace of mind

Summary

The course of the disease has been studied in 455 patients with bronchial carcinoma 207 were treated by radiotherapy, 114 receiving an estimated tumour dose of 1000–3900r and 93 4000r or more Their survival is compared with that of 248 who received no treatment likely to prolong life

The groups were selected to be as far as possible alike in the factors known to influence survival No patient was known to have extrathoracic metastases when the decision on treatment was made

The greatest difference between treated and untreated in the duration of life from first attending hospital was found in those without mediastinal metastases treated with 4000r or more 35% lived a year and 15% two years, compared with 24% and 6% of the untreated

In the patients with mediastinal metastases the differences were less, and the pattern of survival of those treated with 1000–3900r was almost identical with that of the corresponding untreated group

There is suggestive evidence that the differences were not due entirely to selection and random-sampling variations but were contributed to by the radiotherapy

In this series of patients it is unlikely that radiotherapy caused an increase of as much as 10% in the proportion surviving a year after diagnosis or 5% in those living two years, even in the most favourable cases treated with higher doses

I am indebted to the medical committees of the Brompton Hospital and the Royal Marsden Hospital for permission to publish this report which records part of the work of the joint consultative clinic of the two hospitals The keeping of records and tracing of patients was largely done by Mrs I Appleby of the secretarial staff of the Institute of Diseases of the Chest I am grateful to Mr P M Payne statistician to the Royal Marsden Hospital for his advice

easy access to a clinic should refer to one of the original papers, which are listed in the book or can be found from Dr Fraser's paper This caution applies particularly in one or two instances where Dr Reed has used a method of arriving at the risks which is of doubtful validity, and has led him to quote too high a risk—for example, for harelip In this instance a better estimate is given in the appendix But in general the book is stimulating and should well fulfil its purpose of indicating when advice on genetic risks can be helpful to parents

Medical History of the Second World War

Royal Air Force Medical Services Vol II Commands Edited by Squadron Leader S C Rexford-Welch, M R C S R A F H M Stationery Office 1955 Pp 703 75s

THIS volume describes clearly, and at times dramatically, how wide was the range of duty which fell to the medical branch of the R A F The estimation of flying stress and its relation to courage, the choice of rations for crews on long flights or in escape dinghies, the supervision of the early parachute troops, the industrial hazards of some of the maintenance work—these were some of the problems thrust on doctors as an addition to routine public health and care of the sick The story is extremely well set out, with detail enough to present a tale worth reading, and it does not shirk the difficult matter of the relationship of the medical officer with the executive officer

Planning had to be, and was, adjusted to unforeseen changes in the pattern of warfare The accounts of the expeditions to the Azores and to Iceland are both fully elaborated both contain lessons of general application to any military exploit, whatever the weapons used Though the book is long, it is hard to see how it could have been made much shorter without losing its value as a textbook and guide for doctors who choose or are called on to undertake medical duties in a fighting service

The Cornea

CHARLES I THOMAS, M D, associate clinical professor of ophthalmology, department of surgery, Western Reserve University School of Medicine Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1955 Pp 1318 £10 16s

MUCH industry ingenuity and thought have gone into this comprehensive book It is an admirable achievement to correlate, as far as is at present possible, such a large mass of scientific and clinical data There must be little in the enormous literature on the subject of the cornea which has escaped attention

For the scientist there is particular interest in the chapters dealing with embryology, anatomy, physiology, and pathology of the cornea, and for the clinician there is valuable instruction in the chapters on diseases of the cornea The difficult subject of corneal dystrophies is especially well treated

The author has not made clear Paufique's technique for dealing with a broad synechia before a corneal transplant The reader is left with the impression that this is done at the same time as the keratoplasty and by using an 8-9 mm trephine, which is not the case Not all surgeons would agree with the use of ointment in the conjunctival sac at the end of a penetrating corneal transplant operation and many surgeons would prepare the donor material before the recipient site Most of the illustrations photographs artist's drawings, and diagrams are excellent, but a few photographs are indistinct

This is a book to which all ophthalmologists and those interested in the basic sciences of ophthalmology will wish to refer

Heaven and Hell

ALDOUS HUXLEY London Chatto & Windus 1956 Pp 88 7s 6d

TWO years ago in *The Doors of Perception*, Aldous Huxley described his subjective experiences after taking a dose of mescaline He was an experimental subject who was exceptionally well qualified to communicate the nuances of this peculiar intoxication, which is of medical interest because of its relationship with other forms of hallucinosis He was, if anything, too eloquent His insistence on the transcendent qualities of his perceptions became in the end reminiscent of a neurotic patient's exaggeration of his symptoms Finally, it seemed that it was not the effects of mescaline but rather the exquisite sensibilities of the author that were being demonstrated to the reader

In this sequel to that essay, he offers his reflections upon the psychological implications of the mescaline experience It is soon made plain that his temperament is antipathetic to any scientific assessment of the phenomena Instead, speculation and metaphor are interwoven with fragments of physiological data in order to construct a plausible fiction, in a manner reminiscent of D H Lawrence's *Fantasia of the Unconscious* Systematic observation and verification are alien to this approach, and yet he does throw out perceptive insights such as "Colour turns out to be a kind of touchstone of reality"

As a contribution to the phenomenological study of the *fantastica*, this essay must itself be regarded as a potent stimulant—to be taken with a pinch of nicotinic acid

Progress in Clinical Obstetrics and Gynæcology

T L T LEWIS F R C S, M R C O G, obstetric surgeon, Guy's Hospital, surgeon, Queen Charlotte's Maternity Hospital London J & A Churchill 1956 Pp 594 55s

WRITTEN for the specialist who has not been able to keep up with the vast literature, and for the postgraduate student who is reading for the M R C O G examination, this book tackles many difficult and debatable matters

For example, there are chapters on congenital malformation and rubella, postmaturity, postpartum hæmorrhage and the management of the third stage, and of afibrinogenæmia and amniotic fluid embolism In the gynæcological section Mr Lewis deals among other things, with stress incontinence, venous thrombosis and pulmonary embolism, cytology in uterine cancer, and pelvic exenteration The subjects have been well chosen, and each is thoroughly discussed

The author says he has "tried to present the evidence without prejudice before drawing conclusions," and he has succeeded admirably His book is well written and contains much wisdom

Final Contributions to the Problems and Methods of Psycho-analysis

SANDOR FERENCZI M D Editor MICHAEL BALINT, M D, PH D, M SC Translators ERIC MOSBACHER and others London Hogarth Press and the Institute of Psycho Analysis 1955 Pp 447 30s

PSYCHO-ANALYSTS are tireless in their bibliographical labours they gather, and if necessary translate, the whole corpus of published writings by the notable pioneers This is the third volume of Ferenczi's literary remains There is a hint in the preface that his scientific diary and the correspondence between him and Freud over a period of 25 years are also to be issued in due course The papers here presented include those written between 1926 and his death in 1933, and various notes, fragments and minor articles The most interesting are those written after 1927 in which he put forward his heterodox proposals about relaxation and indulgence (*Nachgebigkeit*) in therapeutic technique There are throughout the volume and especially in the fragmentary notes, intimations of Ferenczi's intuitive, fertile and sometimes startling approach to the problems that he saw in psycho analysis The book also contains a complete bibliography of those of his papers that have been translated into English and an elaborate index for which the explanatory notes alone take up a page

---

Bacterial Anatomy (London Cambridge University Press 1956 Pp 360 30s)—The fifteen papers which were discussed at the sixth symposium of the Society for Microbiology were published shortly before the meeting last April, so that members might consider them in advance Under the editorship of Prof E T C Spooner and Dr B A D Stocker and supplemented by some excellent plates they make a handsome volume which will also be an informative consolation prize to non attenders

Discussion

We fully recognise that the number of cases treated in this way is very small and that therefore the figures are not of statistical value but they suggest that the results of radiotherapy may eventually bear comparison with those of surgery. One must also bear in mind that with improved apparatus and greater skill, the results of radiotherapy may reasonably be expected to improve.

In 4 cases reported by Brooks et al. (1951), which were treated by X rays alone and came to necropsy, there was no macroscopical evidence of the original growth in the lung. This suggests that the growth, in some cases, can be adequately treated by radiotherapy provided there is no secondary deposit elsewhere.

There are three other factors which may influence the results of treatment.

(1) There is no immediate mortality after radiotherapy whereas the operative mortality-rate in the series of Bignall and Moon (1955) was about 10%.

(2) Clinical evidence of cerebral metastases seems to be more common after surgical intervention than after radiotherapy. 10 of 25 patients who died after surgery in a series described by Bignall (1955) showed clinical evidence of secondary cerebral deposits, whereas only 2 of 18 patients had cerebral deposits after treatment by radiotherapy.

(3) 24 of 81 cases thought to be operable were found at operation to be inoperable (Bignall 1955). This mistake may well have occurred in our own selection of cases; hence we also may have been including cases more advanced than was evident.

Conclusion

Although this is an extremely small series, the results suggest that radiotherapy in selected cases may be an adequate alternative to surgery.

We are indebted to Dr K. F. W. Hinson, pathologist at the London Chest Hospital, for examining the biopsy sections and sputum for carcinoma cells; Mr. P. Armitage, honorary statistician to the Institute of Diseases of the Chest, for his advice with regard to our figures and for estimating the standard error; and Dr. L. Capel for help in preparing the tables.

Appendix

A more detailed analysis of these results is shown in table I and compared with the results of Bignall and Moon (1955) in table II. The survival-rate is calculated by the life-table method, which enables those patients followed up over a shorter period to be assessed. Bignall and Moon made similar calculations for their larger series. It will be seen that, in the series treated by radiotherapy, a two-year survival-rate is 55·6%. From statistical considerations the standard error is estimated at 9·3%; hence the true figure lies between 37% and 74% with a 95% chance that this is correct.

The two-year survival rate for surgically treated cases is 45%. At least 10% of the patients treated surgically died within two months of operation and were excluded from the series. This would reduce the two-year survival rate for surgically treated cases to 42%. This figure lies well within the range of our findings. If a reasonable allowance is made of a standard error of 2½% in the surgical list, it may be calculated that the probability of getting by chance so big a difference in the two-year survival rate (55·6% for radiotherapy and 42% for surgical resection) is between 0·1 and 0·2.

TABLE I—SURVIVAL RATES OF PATIENTS AT 3 MONTH INTERVALS AFTER RADIOTHERAPY

Interval (completed mos. from bronchoscopy)	At risk at start of interval	Survival-rate (%)
0–2	33	100·00
3–5	32	100·00
6–8	30	96·83
9–11	29	96·83
12–14	23	76·80
15–17	22	73·46
18–20	20	70·04
21–23	18	63·04
24–26	14	55·63
27–29	10	43·27
30–32	7	38·46
33–35	7	38·46
36–38	6	38·46
39–41	5	32·05
42–44	5	32·05
45–47	5	32·05
48–62	4	32·05

TABLE II—SURVIVAL-RATES OF PATIENTS LIVING LONGER THAN 2 MOS. AFTER OPERATION *

Interval (completed mos. from operation)	At risk at start of interval	Survival rate (%)
0–2	453	94
3–5	423	82
6–8	367	73
9–11	326	63
12–14	282·5	58
15–17	259·5	54
18–20	237	51

OPERATIONS for portal hypertension require careful planning. The patients need to be fixed on the operating-table in such a position that it is possible to alter the tactical approach in the light of discoveries made on exploration. We had to be prepared, for example, to change from a right lateral approach to the portal vein (through an oblique incision extending from the umbilicus

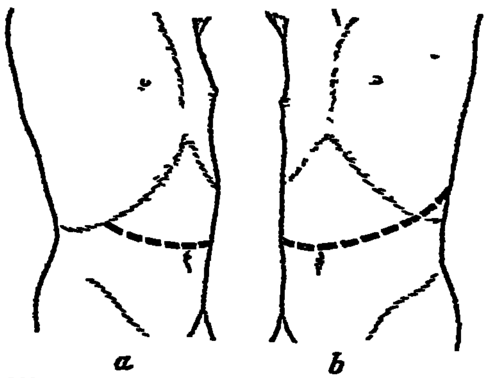

Fig. 1—Oblique abdominal incision (a) for exploration of portal vein before intended portacaval anastomosis. Vein was found unsuitable; so incision was extended (b) to left and up through bed of left 10th rib for lienorenal anastomosis.

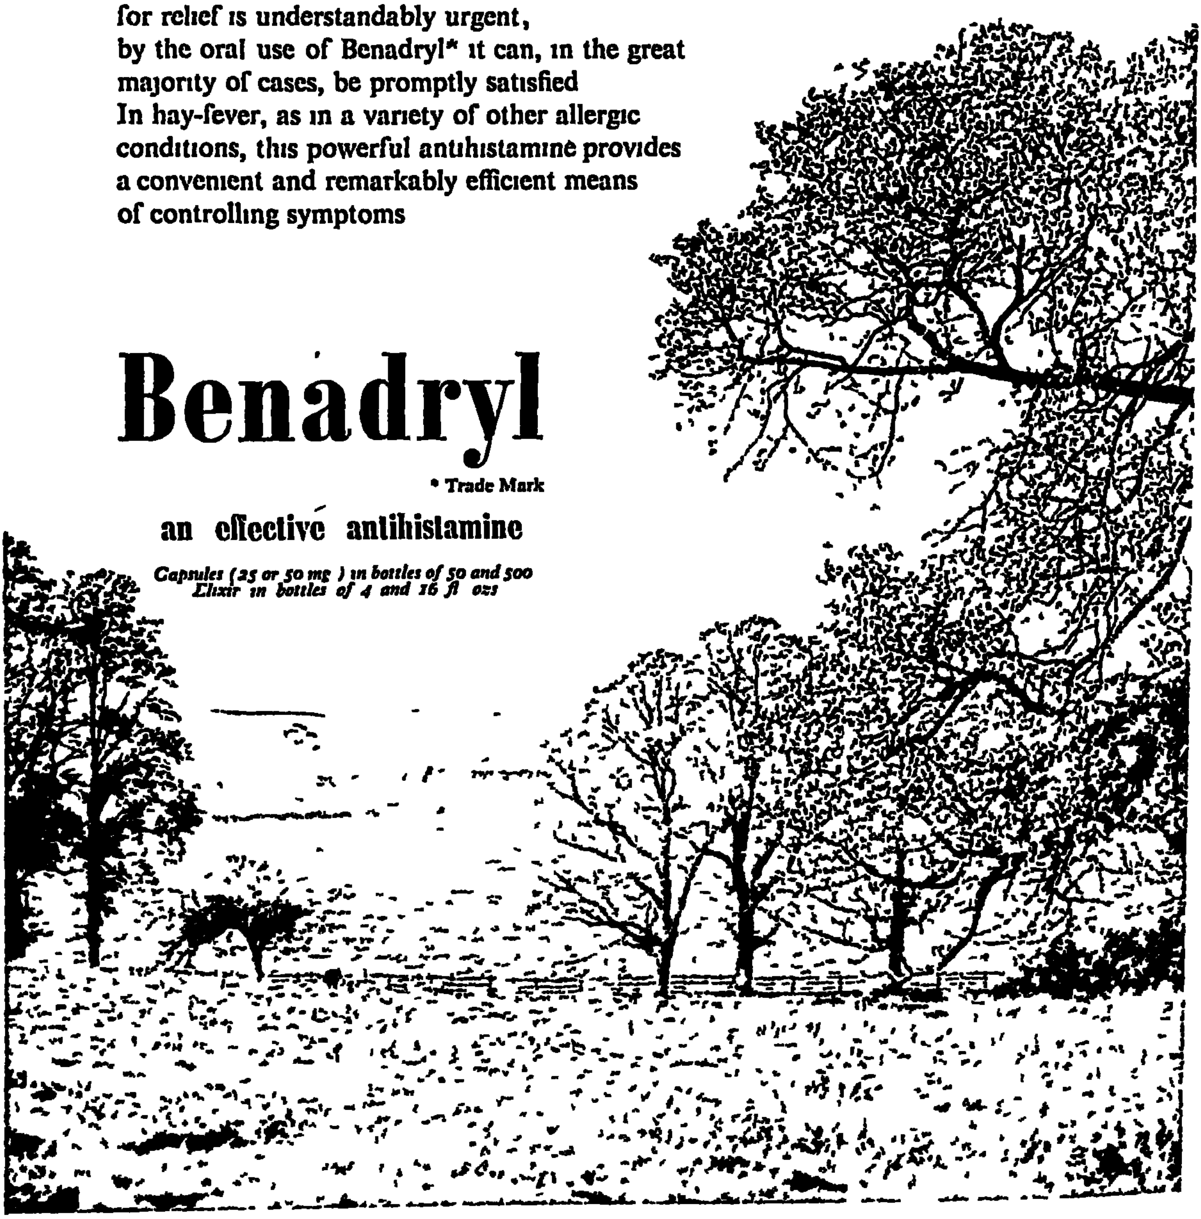
Nothing so active is as that which least seems so

Francis Thompson

A peaceful countryside scene but an active source of intense discomfort for all those susceptible to hay-fever, for now is the time of the year when invisible air-borne pollens begin to take their toll Incapacitated by continual weeping, sneezing and nasal congestion, the hay-fever patient's desire for relief is understandably urgent, by the oral use of Benadryl* it can, in the great majority of cases, be promptly satisfied In hay-fever, as in a variety of other allergic conditions, this powerful antihistamine provides a convenient and remarkably efficient means of controlling symptoms



Benadryl

* Trade Mark

an effective antihistamine

Capsules (25 or 50 mg) in bottles of 50 and 500
Elixir in bottles of 4 and 16 fl ozs

PARKE, DAVIS & COMPANY, LIMITED (Inc U S A) HOUNSLOW, MIDDLESEX Tel Houn[illegible] had a profound effect on the outcome of the disease in 2 cases

Material

50 "new" cases of pernicious anæmia attending hospital were reviewed and their weight losses (if any) were measured After treatment the patients were weighed regularly for at least eighteen months

Of our 50 cases it was found that 14 (28%) admitted to losing at least 1 st in weight in the months preceding admission The largest weight loss was 3 st 4 lb, and it is interesting that 4 (28%) of these 14 cases were first diagnosed as carcinoma of the stomach

2 other cases were similarly diagnosed because of weight loss which was described as "gross" in 1 case and justifying the label "cachectic" in the other The amount of weight lost was not recorded in the notes in these cases, so they are not included in the above 14

Anorexia was commonly associated with weight loss and 12 of the 16 patients who lost weight had this symptom The anorexia was often accompanied by nausea, upper abdominal pain, and sometimes diarrhœa, and it seems that cases with weight loss commonly have alimentary symptoms Following our cases after treatment we were able to confirm that weight loss seems to be regained fully after vitamin-B_{12} therapy, often rapidly but sometimes not for twelve to eighteen months

An example of gross weight loss in pernicious anæmia and of a resulting mistaken diagnosis is given below.

Case 1—A man, aged 65, was seen as an outpatient complaining of severe anorexia and gross loss of weight—3 st in four months This was accompanied by central epigastric pain and vomiting There was clinical anæmia, wasting, and slight jaundice but no other abnormal physical signs Because of these signs the diagnosis on admission was malignant disease of the "alimentary tract or pancreas"

Investigations—Weight 13 st 12 lb Blood count Hb 5 6 g per 100 ml (38%) red cells 1,200,000 per c.mm mean corpuscular volume 133 c μ, mean corpuscular hæmoglobin concentration 35%, white cells normal Bone marrow biopsy extreme cellularity with megaloblastic erythropoiesis Barium meal normal. Fractional test meal histamine fast achlorhydria

Progress—After vitamin B_{12} therapy there was a reticulocytosis reaching 25% on the seventh day, with subsequent improvement in the hæmoglobin level Most dramatic of all was the rapid return of well being with a voracious appetite and a quite remarkable increase in weight He put on 1½ st in the fourteen days after the first injection, is now very well and symptomless with a normal blood count, and in six months has regained 2½ st of his lost weight

Though the severe weight loss in this case temporarily misled the clinician and caused the patient to have an unnecessary barium meal, the outcome was most gratifying

However, there are cases in which such a fortunate outcome is not obtained, and failure to recognise that weight loss is fairly common with pernicious anæmia may have disastrous results as in the following case

Case 2—A woman aged 67, was admitted with a history of pallor, shortness of breath anorexia, and considerable loss of flesh in the past year Four months before admission she had been seen by a specialist who because of the anorexia, slight icterus, cachexia, and hepatomegaly, diagnosed carcinomatosis from a gastric primary neoplasm. Unfortunately, because of her age and feebleness he did not investigate her further

On admission she was grossly anæmic and wasted There was slight icterus and some epigastric tenderness, but no other abnormality

Investigations—Hb 17% Red cells 630,000 per c mm, red cell diameter 8 4 μ Blood film showed pronounced anisocytosis and poikilocytosis

Course—Despite intensive treatment with intramuscular injections of liver extracts, as was usual at this time, and slow administration of a blood transfusion, she died three days after admission, without responding to treatment

Necropsy revealed the classical changes of pernicious anæmia in the bone marrow and gastric mucosa

Fortunately such errors in diagnosis are not common, but there is little doubt that this illness, if detected earlier, would not have been fatal The simulation of malignant disease was here so close as to lead to a confident diagnosis of carcinomatosis There is, therefore, a risk that patients with pernicious anæmia will be dismissed as having untreatable cancer, particularly when weight loss is severe

This danger, though small is much greater when pernicious anæmia develops in patients who have already been treated for malignant disease, because when loss of weight, pallor jaundice, and hepatomegaly develop, and they complain of anorexia and general ill health it is easy to assume that metastases have arisen from their original neoplasm Hence the symptoms and signs of pernicious anæmia may be mistaken for those of widespread neoplasia, particularly if the surgeon concerned is not used to recognising and treating pernicious anæmia The next case illustrates this danger

Case 3—A man, aged 77 was operated on in 1943 for a rectal neoplasm The growth was excised and a colostomy performed He remained well until 1952 when he began to complain of anorexia, loss of weight, and general debility The surgeon attending him noticed that he was anæmic and jaundiced and that his liver was palpable Carcinomatosis was diagnosed, so no investigations were done till a year later when he was admitted moribund

On admission he was obese, anæmic and slightly icteric The liver was firm smooth and enlarged three finger breadths below the right costal margin Apart from a normally functioning colostomy there were no other abnormal physical signs

Investigations—Hb 4 9 g per 100 ml (33%) Blood film showed pronounced macrocytosis, anisocytosis, and poikilocytosis Bone marrow biopsy changes of classical megaloblastic erythropoiesis

Course—Vitamin-B_{12} therapy induced a reticulocytosis of 10% but the patient contracted bronchopneumonia a week after the start of treatment and this, together with his anæmia, resulted in his death

Necropsy revealed the changes of pernicious anæmia There was no evidence of any recurrence of the rectal neoplasm

Discussion

In about a third of all cases of pernicious anæmia weight loss usually associated with anorexia, is an important feature This loss may be masked by (1) patients being stout despite their loss of flesh, and (2) elderly patients being uncertain of their usual weight

We have shown that in pernicious anæmia severe weight loss may result in a mistaken diagnosis and an occasional tragedy The simulation of malignant disease is in some cases very close and may be misleading

In dealing with patients who complain of loss of weight, pernicious anæmia should be remembered as a possible cause Usually severe weight loss in such cases is accompanied by correspondingly severe anæmia, but we have seen cases where weight loss of a stone or more has been present with a hæmoglobin of 70% or higher It is, therefore, important to examine blood-films and bone-marrow where weight loss has occurred Of course clinical evidence of anæmia accompanying weight loss and other alimentary symptoms may well be due to a malignant neoplasm of the alimentary tract, but it is always worth while fully investigating the anæmia before sending patients for radiographic studies of the alimentary tract When pernicious anæmia has been diagnosed and treatment instituted, the return of appetite, weight and well-being will usually dispel all thoughts of neoplasia

It has been shown that carcinoma of the stomach is commoner in patients with pernicious anæmia than in other members of the community (Videbæck and Mosbech 1954), and an incomplete response to vitamin-B_{12} and persistence of alimentary symptoms may occasionally lead to the discovery of a gastric neoplasm However, other nutrients, such as pyridoxine pantothenic acid, biotin, and folic acid whose full importance may not yet be apparent If we did not know that very small nutritional deficiencies (conditioned or otherwise) can have very great effects, and if we were quite sure that none of the current disorders of civilised man can possibly have a nutritional origin, we might be happier about the panel's implication that what is unproven can be (fairly) safely ignored Admittedly it reaches its conclusions after the proper hesitations —' the history of nutrition reveals many instances where the refinement or over-purification of food has led to ill-health and there is no reason to believe that this chapter of knowledge is closed '—but this does not lessen our doubts about the conclusions themselves When the panel says that a lowering of the extraction-rate from 80% to 70% *is very unlikely* to lead to any nutritional disturbance from lack of pyridoxine, pantothenic acid, biotin, and folic acid, and that there is no ascertainable difference between National flour and fortified flour which would *significantly* affect the health of the population " in any foreseeable circumstances," it is making guesses that embody risks, and these are risks that are going to be multiplied by 50 million Even in the more limited " present circumstance " to which the Minister of Agriculture confines his own statement,[2] bread is probably becoming perforce an increasingly prominent part of the diet of many people in this country, and their number may rapidly increase We share the view of the M R C conference that, though the new policy may not lead to an increase in recognisable illness, it carries a risk that can be avoided

As things stand there is every prospect of the nation returning to the familiar situation in which people receive what it suits the millers to give them

Thyroid Hormones and Coronary Disease

NOT long ago, coronary-artery disease was regarded as an inevitable accompaniment of the process of growing old, which there was no prospect of averting In recent years a remarkable change has come over our attitude to this condition, and many people now regard it as something which could be corrected if enough was known about its cause We have lately referred to some of the reasons for this change of attitude[3] If further investigation shows that high blood-cholesterol levels do in fact predispose to thrombosis with or without atheroma various means of avoiding excessive cholesteræmia may prove practicable One would be to lower the total fat content of the diet, or the proportion of different kinds of fats Another which has been proposed is the administration of sitosterol, a plant steroid which interferes with the absorption of cholesterol[4] though only when taken in inconveniently large quantities Another possible line of attack is hormonal It is well established that coronary artery disease is less prevalent in women than in men, particularly at the younger ages, and administration of œstrogens lowers the blood cholesterol[5] Similarly TURNER and STEINER[6] showed that thyroid extract lowered the blood cholesterol level of euthyroid subjects, though it also raised the basal metabolic rate (B M R) by an average of 20% GILDEA et al[7] made similar observations in patients with hypometabolism but no signs of myxœdema, again, a fall in blood-cholesterol was accompanied by a rise in B M R They noted, however, that larger doses of thyroid extract were needed to lower the blood cholesterol of euthyroid subjects than was the case in patients with myxœdema STRISOWER, GOFMAN and others[8] [9] have recently shown that large doses of thyroid extract given to schizophrenics lowered not only the total blood-cholesterol but also the lipoprotein fractions which they regard as particularly associated with atheroma The patients' B M R s were not measured, but they lost weight Thyroid extract clearly changes the blood-lipoprotein pattern in the right direction, but only at the expense of an increase in general metabolism This increased metabolism is a disadvantage, in that it is likely to make the patient uncomfortable, and it might also be dangerous in a person whose coronary arteries are already narrowed, for it must necessarily increase the work of the heart, and therefore the amount of blood which must be carried by the coronaries

The hormone secreted by the thyroid is thought to consist mainly of thyroxine, in addition, triiodothyronine is also either made by the gland or formed elsewhere from thyroxine These two substances are supposed to have similar physiological actions, though triiodothyronine is the more powerful Numerous synthetic variants of these two substances are also known, many of which are physiologically active in varying degrees It has been presumed that the difference in the physiological activity of these substances were purely quantitative But now it is suggested, in papers by Dr TROTTER and Dr GOOLDEN in this issue, that there may be qualitative differences between the various chemical versions of the thyroid hormone Just as changes in the chemical structure of the adrenal cortical hormones increase the relative effects on either glucose or mineral metabolism, so alterations in the thyroxine molecule may emphasise either the cholesterol depressing or the metabolic effects of the thyroid hormone As it happens, both Dr TROTTER and Dr GOOLDEN deal with the same modification of the molecule whereby the tyrosine side-chain is replaced by acetic acid Dr GOOLDEN'S substance is the acetic-acid analogue of thyroxine (tetrac), while Dr TROTTER'S is the acetic acid analogue of triiodothyronine (triac) Both substances originated in Mrs PITT RIVERS's laboratory at the National Institute for Medical Research where their physiological properties are being closely studied

It is evident that in their action in man the new compounds do not differ radically from their parent substances Both will relieve the symptoms of myxœdema, at the same time restoring B M R and blood cholesterol to normal The action of both substances is more rapid than that of thyroxine, though not necessarily more rapid than that of triiodothyronine The main point of interest is that both Dr TROTTER and Dr GOOLDEN suggest, though only tentatively that the acetic acid analogues may history could be obtained other than that of repeated hæmatemesis during the previous three months She died forty eight hours later after a hæmatemesis

Necropsy Findings—Of senile physique, wasted and slightly jaundiced Hæmorrhage from œsophageal varices, and much blood in stomach and intestines Œdema of lungs, brown atrophy of myocardium, ischæmic scarring of the kidneys Liver shrunken, with prominent regeneration nodules Spleen enlarged and firm Moderate ascites Length of small intestine 12 ft 6 in.

Histology—Chronic inflammation of the mucosa of the jejunum, with focal subacute inflammation The ileum and colon were normal The liver showed coarse fibrosis, with fatty degeneration of the residual cells and regeneration of bile ducts.

Case 5—A man, aged 52 complained of vomiting blood at intervals for a year He had always been regarded as an invalid and until the age of 20 had epileptic fits He had lost weight recently, fluid was present in his abdomen, his ankles were swollen, and his superficial abdominal veins were distended. He died after a severe hæmatemesis

Necropsy Findings—A thin, œdematous, and lightly jaundiced male with venules on nose and prominent abdominal veins Bilateral pleural effusions, each of about 2 pints, and severe pulmonary œdema Ascites of 4 pints Œsophageal varices present but not ruptured Hæmorrhage from multiple acute erosions of stomach and colon The liver weighed 90 oz and showed diffuse portal fibrosis, small regeneration nodules being more prominent in the left lobe than in the right The spleen showed changes due to portal obstruction and weighed 15 oz The small intestine measured 14 ft

Histology—Portal fibrosis of liver with regeneration of liver cells and bile ducts Section of intestine showed slight terminal inflammation of mucosa

Discussion

There is very little accurate information about the length of the small intestine, 18–23 ft being the usual estimate, but Underhill (1955) has found the following measurements (including the duodenum)

	No of cases	*Minimum ft*	*Average ft in*	*Maximum ft in*
Male	65	16	20 11	25 9
Female	35	11	19 5	23 6

There is still no guide to the normal range, and it would be interesting to know the causes of death of patients with a short intestine and whether any had hepatic fibrosis

There are four possible causes of a short small intestine (1) surgical interference (which can be excluded in the present cases), (2) intestinal disease or disease elsewhere, (3) hypoplasia, and (4) simple atrophy (for which there is no evidence)

It is theoretically possible that a severe inflammation of the mesentery and serosal surface of the intestine—e g, tuberculosis—in an adolescent might limit the normal growth of the intestine, and so might internal inflammation, but this would more likely cause local deformity and a disturbance of the jejunum/ileum ratio

Disease in other sites may also influence the intestine

A woman, aged 47, who died of bronchopneumonia, had a most severe angular deformity of the lower cervical spine and a remarkable kyphoscoliosis, the result of spinal tuberculosis during adolescence Her lungs were small her liver depressed, and her small intestine 13 ft. long The growth of her intestine was probably limited by the bodily distortions; In precisely the same way one malformation in utero may induce other malformations in surrounding organs (Raeburn 1951)

In the present cases, however, nothing suggested antecedent disease as a cause of intestinal hypoplasia

Hypoplasia remains, and in the complete absence of any local disease this, we suggest, is the true explanation Whether this is entirely a failure of natural postnatal growth, or whether congenital or familial factors operate, is unknown

In cases 1–4 the length of the small intestine was only 25–66% of the average and was well below the accepted minimal normal length of 14 ft Even thus deficiency would not necessarily produce any detectable impairment of intestinal absorption, but, if there were any severe intestinal disturbance, such a person would be liable to liver damage because of the small reserve of function

There is no direct evidence that a short intestine contributes to hepatic fibrosis, but it is not a common condition and is therefore worthy of record Of the 5 present cases 4 were in females Hepatic fibrosis is stated to be twice as common in males as in females (Anderson 1953)

We have since observed 2 other cases of portal fibrosis, both in males, 1 of them being associated with hæmochromatosis In these 2 cases and in numerous instances of "cardiac fibrosis" the intestine was of normal length

Summary

5 cases of short small intestine associated with hepatic fibrosis are described

Perhaps measurement of the alimentary tract should be a routine post-mortem procedure

In none of the present cases was there any history of acute hepatitis

EFFECT OF TRIIODOTHYROACETIC ACID ON BLOOD-CHOLESTEROL LEVELS

W R TROTTER
D M Oxfd, M R C P

From the Medical Unit, University College Hospital Medical School, London

THE acetic acid analogue of thyroxine was synthesised by Harington and Pitt-Rivers (1952) and the acetic-acid analogue of triiodothyronine by Pitt-Rivers (1953) These compounds were named tetraiodothyroacetic acid and triiodothyroacetic acid respectively, and the name of the latter compound has been still further abbreviated to triac (Trotter 1955)

Both compounds were assayed physiologically by Pitt Rivers (1953) using the goitre-prevention test in rats Both had about a tenth of the activity of triiodothyronine, and it was shown that triac, given by daily injections, raised the oxygen consumption of intact rats

Thibault and Pitt-Rivers (1955) have shown that, unlike thyroxine and triiodothyronine, triac appears to have an immediate effect on the oxygen consumption of kidney slices in vitro, and the same workers described an increase in the oxygen consumption of thyroidectomised rats only two hours after a single injection Roche et al (1955) have identified triac in kidney slices incubated with ^{131}I-labelled triiodothyronine It is therefore possible that triac is normally formed from triiodothyronine in the body, and that the oxidative deamination and decarboxylation of triiodothyronine to triac are an essential step in the process by which the thyroid hormones exert their action on the tissues

Triac is therefore a substance of considerable physiological interest, and it became desirable to know something of its action in man It was first administered to man by Lerman and Pitt-Rivers (1955) They gave repeated injections to 2 patients with myxœdema The undernutrition and unemployment. For example, Barbados which has fully developed its agricultural resources and can hardly increase its income or food-supply any further, had a 1953 population of 221,000 in its 166 square miles. Since 1921, there has been negligible change in its birth-rate but the annual death-rate has fallen from 33 per 1000 population to 14 per 1000 in 1953, resulting in an annual rate of population increase which rose from 0·2% to 1·9% over those years and which is still rising proportionately.[3] And things are much the same in most of the other West Indian islands. If medicine upsets so rudely a stable natural balance, it must join in the efforts to restore a new balance, and the doctor must share the social responsibility in this change with pioneers in other fields. What is now needed is a corresponding success in the bigger and more difficult task of combating the disabling diseases, where malnutrition and psychiatric ills, both intricately linked with social problems, play a very important part.

The Caribbean is sparsely doctored. In Jamaica, for example, there is *only* 1 qualified doctor to every 4000 people.[4] The University College of the West Indies can remedy this in the course of time, but only if local schools provide an adequate input of capable students. It is right that when there are suitably qualified West Indians available they should run the medical services, teaching, and research; but it is equally wrong to court a danger of parochialism. A free exchange of medical men and women between this country and the West Indies is to be encouraged by every means. In research, the Medical Research Council and the Colonial Office are already following the admirable policy they started in Africa, whereby activities and funds are to be coordinated through a local medical research committee. Above all else there is need for continued unity of purpose in these widely separated but closely linked lands: if the recent conference heralds this for medicine, it may well have been an historic occasion.

DEADLY SWEETS

A RECENT inquest[1] on a child who died of ferrous sulphate poisoning is another reminder of the disturbing number of accidental deaths caused by drugs. Iron, barbiturates, and antihistamines, three of the most dangerous groups of drugs,[2] are among those which appear as attractively coloured sugar-coated tablets. Elliot[3] has lately discussed this sinister modern tendency to make drugs look like sweets. When the drugs are intended primarily for adults such methods of presentation are indefensible.

In recent years a wide range of drugs has been introduced solely for children; and sedatives, analgesics, sulphonamides, and antibiotics are among those now appearing as attractively coloured and flavoured suspensions or tablets designed to appeal to the childish palate. If these preparations enable children to be effectively treated at home rather than in hospital, or eliminate the psychological trauma of repeated injections, they are welcome. But their potential danger must be thoroughly appreciated.

The problem of accidental poisoning will not be solved by reproaching the manufacturer. Indeed Fraser[4] has suggested that the attractive appearance of drugs may not in fact be as decisive as is generally supposed; and this view is supported by the interesting work of Craig[5] on the type of child who swallows poisons. He points out that those children who are very keen on putting things in their mouth are likely to poison themselves indiscriminately, although an attractive tablet or medicine is an added temptation. Some infants will eat the most unpleasant things, and often do so whenever they are allowed access to them. The insecurely guarded family medicine chest with its assortment of harmless placebos and potent drugs—legacies of long forgotten ills—is a menace. The garden shed and the cleaning drawer contain dangerous chemicals, and in a doctor's household there is the collection of unopened samples. Secure screw-topped bottles, locked cupboards, and the disposal of unused drugs provide some safeguard; but the final remedy must lie in wider education of both parents and doctors. Parents must be repeatedly reminded that the exploring toddler is at great risk and that it is not only drugs labelled "Poison" that are dangerous.

Reports of success with heroic measures in the treatment of poisoning by ferrous sulphate[6] and barbiturate[7] among others, suggest that lives might be saved if action was swifter and surer. In some cities in the United States, "poison centres" have been set up where immediate information can be had about the toxic ingredients of drugs and household preparations and the best treatment. These centres can collect valuable statistics, and could be a source of authoritative propaganda to doctors, clinics, and the press.

But such measures will not immediately improve a situation for which the inaction of doctors is at least partly to blame. The replacement of all attractively coloured and flavoured drugs of potential danger by something less deceptively decorated is long overdue, and is the most effective single step we can take towards preventing these tragedies.

THIOPENTONE IN OBSTETRIC ANÆSTHESIA

FOR many years most obstetricians and anæsthetists have accepted the view that drugs given to the mother take several minutes to achieve an equal concentration in the fœtus. Thus, the use of intravenous thiopentone for operative obstetrics has usually been an indication for a speedy delivery to avoid the risk of the drug's depressant action affecting the child. Indeed, much of this opinion has been based on theory rather than proven fact, though there is some evidence in its favour.[8] Most experienced anæsthetists and obstetricians would probably agree, however, that a small dose of thiopentone, used only for the induction of anæsthesia, does little to a healthy child no matter how long after the injection the baby is delivered.

Crawford[9] has lately recorded the results of an investigation of maternal and fœtal serum thiopentone levels in 41 cases during delivery. (Dr. Crawford's contribution to the correspondence on anæsthesia in obstetrics appears on p. 913.) He found that the fœtal serum

Results

Myxœdema

Before attempting to compare the effects of triac on the blood-cholesterol level and B.M.R. it was necessary to get some idea of the speed and duration of its action. If, as experiments on animals suggest, its action is both more rapid and more transient than that of the other thyroid hormones, the time interval between the administration of triac and estimation of the B.M.R. might be critical. I have suggested above that the observations of Lerman and Pitt-Rivers (1955) may indicate a greater effect of triac on the blood-cholesterol level than on the B.M.R., but since in their cases the triac was given in the afternoon and the B.M.R. was not measured until the following morning, it might equally well be argued that a sharp but transient rise in the B.M.R. may have taken place undetected in the interval. The same objection might be brought against the present observations, although in this instance triac was given twice daily and the patients were instructed to take the evening dose between supper and bedtime (at the time of estimation of the B.M.R. they were routinely asked whether they had in fact taken the previous evening's dose at the usual time). This criticism would not apply to case 1 while he was receiving 6 mg. of triac daily, because during that time the triac was being given four-hourly day and night, and the maximum effect of triac on the B.M.R. certainly persists longer than four hours. As a matter of fact, it was shown for this patient (Trotter 1955) that, when he received triac 2 mg. daily as a single dose, the time-interval between its administration and the estimation of the B.M.R. could be varied between one and twenty-three hours without affecting the result.

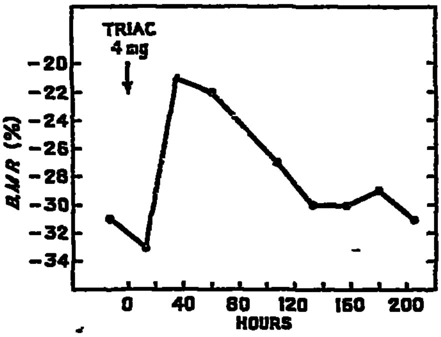

Fig. 2—Effect of single oral dose of triac 4 mg. on B.M.R. in myxœdema (case 2).

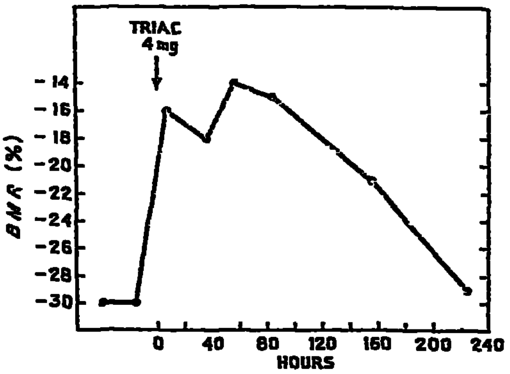

Fig. 3—Effect of single oral dose of triac 4 mg. on B.M.R. in myxœdema (case 4).

The effect of single oral 4 mg. doses of triac on cases 2 and 4 before the patients had received any treatment is shown in figs. 2 and 3. In both patients there was a slight but significant rise in the B.M.R. In case 4 this was already present nine hours after the dose, but in case 2 it was not apparent until thirty-six hours. The B.M.R. remained raised in case 2 for two days and in case 4 for four days. If these patients are representative, it seems certain that, when triac is given at twelve-hour intervals, its effects should be fairly assessed by B.M.R. estimations done from twelve to fifteen hours after the last dose.

Fig. 1 shows the effect of continued administration of triac and of thyroxine in case 1. Both drugs increased the B.M.R. and lowered the blood cholesterol level. With triac 6 mg. daily the blood cholesterol level fell to 150 mg. per 100 ml., yet the highest B.M.R. was only -8%. With thyroxine, on the other hand, the lowest blood-cholesterol level observed on any dose was 225 mg. per 100 ml., but the B.M.R. at the time was +10%. It will be seen that with both drugs the blood-cholesterol level and the B.M.R. varied reciprocally, but in the case of triac a given increase in the B.M.R. was associated with a larger fall in the blood-cholesterol level. It is, however, possible that the comparison of the two drugs is to some extent invalidated because the subject was an inpatient while receiving triac, and an outpatient while receiving thyroxine.

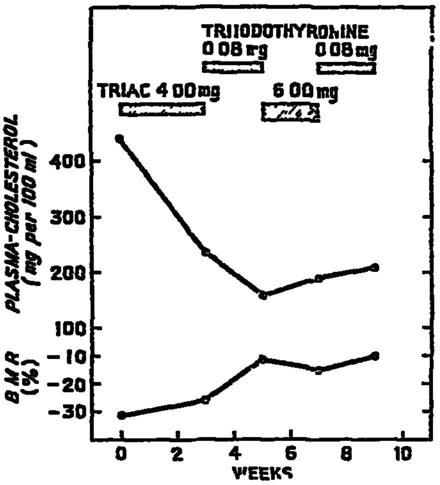

Fig. 4—Effect of triac and of triiodothyronine on blood-cholesterol level and B.M.R. in myxœdema (case 2).

Figs. 4 and 5 show the effects of triac and of triiodothyronine in cases 2 and 3. In case 2 treatment was started with triac 4 mg. daily. This practically reproduced the results of Lerman and Pitt-Rivers (1955), in that there was a substantial fall in the blood-cholesterol level with almost no change in B.M.R. In case 3, however, even 2 mg. of triac daily caused an appreciable rise in B.M.R. as well as a large drop in the blood-cholesterol level. After the initial response had been obtained triac and triiodothyronine were given alternately for two to four weeks at a time. In both cases the relative effect of the two drugs on the B.M.R. and the blood-cholesterol level appeared to be much the same. In case 2, the effect of 6 mg. of triac was similar to the effect of 0·08 mg. of triiodothyronine, as regards both B.M.R. and cholesterol. In case 3, 3 mg. of triac would appear to be roughly equivalent to 0·04 mg. triiodothyronine

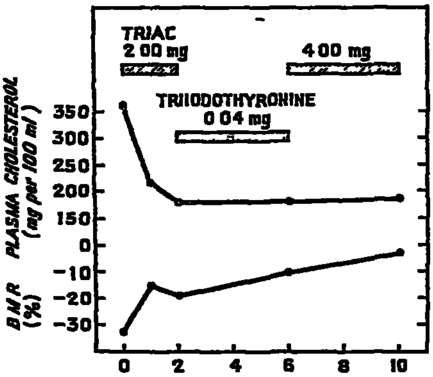

Fig. 5—Effect of triac and of triiodothyronine on blood-cholesterol level and B.M.R. in myxœdema (case 3).

which could profitably be expanded, and which could ensure that when the patient benefits from the operation, his relations and friends do so too

STREPTOCOCCI AND RHEUMATIC RELAPSES

THE antistreptococcal antibody levels in the blood during the first few weeks of an acute attack of rheumatic fever support the view that group A streptococcal infections are a cause of this condition Thus, it is well known that in about 80% of cases the serum antistreptolysin-o titre is raised or rising, and if more than one antistreptococcal antibody is looked for (if, for instance, anti-streptokinase and antihyaluronidase levels are also measured), then the antistreptococcal antibody titre is raised in nearly every case of acute rheumatism[1] In chronic or polycyclic rheumatic fever, the behaviour of the various antistreptococcal antibodies is less well established The strikingly successful prophylactic use of penicillin or sulphadiazine against rheumatic relapses[2] is strong evidence that streptococcal infection is no less important in reactivating than in initiating the rheumatic process yet serological proof of this has often been lacking Some recent studies of Professor Stollerman and his colleagues[3] have related the immune response to streptococcal infection to three clinical manifestations of rheumatic fever—the acute attack, the chronic activity, and the rheumatic relapse

In acute "monocyclic" cases (in which all clinical and laboratory evidence of rheumatic activity had subsided within six months of onset), Stollerman et al found, initially, the expected high incidence of raised antistreptococcal antibody titres In these patients (all of whom were receiving prophylactic antibiotics) they also measured the rate of fall of antibody levels during the twelve months after the acute episode This rate of fall was determined solely by the absence of new streptococcal infection, and not by the course of the disease When a comparison was made between these acute cases and those showing chronic activity in which clinical symptoms had persisted for more than six months, the rate of fall of antibody levels was found to be no different This seems to rule out renewed streptococcal infection as a cause of chronic activity In the third group—the rheumatic relapses—two types of case were differentiated on clinical grounds and they were also distinguishable by antibody tests The first type included the ones which relapsed after withdrawal of aspirin or cortisone therapy All relapsed within two months and 95% within one month of stopping treatment, and none showed increased antibody levels The second type relapsed more than two months after previous activity had subsided, they had all had no prophylaxis and the antistreptococcal antibody titres were newly raised It is clear that it is only in this type of case that reinfection with group A hæmolytic streptococci is primarily responsible for renewal of the disease

Taranta and Stollerman[4] have investigated cases of Sydenham's chorea along the same lines It is known that when chorea is associated with other rheumatic manifestations it usually follows them after a variable period of weeks or months Taranta and Stollerman found, however, the same lag period even when the rate of fall of antibody levels and continuous antibiotic prophylaxis could be said to rule out the possibility of intercurrent reinfection with streptococci In patients in whom the only clinical manifestation was chorea ("pure" chorea) the incidence of raised streptococcal antibody titres was 73% in those studied within one month of onset and 15% in those studied later (one to five months after on While these figures would be low for rheumatic fever a similar intervals after onset, they may, Stollerman suggests, reflect the existence of a long latent period between streptococcal infection and the onset of chorea—a period measurable perhaps in months In America [illegible] points out the peak incidence of chorea in fact follows the peak incidence of rheumatic fever at an interval of one to three months[5]

Although it is hard to determine the precise time of onset of chorea, and to dissociate pure chorea from rheumatic fever with certainty, the evidence suggests that the relation of streptococcal infections to rheumatic fever is close throughout the natural history of the disease Stollerman's work emphasises once more the importance of defence against streptococci at all stages of rheumatic fever

BIRTHDAY HONOURS

THE peerage conferred on Sir Henry Cohen is decorative but also functional Reformed or not, the House of Lords will remain a useful place for explanation and discussion by the expert, and its new member can speak to it with authority on a remarkably large number of medical issues His knowledge of the National Health Service has been gained diversely as physician, professor of medicine at Liverpool, member of the General Medical Council, president of the British Medical Association vice chairman of the Central Health Services Council and adviser to all the Ministers of Health since the service started So great have been the demands made upon him that nowadays no explorer of this part of medicine can go far without finding the tracks of some pioneer Cohen committee in the sand With Sir Henry's immense capability go other qualities that make his friends glad that this new honour should be paid him In his union of quietness with brilliance, of delicacy with endurance, he resembles intellectually the good silver from which, with other kinds of art, he gets so much enjoyment

A second former president of the B M A appearing in the list is Mr Tudor Thomas, whose tour of the association's branches in the Middle and Far East was a notable contribution to its work But it is for his large part in making corneal grafting into a practicable operation that the name of Tudor Thomas is most widely known, and many have reason to be grateful for the surgical research he has pursued so skilfully since the 1920s Another of the new knights, Professor Bedson has had an even longer career of fruitful investigation happily continuing since his academic retirement But whereas his virus studies, particularly of psittacosis earned him the fellowship of the Royal Society, his new distinction chiefly recognises what he has done so much for the organisation of pathology in this country—during the war as a sector pathologist, and since 1949 in succession to the late Sir Philip Panton as chairman of the Central Committee of Pathology at the Ministry of Health Dr Arthur Massey, chief medical officer of the Ministry of Pensions and National Insurance was, like Dr Bedson a combatant officer in the first world war and he first gained a national reputation by his outstanding work for Coventry, where he was M O H for sixteen years including the time of the bomb damage Formerly chairman of the Central Council for Health Education, he is himself a writer and lecturer, and is welcomed as a friend even when he comes as an examiner The last of the four knights, Dr Harkness is less generally known in this country for he reached his present post in the West Indies through appointments in Palestine and in Africa including the directorship of medical services of the Gold Coast and Nigeria With many other colleagues abroad as well as at home whose names appear on p 907, he has our congratulations

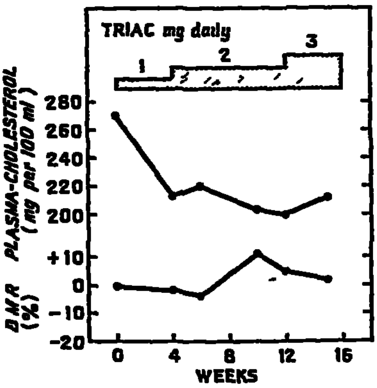

Fig 8—Effect of gradually increasing doses of triac on blood-cholesterol level and B.M.R. in a euthyroid patient (case 6)

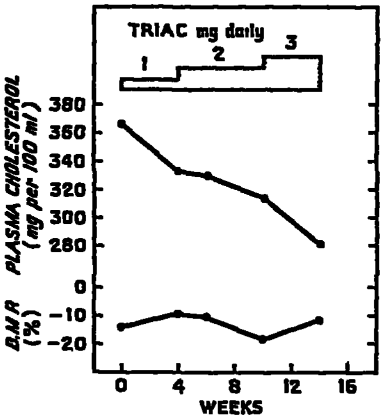

Fig 9—Effect of gradually increasing doses of triac on blood-cholesterol level and B.M.R. in a euthyroid patient (case 7)

with triac showed a fall in the blood cholesterol level. The mean drop in the blood cholesterol level differed significantly from zero at the 1% level in the 2, 3 and 4 mg groups. Analysis of variance showed that the degree of depression by the three different doses was not significantly different. The degree of depression produced by 0·08 mg daily of triiodothyronine was not significantly different from that produced by triac. The present observations have therefore not shown any clear difference between the effect of triac and of triiodothyronine on the plasma-cholesterol level, though they do not exclude the possibility that such a difference would appear in more extensive trials.

Of the 15 patients given triac for two weeks only 1 complained of symptoms suggesting hyperthyroidism. This was a woman treated with 4 mg daily. She noticed palpitations and was found to have lost weight and to have tachycardia. None of the 12 patients treated with triiodothyronine had any symptoms attributable to the drug. The mean weight loss in the triac group amounted to 2 lb., the patients on the small dose of triiodothyronine lost 1 lb. and those on the large dose 4 lb.

DISCUSSION

In 2 cases of myxœdema the relative effect of triac and triiodothyronine on the blood-cholesterol level and the B.M.R. appeared to be similar. In a single case of myxœdema triac appeared to have a greater effect on the blood-cholesterol level relative to the B.M.R., than did thyroxine. It is, however, possible that the results in this case may have been influenced by a change of diet or some other factor, since the patient was in hospital while taking triac, and at home while taking thyroxine. These preliminary trials have therefore not shown any unequivocal difference between the action of triac and of the other two hormones, except that triac is a great deal less potent.

TABLE II—EFFECT OF TWO WEEKS' TREATMENT ON BLOOD CHOLESTEROL LEVEL OF EUTHYROID PATIENTS

Drug	Dose (mg.)	No. of patients	Mean initial blood cholesterol level (mg. per 100 ml.) and S.E.	Mean fall in blood-cholesterol level (mg. per 100 ml.) and S.E.	% change
Triac	2	5	247·8 ± 20·1	83·6 ± 20·7	34
Triac	3	5	222·4 ± 21·8	44·6 ± 9·3	20
Triac	4	5	214·0 ± 13·3	49·2 ± 7·5	23
Triiodothyronine	0·04	7	245·1 ± 18·3	28·4 ± 10·0	12
Triiodothyronine	0·08	5	234·0 ± 14·6	49·8 ± 10·6	21
Controls (dummy tablets)		4	189·3 ± 34·5	0·3 ± 8·5	

In 3 euthyroid subjects with coronary artery disease it appeared to be possible to lower the blood-cholesterol level without materially changing the B.M.R. These results were obtained by giving triac, but the evidence at present available does not exclude the possibility that equally striking effects might have been achieved with the other thyroid hormones in carefully graded doses. It is also possible that the fall in blood-cholesterol level was coincidental, since the trials have not as yet been controlled by observing the effect of discontinuing the drug. Other possibilities are that the fall in blood-cholesterol level is merely a temporary change, or that the initial values for the B.M.R. were erroneously high thus masking a subsequent rise. In any case the small number of patients studied does not permit any generalisations to be made. For these reasons it cannot be claimed at present that triac has any properties not shared by the other thyroid hormones or that it is likely to be particularly useful in lowering the blood-cholesterol level of euthyroid patients. Nevertheless these preliminary trials suggest that a detailed comparison of the effects of thyronine derivatives on blood lipids and on the B.M.R. would be worth undertaking.

Summary

Triiodothyroacetic acid (triac) was given to 3 patients with myxœdema and 18 euthyroid patients.

Its relative effects in lowering the blood-cholesterol level and in raising the B.M.R. have been compared with those of thyroxine in 1 case of myxœdema. Triac appeared to have a relatively greater effect than thyroxine on the blood-cholesterol level.

A similar comparison with triiodothyronine was made in 2 other cases of myxœdema. In these cases the action of the two drugs appeared to be similar, but triiodothyronine was about seventy-five times more effective than triac as regards both depression of the blood-cholesterol level and elevation of B.M.R.

In euthyroid patients triac 2–4 mg daily lowered the blood-cholesterol level by about a quarter. Triiodothyronine 0·08 mg daily had a similar effect. In 3 patients whose dose of triac was increased gradually up to 3 or 4 mg daily, there was no obvious rise in the B.M.R., although the plasma cholesterol level appeared to fall.

Triac reduced the uptake of radioactive iodine in euthyroid patients, the dose required being about twenty-five times greater than the triiodothyronine. This observation is difficult to interpret quantitatively, owing to the relatively large amount of iodine which may be released during the breakdown of triac in the body.

I am deeply indebted to Dr. R. Pitt Rivers for supplying both triac and triiodothyronine, Prof. M. Maizels and his staff for estimations of plasma-cholesterol, and the Sir Halley Stewart Trust for a personal grant.

TABLE II*—PERCENTAGE CONTRIBUTION OF BREAD AND FLOUR TO SOME ELEMENTS OF THE DIETS OF HOUSEHOLDS IN 1954

Element	Households with 1 male and 1 female and					
	Children only				Adolescents only	Children and adolescents
	1	2	3	4 or more		
Calories	25	25	27	29	27	30
Total protein	29	29	31	34	31	35
Iron	25	25	26	29	26	29
Vitamin B_1	31	31	33	35	33	36
Riboflavine	7	7	8	8	5	8
Nicotinic acid	26	26	28	30	26	30

* The figures in this table are derived from the National Food Survey and are provisional only. During 1954 bread made from flour of 70–72% extraction was available in addition to bread made from flour of 80% or higher extraction. Almost all the bread consumed, however, was made from National flour which was required under the Flour Order 1953 to be of 80% extraction or its equivalent.

and iron (table III), but also of a number of other nutrients which are present in wheat but about which less is known. No figures are available to show the extent of the fall of these less well-known nutrients between 80% and 70% extraction flours, but table IV, which gives the levels for white "top patent" flours, indicates that there might be a considerable fall. Those who advocate a policy of fortification in this country do not propose to restore to bread all the nutrients that have been lost by milling to a low rate of extraction. The proposal is to add only iron, vitamin B_1 and nicotinic acid, the implication being that the restoration to flour of other substances is not necessary, under present conditions in this country, even though some of these substances are known to be essential for animal nutrition in planned laboratory experiments. In the opinion of the conference, present knowledge provides no basis *for an assumption such as this*, and past experience should make one cautious of accepting it.

In 1936, when the suggestion was first made that bread in this country should be fortified, the only constituent which it was proposed to restore was vitamin B_1. Ten years later the Conference on the Post-War Loaf [4] recommended minimum values not only for vitamin B_1 but also for iron and nicotinic acid, and the official medical and scientific members held that these values should be attained not by restoration but by retaining the substances during the milling process, so as to include along with them, as far as possible, all the other nutritional factors which might be present in the original wheat. Recent experience with pyridoxine has shown that it would be unwise to neglect the possible nutritional importance of lesser-known or unknown nutrients. When the Conference on the Post-War Loaf met, the nutritional importance of pyridoxine was known only from animal experiments; it has now been shown to be essential to human nutrition, for pyridoxine deficiency has been found to give rise, under special conditions, to recognisable disease in man. In the opinion of the conference it cannot be assumed that this process of discovery is at an end.

The Widdowson/McCance Studies of the Effect of Variations on the Extraction rate

The most recent investigations of the effects of variations in the extraction rate of flour are those of Dr E. M. Widdowson and Prof R. A. McCance.[5]

Their investigations were carried out after the war on children in two German orphanages. For the purposes of the trial, each child continued to receive his full German ration with the exception of the German bread, which was replaced by unlimited amounts of bread made from one of five types of flour specially milled in England: (1) 100% extraction, (2) 85%, (3) 70%, (4) 70% with iron, vitamin B_1, nicotinic acid, and riboflavine restored to the 85% level, *and (5)* 70% with iron, vitamin B_1, nicotinic acid, and riboflavine restored to the 100% level. All contained added calcium. The children obtained up to three quarters of their calories in the form of flour products; the rest of their food consisted chiefly of vegetables and contained very little milk or other animal protein.

TABLE IV*—MEAN CONTENTS OF CERTAIN NUTRIENTS IN FLOUR OF 80% EXTRACTION AND 'TOP PATENT' FLOURS

—	Mean content (mg per 100 g)	
	80% extraction flour (straight run)	Whitest ('top patent' mill streams)†
Iron	1.7	0.9
Vitamin B_1	0.21	0.01
Riboflavine	0.062	0.01
Nicotinic acid	1.7	0.9
Biotin (× 10^{-3})	23	5
Pyridoxine	0.29	0.11
Folic acid	0.026	0.012
Pantothenic acid	0.37	0.33

* Figures supplied by the Ministry of Agriculture, Fisheries and Food.

† No figures are available for flour of 70–72% extraction. The flours in the 'top patent' mill streams varied from 30% to 60% extraction.

Before the investigation began the children had been receiving an inadequate diet and they were in consequence of less than normal height and weight. During the year for which the trial continued, their health improved and their gains in height and weight considerably exceeded those accepted as normal for American children of the same age and sex. This was equally true whichever bread was included in their diets.

In interpreting these results it is important to recognise that nutrients were provided at levels comparable with those of the B.M.A. recommendations ‡ by all the diets irrespective of the type of flour used. It is therefore understandable, although surprising at the time in view of what was thought about the importance of animal

TABLE III—COMPOSITION OF FLOURS NORMALLY USED IN THE U.K. COMPARED WITH THAT OF FLOURS USED IN THE FEEDING TRIALS IN GERMANY

Element	U.K. flours* (mg per 100 g)								Flours used† in investigation in Germany (mg per 100 g)

	12	250

time the B M R and the serum cholesterol level had returned to normal values, although the patient was not yet clinically euthyroid The dosage was increased to 2 mg 6 hourly, further improvement took place within 48 hours, and the patient became clinically euthyroid after two weeks on this dosage The dosage was increased to 2 5 mg 6 hourly for 4 days, with slight further subjective improvement At this stage L thyroxine 0 3 mg daily was substituted for tetrac A bone graft for an ununited fracture of the ulna was performed before she was finally discharged from hospital six weeks after the start of L thyroxine therapy Although she showed only a slight tendency to relapse when tetrac was discontinued, there was a delay of two months before the full therapeutic response to thyroxine was obtained The operation may have been partly responsible for the delayed response

Effect of Tetrac in Euthyroid Subject

Tetrac was given in a dosage of 2 mg 8 hourly for 16 days, after which the dose was increased to 3 mg 8-hourly for a further 6 days A sensation of warmth was experienced about half an hour after the dose, except when it was given in a capsule There was no change in the peripheral circulation, and no other symptoms except intermittent headaches were noted The body-weight remained constant throughout the period of observation except for a transient increase during the initial 48 hours, and no change in pulse-rate or blood-pressure was noted The withdrawal of tetrac gave rise to general malaise, which lasted about a week, and persistent headaches The plasma-cholesterol level was significantly depressed from an initial mean value of 250 mg per 100 ml to 170 mg per 100 ml and returned to its original value a week after tetrac was stopped The values are given in the accompanying table

Discussion

A patient with myxœdema was given tetrac in gradually increasing doses and became euthyroid on a dose of 8 mg daily No attempt to assess the effect of a single intravenous dose was made, because of the previous history of cardiac failure and the unknown potency of this substance It was to be expected that tetrac would have a rapid metabolic action in myxœdema because a single dose raised the metabolic rate of thyroidectomised rats within two hours (Thibault and Pitt-Rivers 1955) A therapeutic response after each increment in the dose was observed within about 48 hours It is unlikely that any sudden change in thyroid status would have been detected with thyroxine given in comparable dosage The absence of a latent period of action implies a rapid rate of degradation, and preliminary observations with ^{131}I-labelled tetrac indicate that the disappearance-rate from plasma may exceed that of triiodothyronine If these observations are confirmed, it may be assumed that equilibrium would soon be reached in response to any alteration in the administered dose, and on the basis of the results obtained in this patient 8–10 mg of tetrac is equivalent to 0 3 mg of L-thyroxine The potency of tetrac in myxœdema is therefore about a thirtieth of that of L-thyroxine

The effect of tetrac on the plasma-cholesterol level of a euthyroid subject is of some interest Strisower et al (1954) have investigated the depression of the plasma-cholesterol level in response to the administration of thyroid hormone They found a significant fall in the plasma cholesterol level of four healthy people given gr 3 of thyroid extract (*U S P*) daily for 2–3 weeks It is surprising that the plasma cholesterol level fell on a dose of tetrac which appears to be less than that required for replacement therapy

It was thought worthwhile to observe whether another quick-acting thyroxine analogue affected the plasma cholesterol level of euthyroid people in a similar way There was no apparent alteration in two such people given triiodothyronine 0 06 mg daily for 10 days, and, when the dosage was increased to 0 12 mg daily for a further week, no significant depression of the plasma cholesterol level was found, although toxic symptoms developed at this level (I J L Goldberg, and A W G Goolden, unpublished) The effect of tetrac on the plasma-cholesterol level in other conditions associated with hypercholesterolæmia is being further investigated

Summary

A patient with myxœdema was given tetrac orally in gradually increasing doses The plasma-cholesterol level and the B M R reverted to normal, and a clinical remission was obtained on a dose of 8 mg daily The latent period of action appeared to be short On the results obtained in this patient it is estimated that the potency of tetrac is about a thirtieth of that of L-thyroxine

A euthyroid subject was given tetrac in about the same dosage as the patient A significant fall of the plasma-cholesterol took place on a dosage less than that required for replacement therapy

I am indebted to Dr R Pitt Rivers, F R S, of the National Institute of Medical Research, for the supply of tetrac, and to Dr I G Gilliland, of the Postgraduate Medical School of London, for permission to treat his patient I wish to thank the personnel of the 7520 U S A F Clinical Laboratory for plasma cholesterol estimations, and Miss Judith Chambers for B M R estimations

" It is interesting to consider how much warmer a family environment the working class baby enjoys in this country, compared with an infant in a better class home The one lives in the centre of the kitchen, which is the centre of family life, and is rarely left alone, in nine cases out of ten he spends the interval from the 6 p m to 10 p m feeds, being nursed and played with, handed round the family circle If mother is ill, or expecting another infant, father frequently takes a week off work and looks after the family In the better class home, 6 p m is a sacred hour at which the infants must be placed in their cots upstairs, after a day spent lying in the garden contemplating the trees, with a brief play-time after tea Father rarely sees his infant for his hours are long and his work responsible he expects to be free to spend his evenings in cultural pursuits beyond the scope of the young If mother is ill, help has to be hired or acquired in some way, as it never even occurs to the father to put his duty to his family before his duty to the community"—Dr BEATRICE WATTS, *College of General Practitioners Research Newsletter* no 11 May, 1956

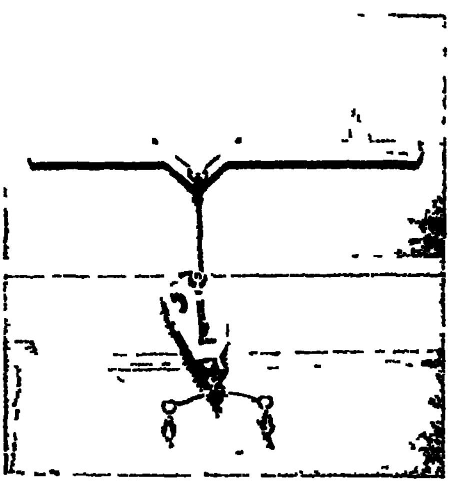

Fig 3—Traverse beam, geared chain hoist, and coat hanger bar

The 'Beem' bed, designed by an American physician, is a more ambitious and expensive piece of furniture (*Nursing Mirror* 1955). It has appropriately been called the "push-button" bed. Tests made in the U S A suggest that there is a saving of 46% of the nurses' time during a *twenty-four-*hour spell of its use. It comprises a self-contained stretcher, a flush toilet, two cabinets for linen, and push-button control within reach of the patient's hand.

Allen (1954) has patented for incontinent patients a simpler bed incorporating a movable centrepiece over a compartment containing a bedpan.

Turner (1954) describes a more elaborate suspended plaster bed frame used at Doncaster Gate Hospital, Rotherham, Yorks. Frames of this type have been specially designed for spinal cases, and the aim has been to make the whole unit mobile and so arranged that the patient can use the various movements at will.

The Standard Sales Co Ltd, Maidstone Building, 74/76, Borough High Street, London, S E 1, manufacture an exceptionally light and mobile hoist (fig 1) operated hydraulically and provided with a safety slow-release valve. The hoisting arm is hinged to the main pillar and the trolley wheels are mounted on a tubular base whose arms can be closed to a minimum of 26 inches, so that the machine can pass through the doorways of a private house. These tubular arms can be spread apart to admit the widest type of invalid wheel chair. Various accessories include canvas or nylon slings for use in a bath or with an aperture for toilet purposes, and an elaborate chair with rests for legs, back, and arms (fig 2). By a simple drill described by the maker a single attendant can prepare a patient, lift him from the bed and lower him into a chair in not more than 5-7 minutes.

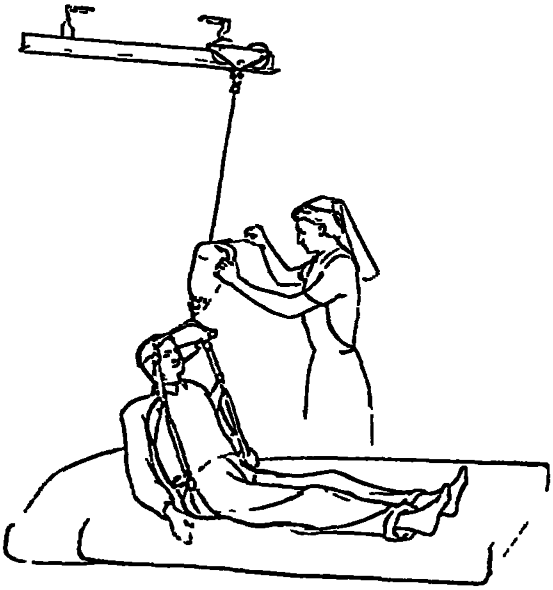

Fig 4—Adjustment of harness

Recently Prior (1956) has described a bed crane specially designed by Mr James Genet, senior orthopaedic technician at Wellington Hospital, for a patient who for six years could not lift herself out of bed or on a bedpan without help. The machine incorporates an ordinary *motor-car hydraulic jack, and the patient* by working the handle can lift herself off the bed or wheel chair and lower herself as necessary. The cost to make it is about £23. The design is not covered by patents of any kind and is available for any hospital to copy.

A New Device

We owe these machines to the efforts of those in attendance on the helpless. A recent device however is of special interest in that it is the invention of a patient, M Watson, a victim of severe poliomyelitis causing extensive paralysis of the muscles of the trunk, almost all the muscles of the arms, and all those of the legs, has devised, with the help of a builder, a machine which enables a single attendant to move him with ease and comfort for every general and special purpose connected with nursing and with no more effort than is necessary to wind an easily worked handle.

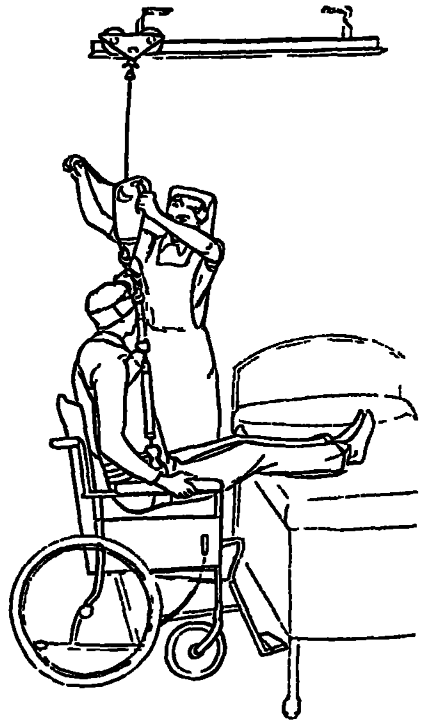

Fig 5—Transference from bed to chair

The webbing harness for attachment to the patient resembles in its general pattern that of most such appliances, but the special features which make it unique in its efficiency and handiness are the use of a traverse beam attached to the ceiling and a geared chain hoist. The beam allows easy lateral movement not only from bed to chair, commode or bath and back, but also, when the patient is in a general ward, transport with minimal assistance from one bed to another limited only by the length of the beam. Indeed if the beam is extended sufficiently the hoist could be used for transport along a corridor to a bath without much difficulty. The geared chain hoist is an adaptation of that used in garage and workshops for raising motor engines.

Fig 3 shows clearly the simplicity and clean line of the appliance unencumbered by vertical upright or a multiplicity of pulleys and ropes which hinder access to the patient for nursing or feeding. Figs 4 and 5 show, in two stages, the procedure of 'bridging the gap' from bed to chair by a helpless patient with the aid of only one attendant. Many other applications of the apparatus easily suggest themselves including lifting for attention to the back, use of a bedpan, insertion of an air pillow, remaking the bed for a helpless

There was also some irregularity of function of his stomach, probably due to the hiatus hernia

The past history and the family history were both negative

Comments

These two cases are put on record to draw attention to the necessity for a full investigation of the œsophagus when pain, which clinically appears attributable to coronary disease, is not associated with any other abnormality, whether clinical, electrocardiographic, or radiological

The proof that in these two cases the pain was œsophageal and not coronary in origin is wanting On the other hand, proof that the pain was coronary is equally wanting Definite knowledge could be obtained only by necropsy, and if the symptoms were in fact due to the œsophageal lesions, it is likely to be unobtainable for many years What is certain is that in each case there was an organic œsophageal abnormality , and we know that " anginal " pain can be a manifestation of œsophageal disorder

The œsophageal condition should be treated by advice about the proper mastication of food, by a low-residue diet, by prescribing aluminium hydroxide or bismuth before meals, and belladonna in full doses, and by raising the head of the bed on nine inch blocks The complete disappearance of symptoms after such treatment would argue for an œsophageal rather than a coronary origin

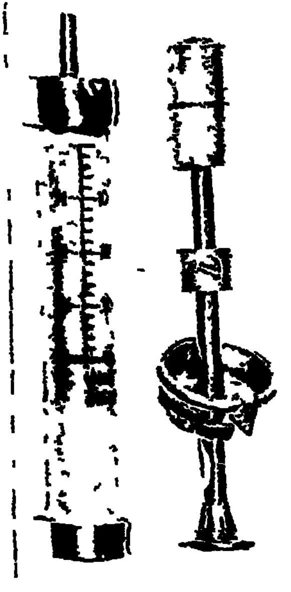
New Inventions

A CHEAP SYRINGE STOP



THERE has long been a need for a cheap and convenient syringe which can be used safely by those with poor eyesight and others who are incapable of drawing accurately up a solution into a syringe

The adjustable syringe stop illustrated appears to meet these requirements It consists of a plated brass collar with a grub-screw The collar can be slipped on to the plunger of any glass-metal syringe and fixed in a chosen position with a screwdriver

Its advantages are that the collar cannot be moved accidentally but is nevertheless easily adjustable by the simple expedient of loosening the grub-screw A syringe fitted with such a collar is cheaper than any other stopped syringe on the market, the collar can be made for a few pence and, if the syringe breaks, can be transferred to any other glass-metal syringe

The collar was made for me and is obtainable from Messrs Whitelaws, 44 Great North Road, Newcastle upon Tyne I am very grateful to Dr C C Ungley and Dr R E Irvine for their help and encouragement

Reviews of Books

The Practice of Medicine

JOHN S RICHARDSON, M V O, M D, F R C P, physician, St Thomas's Hospital, London London J & A Churchill 1956 Pp 1076 40s

MANY students, if asked what they seek most in a textbook of medicine, would probably say, clarity and brevity and they might add that if the writing could have interest as well, so much the better One virtue which students seldom seem to call for, and perhaps rarely feel the need for until they have qualified, is attention to detail and the avoidance of vague generalisations Unfortunately examiners sometimes have a tiresome habit of asking meticulous questions which require exact answers, and the new text which Dr Richardson has edited will arm students against such questions, besides appealing to them on other grounds as well

It is written by fourteen contributors, of whom half are teachers at St Thomas's Hospital, and all may fairly be regarded as belonging to the younger school The writing throughout is clear and up to date There is no padding and for the most part the teaching is firm and authoritative indeed, in places, it may be too brief, and of necessity some subjects receive rather scant mention

It is perhaps significant of our times that psychiatry occupies some 150 pages, while dermatology is omitted as a special subject and the alimentary tract receives only 15 pages—which have a rather defeatist and "passed to you" attitude towards such mainly surgical conditions as carcinoma of the œsophagus and colon The constructive and even optimistic 10 pages and 8 illustrations on occupational diseases of the lungs are remarkably well done There is an excellent short chapter on tropical diseases, and the up to date sections on allergy, collagen diseases, and venereal diseases are also prominent

The index is good and there are useful appendices on, for example, diets, and normal laboratory values It is a notable achievement to produce a book of this size at this price

The authors have not hesitated to express themselves forcibly and it is refreshing to find almost throughout a brisk and practical attitude, with here and there a spark of humour, and a refusal to offer those unconvincing explanations which tend to get perpetuated from textbook to textbook This is a book which undergraduates will find much to their liking

Counseling in Medical Genetics

SHELDON C REED, director, Dight Institute for Human Genetics, University of Minnesota Philadelphia and London W B Saunders 1955 Pp 268 28s

THE Dight Institute of the University of Minnesota was one of the earliest departments to establish a clinic for advising would-be parents on the risks to their children Like some other American genetic counsellors, Dr Reed was trained as a geneticist and is not himself medically qualified Over the course of years, however, he has accumulated considerable clinical experience of the medical conditions in which genetic factors are important, and he has the help of a clinical colleague

In this book he aims to show doctors and the lay public something of the scope of genetic counselling There is an excellent chapter on the philosophy of counselling In common with those doing similar work in America and this country, Dr Reed's practice is never to make decisions for his patients, but to advise them as precisely as possible on the risks and at the same time to put the matter into perspective for them The actual conditions he considers in detail are all common ones, for which in his experience parents often seek advice—mental defect, psychosis, and some of the congenital malformations Some illustrative case histories are given at the end of each chapter Information on the rarer conditions is given in an appendix, which is taken from a recent paper by Dr F C Fraser, of Montreal

This is not intended to be a textbook and anyone wanting information on a particular condition, with no

The council considered in camera the question of the admission to examinations held by licensing bodies of practitioners whose names have been erased from the Medical Register

On resumption in public, Dr J P HEDLEY, the senior treasurer, presented the report of the finance committee In 1955 total expenditure was £7948 greater than in the previous year, income exceeded expenditure by £3926 The increased expenditure was almost wholly attributable to a special allocation of £5000 towards the heavy expenditure which was at present being incurred on the visitation and inspection of examinations and the visitation of medical schools, and an increase of about £2745 in fees and allowances paid to members in accordance with revised arrangements approved by the Treasury

Dr H GUY DAIN presented the report of the pharmacopœia committee He said that the British Pharmacopœia Commission was preparing lists of drugs to be added to or omitted from the *British Pharmacopœia* in the 1958 edition The omission of a drug from the *Pharmacopœia* did not preclude its inclusion in the *Codex*, and some drugs left out last time were to be included this time, indicating that ideas of usefulness might change even in five years

Medical Disciplinary Committee

The committee began its session on May 30, under the chairmanship of the President There is to be an additional session in July

APPLICATION FOR RESTORATION

William Arthur Chanmugan Nason made application for the restoration of his name to the Register The application was rejected

FURTHER POSTPONEMENT

William Frank Cruickshank, registered as of c/o Milne, Brown Cottage, Westmuir, Brechin, Angus, M B Glasg (1935), did not appear for an adjourned judgment and was not represented In May, 1954, he had been found to have been convicted of being drunk and disorderly and to have been guilty of failing to visit or treat patients neglecting over a considerable period his duties as a medical practitioner under the National Health Service, and disregarding his personal responsibilities to patients Judgment was then postponed for a year, but last May the committee found that the evidence so far received concerning his habits and conduct would not warrant it in discharging the case and judgment was further postponed until the present session

Mr G J K Widgery solicitor to the council read a letter in which Dr Cruickshank stated that he was unable to attend Since judgment had been postponed last May, Mr Widgery said there had been a further conviction, when Dr Cruickshank was fined £15 and ordered to pay costs for being under the influence of alcohol to such an extent as to be incapable of being in charge of a car

In order to give Dr Cruickshank a further opportunity of being present, the committee postponed the case until its meeting in July "In his own interest he should be present on that occasion," added the chairman

CONVICTION FOR ASSAULT

Convictions for assaulting Isabella Gourlay Nicol or Whitelaw and conducting himself in a disorderly manner and committing a breach of the peace were admitted by *James Watson Richmond*, registered as of Rosskeen Kelty, Fife M B Glasg (1929) He had been fined at the Sheriff Court of Fife and Kinross at Dunfermline £12 on the first charge and £4 on the second with the alternative of 40 days and 20 days imprisonment to run consecutively

Mr Widgery recalled that Dr Richmond was convicted of similar offences in 1952 relating to three young women who were patients At the same Sheriff Court he was fined £25 He appeared before the committee in November, 1952, when he said that he was having treatment Judgment was postponed for a year and then the case was dismissed

The Chairman announced that the committee took the gravest view of a conviction of this sort and this was the greater because of the earlier convictions of a similar nature but in order to give him one further opportunity of reconsidering his habits and conduct it had postponed judgment for two years, until May, 1958 He would be required to appear in May, 1957, and before that date he would be asked to furnish the names of colleagues and other persons of standing to whom the committee could apply for testimony as to his habits and conduct

ADULTERY

Ernest Benjamin Dawe, registered as of 235, Downham Way, Bromley, Kent, M R C S (1941), was charged with an improper association with a patient, which had led to his being found guilty of adultery in the Divorce Court The Chairman announced that the committee found Dr Dawe guilty of infamous conduct in a professional respect and ordered his name to be erased from the register This is subject to appeal within 28 days

John William Pooley, registered as of Nunswell House Boney Hay, Walsall, Staffs, M B Birm (1939), appeared on a charge of infamous conduct in a professional respect

Mr John Hobson, instructed by the council's solicitors, read a letter from Dr Pooley admitting that he had had intercourse with a young woman who was on his list and that he was the family doctor of her father, but denying that he stood in professional relationship to the young woman and stating that it was untrue that he gave her medical treatment Intimacy arose solely from her being a domestic servant in his house, the fact that she was on his list was wholly irrelevant

At the close of the case for the complainant Mr N Leigh Taylor, solicitor of Messrs Hempsons, submitted that there was insufficient evidence of which the committee could find Dr Pooley guilty, and that the facts were not such as to constitute infamous conduct in a professional respect Was it possible to say that merely because a person was on a doctor's list there was then a professional relationship? Suppose a person went on a list and had all his treatment privately Mr Hobson had referred to Dr Pooley's obligations under the regulation to treat the young woman as a patient, but that liability only arose if she asked for treatment, and there was no evidence that she did so

The committee found Dr Pooley not guilty of infamous conduct in a professional respect

Frank Stanley Mellows, registered as of 63, Hatherley Road Cheltenham, M B Camb (1948), admitted committing adultery with a patient The committee found him guilty of infamous conduct and ordered his name to be erased He has 28 days in which to appeal

DRUG OFFENCES

John Millar Matthew, registered as of 176 Farley Road, Selsdon, Surrey, M B Camb (1932), was charged with a conviction in 1948 of failing to keep records of dangerous drugs, when he was fined a total of £300, with convictions in 1954 of unlawfully prescribing, supplying and possessing dangerous drugs when he was bound over in the sum of £5 for three years, and with a conviction in February, 1956 at the Stevenage Magistrate's Court of driving a motor car when under the influence of drink or drugs, when he was fined £20 ordered to pay £27 1s costs, and disqualified from driving for five years

In order to give Dr Matthew an opportunity to overcome the tendency which led to the convictions, the committee postponed judgment for a year

NAME NOT ERASED

In view of the satisfactory information concerning his habits and conduct which the committee was gratified to receive it did not direct the erasure of the name of *Ralph Martin Ca*, registered as of 71, Gillott Road Edgbaston, Birmingham, M B Birm (1934) Judgment had been postponed for a year to give him one further opportunity of overcoming his tendency to abuse of dangerous drugs following a conviction for procuring dangerous drugs in 1953

MOTORING OFFENCES

William James registered as of Parc y Ddol College Road Carmarthen M R C S (1912) had had judgment postponed for a year He had been convicted in 1953 and 1955 of being in charge of a motor vehicle while under the influence of drink When judgment was postponed last year the chairman said that Dr James should make every effort to be present when his case was again considered

The Registrar was not directed to erase Dr James's name

DANGEROUS DRUG CONVICTIONS

Joseph Hirschmann registered as of Upper House Clunbury Craven Arms Salop, M B Dubl (1920) had had judgment

Public Health

HEALTH VISITING

Working Party's Report

The working party which has been inquiring into health visiting has now issued its report[1] The working party was set up under the chairmanship of Sir Wilson Jameson in 1953 by the Ministers of Health and Education and the Secretary of State for Scotland * Its terms of reference were "to advise on the proper field of work, the recruitment and training of health visitors in the National Health Service and School Health Service" Its report is part of a review of the work, recruitment, and training of domiciliary visitors in the field of health and welfare An inquiry into the work, recruitment, and training of social workers in this field is now proceeding, under the chairmanship of Miss Eileen Younghusband

FUTURE WORK OF HEALTH VISITORS

The working party concluded that work with mothers and young children, with school-children, and with the tuberculous will continue to be important but that the emphasis will change More attention should be paid by health visitors to the mental-health aspects of maternal and child care and more help given with the problems of handicapped and maladjusted school-children On the other hand, inessential duties must be avoided and time concentrated on essentials The same health visitor should be responsible both for the young child at home and the child at school

The health visitor must be closely associated with the work of the general practitioner not only in her traditional fields but in relation to care and aftercare generally She could come to be useful in any part of a family doctor's practice, in the exercise of her proper functions The working party note with approval the wide support for a domiciliary team of which the family doctor would be the clinical leader, and they believe that the health visitor should play a central part in such teams

In all her work, the health visitor should have regard to the psychological aspects of what she is doing, and especially in her work with mothers and young children she can make an important contribution to mental health It is unlikely that the *problems of established* mental illness will be in her competence

It follows from her association with general practice that the health visitor may be in touch with a vastly wider range of families than hitherto While the working party reject the possibility of an omnicompetent family visitor, they feel that the future health visitor can serve a general purpose in her family visiting She would act as a common point of reference and source of standard information, a common adviser on health teaching, a "common factor" in family welfare—and to that extent a general-purpose family visitor

THE PRIMARY AIM

Primarily, the report says, the health visitor's functions are those of health education and giving such social advice as will enable the family to benefit from her advice on health She will carry out her other functions of cooperation with other workers incidentally to her main purposes She is not to be described as a social worker nor, in general, to practise as a nurse or midwife, and a recognition of her proper status will be important if her work with family doctors is to be fully effective Again, because of the new link with general practice the health visitor will increasingly be concerned with families where some form of social action is needed She should be trained, however, to recognise the limitations of her skills in this direction, to see that the appropriate worker is put in touch with the case, and to cooperate in any way required

TRAINING

The working party regard as undesirable, but for some *time inevitable*, the *present three-part training in* nursing, midwifery, and public health Midwifery training could be replaced by a special three-month course Nurse-training is open to criticism as a preparation for health visiting, but it is still the most convenient means of gaining the essential medical background, and the objections are not insuperable On the other hand, the total length of training—four years or four years and three months—is likely to deter school-leavers and others who, the working party hope, will be eventually the main source of recruits They therefore hope that training for health visiting will prove a fruitful source of experiments designed to reduce the length of nurse-training—the main stumbling-block They *strongly support* the institution of integrated training courses embodying all the elements of the three trainings essential to health visiting, and designed for health visiting as a career

The public-health element in the training should take between nine months and a year or the equivalent It should aim not at covering the whole possible field and producing a finished worker but at introducing the future health visitor to the principles and including as much practice in their *application as possible* Special attention should be paid to the mental-health aspects of her work with families, to the *problems of* cooperation with other workers, and to the techniques of health education

Arrangements will be necessary for providing further training and retraining of existing staff for their new rôle If the report's suggestion of a "group adviser" grade for health visitors of exceptional ability is accepted, diploma courses will be needed for future group advisers

Organisation of Training

The working party recommend the establishment of new central training bodies—possibly based on the organisations of the present examining bodies The new bodies would prescribe the syllabus and arrange examinations, constitute training centre committees to run courses of training, and approve their arrangements Some 25 to 35 courses would be needed *each year, more than one* being run by one committee if necessary An important function of committees should be the final selection of students

---

[1] An Inquiry into Health Visiting Report of a working party on the field of work, training and recruitment of health visitors H M Stationery Office Pp 183 6*s* 6*d*

* The other members were Dr A Beauchamp, vice chairman, Birmingham Executive Council, Alderman Mrs K Chambers, chairman, Bradford Health Committee and Bradford Executive Council, Miss E W Himsworth, county nursing officer, Midlothian and Peebles, Miss E Stephenson, chief nursing officer Newcastle upon Tyne, Dr J F Warin, medical officer of health and principal school medical officer, Oxford

THE LANCET
LONDON SATURDAY, JUNE 9 1956

The Millers Decide

"In this country," said the Medical Research Council conference, "bread is the largest and most important single item of the diet, providing between one-fifth and one-third of the calories and protein and a high proportion of other essential nutrients ' As a protective food, bread is particularly valuable to people who cannot afford a good mixed diet, and therefore to children of large families Hence a reduction in the nutritional value of bread may have consequences which, though not readily perceptible, are none the less grave, and in authorising such a reduction the Government risk damage to the public health The decision by which they are now abandoning 80%-extraction National flour in favour of "enriched ' or "fortified " flours of a lower extraction has the backing of a highly expert panel,[1] but it is contrary to the opinion of their own medical advisers and of the M R C conference whose evidence we publish on p 901 Moreover, the scientific weight to be attached to the panel's conclusions is lessened because these seem to be based on administrative rather than purely nutritional considerations—on what the panel thinks practicable rather than what it thinks desirable The report was in fact written in the knowledge that the flour-millers are determined that bread shall be white, and have already abolished National flour by quietly altering the composition of what is sold under that name The extraction-rate of National flour has already come down generally from the 80% (or its equivalent) specified under the Flour Order 1953 to about 74%, for enforcement of the order has been prevented by the need to allow a wide range of variation in the vitamin content of high-extraction flour—which makes it very hard to prove that a particular batch is at fault In face of the "continuing fall" in the vitamin-B_1 and nicotinic-acid content of National flour since decontrol, which it attributes primarily to "deliberate disregard of the intention of the Flour Order," the panel evidently feels that we should cease to bother about extraction-rates (which only the millers can control) and should make sure, by enforceable regulation, that they enrich their white flour with at any rate the three "token nutrients '—iron, nicotinic acid, and vitamin B_1 The national policy of high extraction—adopted on grounds both of economy and health—is to be replaced by a weaker policy of fortification The millers have virtually settled the matter for themselves—though it must be pleasant for them to have the Government's approval

The degree of freedom that ought to be allowed to the man who processes and distributes food is going to need further thought On the one hand, the public often has to thank him for making his product convenient, cheap, and readily transportable, but on the other hand there is no doubt that these qualities assume a higher place in his calculations than the damage he may be doing to the nutritional value of the food The flour-millers, for example, have earned respect by their enterprise and many of their services to the nation, but from the standpoint of the nutritionist their treatment of bread has been irresponsible To nutritionist and layman alike, it seems obvious that before someone, for reasons of convenience, alters the character of a staple food, the onus lies on him to show that the change at least does no harm but it sometimes seems as though the modern food-processor thinks himself entitled to do what he likes with his product—after which the onus lies on someone else to prove his process dangerous or damaging At the time when the flour-millers first produced their chemically treated low-extraction white flour, they were not alone in the illusion that this was a genuinely superior product but it is harder to forgive the tenacity with which they have stuck to their original mistake, and have resisted efforts to make their flour safer and more nutritious The onus rested chiefly on Sir **Edward Mellanby**, they felt, to show good cause why they should not continue to use a flour-improver, agene, which causes fits in dogs, and though he won at last a posthumous victory, and the use of agene was forbidden, we do not know how confidently we can rely on the substitutes now in use In the late 1930s, after the worst period of unemployment, it had become clear that impoverishment of the flour had harmfully reduced its content of vitamin B_1, and its enrichment with this particular vitamin was proposed As a further concession, it later had to be admitted that people relying on the 72%-extraction flour which was current before the war might be missing some of the iron or nicotinic acid they needed from their bread so these have now been added And no doubt, as knowledge grows, and the millers are gradually shifted from their positions, we shall be allowed further instalments of the nutrients which they have removed

The expert panel's report sets out the arguments very ably and burkes none of the issues Why then should it come down on the side of supplying the public, henceforward, with fortified white bread? First, perhaps, because the panel was too ready to believe that the public (as well as the bakers and the millers) are eager for low-extraction flour Secondly, because the panel thought the industry possibly right in saying that if people can obtain only bread made from 80%-*extraction* flour they will eat less bread and more of other manufactured foods which may be less nourishing Thirdly, because, with *fortification*, we know just where we are a true 80%-extraction flour may give a more widely spread insurance against possible, but as yet unproved, deficiency in the diet, but the 70%-*extraction enriched flour* "gives a more *certain* cover against possible deficiency of the three ' token ' nutrients with well recognised deficiency states" These are substantial reasons, and so is the fact that the millers have virtually ignored the Flour Order and cannot easily be made to obey it Yet with all respect we say that the panel has given the wrong advice As a result of that advice, bread is to be slightly more reliable as a source of iron, vitamin B_1, and nicotinic acid, but it will contain less of certain in a subacute form, or (c) clinical recovery with the later development of cirrhosis of the liver The ætiology has not been finally established but the evidence points to certain bush teas, particularly those made from *Crotalaria retusa* and senecio as being important factors Cooperation with the veterinarians has proved profitable

---

[1] Report of the Panel on Composition and Nutritive Value of Flour Cmd 9757 H.M Stationery Office 1956 See *Lancet* May 26, 1956 p 800 The members of the panel were Sir Henry Cohen F R C P (chairman) Prof A C Chibnall, F R S Prof J H Gaddum M R C S F R S, Prof R A Morton F R S, and Prof L J Witts F R C P

The pathological and histological features were presented by Dr G **Bras** The essential change, which he was *the first to describe*, is occlusion of the small hepatic veins by intimal swelling, with resultant centrilobular *congestion and death of the liver cells* Injection of the hepatic veins with radio-opaque material has demonstrated and confirmed the site of the obstruction very beautifully The vascular change is not found elsewhere in the body In the chronic stage the cirrhosis which develops is non-portal in type, as distinct from Laennec cirrhosis

VOMITING SICKNESS

The pharmacological and biochemical aspects of vomiting sickness and its relationship to ackee poisoning[2] were presented by Dr P **Feng** and Dr S J **Patrick** This condition develops acutely, mainly in young children Vomiting is not a striking feature but clouding of consciousness always occurs and may proceed to coma Severe hypoglycæmia is a constant feature Two polypeptides, hypoglycin A and B, have been isolated from the ackee, and they produce severe hypoglycæmia in animals In these animals the outstanding clinical features are vomiting, drowsiness, coma, and death Rats fed on a low-protein high-carbohydrate diet ("a Jamaican type diet") are more sensitive to hypoglycin A than rats fed on a normal diet In the rat, hypoglycin A reduces the total carbohydrate stores of the body Liver glycogen falls almost to zero, but muscle glycogen is not greatly affected Synthesis of glycogen by the liver is impaired The ackee-poisoned rat converts very little radioactive glucose into muscle glycogen or fat and most is excreted as CO_2 Pathologically one of the most interesting findings is destruction of the α cells of the pancreas The ackee is probably only one of the factors responsible for this condition

A NEUROPATHIC SYNDROME

Prof E K **Cruickshank** discussed the clinical features of a neuropathic syndrome studied at the University College Hospital The four main features are (*a*) upper motor neurone damage, (*b*) damage to the first sensory neurone, (*c*) retrobulbar neuropathy, and (*d*) eighth nerve deafness The onset is from the second to the sixth decade and may be sudden or gradual The sex incidence is equal Maximum incapacity develops within a few months and the disease thereafter seems to be stationary The diet of the patients varies from good to very poor, but few show overt signs of vitamin deficiency or malnutrition A dietary factor is possibly responsible but there is no definite evidence of this No pathological material has as yet become available for study This, and the related condition of tropical amblyopia described by Dr D W A **Degazon**, are by no means rare in Jamaica, and constitute a public-health problem of some importance On the other hand, demyelinating diseases familiar in Europe, such as disseminated sclerosis, are very uncommon

SOME OTHER PAPERS

In the field of malnutrition, Dr E H **Back** outlined a nutritional survey amongst small farmers in Jamaica, Dr B L R **Symonds** described the clinical syndrome of "sugar baby" in Trinidad, and Dr J **Waterlow** discussed the assessment of protein deficiency in man

Mr R P M **Miles** described the high incidence of rectal stricture in the female in lymphogranuloma venereum, Mr J S R **Golding** gave a survey of bone and joint disease in Jamaica, emphasising sickle-cell disease as a cause of osteomyelitis Dr B B G **Nehaul** of British Guiana, described the clinical manifestations of filariasis, and Dr J A. **Tulloch** discussed certain aspects of diabetes which may be peculiar to the West Indies and outlined the investigations being carried out

FERTILITY AND STERILITY

The Second World Congress on Fertility and Sterility sponsored by the International Fertility Association was held at the Congress Palace of the Mostra d'Oltremare Naples, Italy, from May 18 to 26 It was attended by over 1100 people, representing 68 countries

Implantation of the Ovary into the Uterine Cavity

B S **ten Berge** (Groningen, Netherlands) discussed whether intra-uterine ovarian implantation should be resorted to in cases where both fallopian tubes are absent This procedure has been recommended by several gynæcologists, and pregnancies have occasionally followed, though only in a very small proportion of cases The gynæcologist should not perform this operation unless he is confident that ill effects are unlikely Harmful complications may include postoperative uterine fistula, which may cause leakage of menstrual blood, with formation of adhesions and resulting pain and discomfort A further danger is weakening of the uterine wall with rupture due to stretching during an ensuing pregnancy In 16 patients, in whom this operation was performed subsequent culdoscopic examination proved the absence of adhesions to date none of these patients have become pregnant

Organic Cornual Occlusion of the Tubes

V B **Green-Armytage** (London) said that it is not uncommon in subfertility cases to get a history of abortion before marriage or in the early years of marriage Very often in these cases there is cornual occlusion After excision of the occluded portions, he recommended surgical implantation of the terminal portions of the tubes, with the assistance of solid 'Polythene' rods these may be brought down into the vaginal canal and left there for six weeks

Plastic Operations on the Fallopian Tubes

J P **Greenhill** (Chicago, Ill) reported that, from the literature and personal letters from a large number of gynæcologists interested in plastic operations on the fallopian tubes, he obtained data concerning 2113 such operations There were 405 pregnancies (19%), or 1 pregnancy following every 5 operations There were only 313 living children or 1 living child after every $6\frac{1}{2}$ operations There was 1 ectopic pregnancy after approximately every 6 operations While the results are far better than they were twenty years ago, they are still far short of what they should be to justify indiscriminate plastic tubal operations Furthermore, a high incidence of tubal pregnancies follows these operations

Latent Genital Tuberculosis

I **Halbrecht** (Petah Tiqvah, Israel) investigated 170 cases of tubal occlusion in primary sterility In 68 of these cases, genital tuberculosis was discovered Cultures of menstrual and intermenstrual discharges were employed In 17 out of 27 cases which received combined treatment with streptomycin and *p*-aminosalicylate, there is no evidence of genital tuberculosis four to five years after the treatment

Duration of Function of Corpus Luteum

H H **Knaus** (Vienna) recalled that in 1929 he demonstrated that ovulation takes place on the fifteenth day before the succeeding menstruation, the activity of the corpus luteum normally persisting for fourteen days In cases of sterility, this activity does not last fourteen days, and in consequence, even when the ovum is fertilised, the conditions for proper implantation are not adequate There is no real essential regularity of the length of the menstrual cycle, but there is a real regularity of the activity of the corpus luteum, have a relatively greater effect in depressing blood-cholesterol than in raising B M R Thus, Dr GOOLDEN has shown that a dose of tetrac no greater than is required for the replacement therapy of myxœdema was capable of causing a sizeable drop in the blood-cholesterol of a euthyroid subject Similarly Dr TROTTER has shown that triac was able to lower the blood-cholesterol of 3 euthyroid subjects, without a significant increase in B M R He is hesitant, however, about ascribing these effects to the acetic-acid side-chain, because falls in blood-cholesterol of similar magnitude were produced with triiodothyronine Whatever the significant feature of the molecular structure may be, the fact remains that the new compounds show some promise of being able to lower blood-cholesterol without causing unwanted side-effects If further work confirms these observations, it might be possible to contemplate a large trial designed to test the proposition that lowering the blood-cholesterol will reduce the incidence of coronary-artery disease

---

Medicine in the Caribbean

SINCE the recommendations[1] of the Asquith Commission on Higher Education in the Colonies, and of its West Indies committee under Sir JAMES IRVINE, were published in 1945, a University College of the West Indies has been established in Jamaica with faculties of arts, science, and medicine A modern teaching hospital of over 300 beds has been built and staffed from this college, and its clinical instruction was recognised by the University of London as being of sufficiently high standard for the London M B (which was passed by 13 out of the first 15 of the college's students who sat the examination) Moreover, wide research has been put in hand and has already produced notable results, as a recent conference (briefly reported on p 909) reflects But this conference did more than demonstrate these achievements of the University College of the West Indies excellent contributions also came from members of the medical services of the different territories of the British West Indies—contributions which bring credit to the local government medical services and to those who have supported the work from this country and the United States

If the full significance of this medical conference is to be appreciated, it must be viewed against the geographical and social background of the Caribbean Many of us in Britain are apt to forget the enormous sea distances between the countries and islands which make up the British West Indies They form a vast semicircle, which covers over 2000 miles, starting on the central American mainland in British Honduras, and passing through the Cayman Isles, Jamaica, the many Leeward and Windward Isles, Barbados, and Trinidad, to end at British Guiana on the northern coast of South America We forget that the journey from Jamaica to Trinidad is roughly the same distance as that from London to Moscow or Istanbul Yet these scattered lands are closely linked racially, less than 5% of their peoples are of unmixed European descent, and the majority are African Negroes, with a small proportion of East Indians and Chinese They are also linked economically through their agriculture, all of them primarily grow sugar or bananas, with smaller quantities of citrus fruits (Trinidad stands alone in having a rich supply of oil and asphalt) A tropical climate modified by the closeness of the sea is common to them all, and they share too the same historical development It is hardly surprising, therefore, that they have the same medical problems

Anyone from Britain visiting a general hospital in the West Indies would be struck by the amount and variety of the diseases that can be studied there, but nearly always there are the dreadful complications of poverty and malnutrition to modify the clinical picture and hamper treatment Yet, superficially, the similarities to British medicine are perhaps more striking than the differences Typhoid fever, malaria, sickle-cell anæmia, lymphogranuloma venereum, and some specific effects of malnutrition (especially in children) would be the only unfamiliar diseases that the British doctor would commonly see in the general hospital And he would note with interest the extreme scarcity of emphysema, mitral heart-disease, and neurological conditions such as disseminated sclerosis, subacute combined degeneration, and tabes (despite the prevalence of syphilis) On the other hand, acute lobar pneumonia, paraplegia (often due to cervical spondylosis), acute rheumatic fever (in contrast to the rarity of mitral stenosis), hypertension and its complications, and (possibly linked with hypertension) eclampsia are common

The challenge has been ably taken up Malaria has been almost completely eradicated from British Guiana, and at the conference Dr GIGLIOLI described the long work that has led to this great success, to which he has notably contributed Again, the nature of Jamaican "vomiting sickness" has been largely elucidated[2], a new form of liver disease, called venous-occlusive disease, has been described and investigated, research in virus disease in Trinidad and in yaws in Jamaica has been extended, a start has been made at sorting out the neurological syndromes peculiar to the area, and further advances have been made in recognising the all-too-frequent effects of protein malnutrition It seems likely that medical research in the Caribbean may pay big and rapid dividends in the future Apart from the study of specific local diseases, there is a great opportunity for the epidemiological and community-survey approach What precisely is the peculiar distribution of steatorrhœa, and is it related to diet? Is the prevalence of hypertension really as great as it seems? How does the prevalence of hypertension or diabetes compare with racially corresponding groups in Africa? What is the prevalence, class, and locality distribution of the paraplegic syndrome which figures so largely in the neurology of the Caribbean? And there are many other absorbing questions Help in the elucidation of diseases common in Britain may well come from a study of the differences they show in areas like the Caribbean

The rapid fall in death-rate caused by the elimination or reduction of the killing diseases by chemotherapy has increased population pressure in nearly every West Indian island and aggravated the problems of

In England Now

A Running Commentary by Peripatetic Correspondents

I TURNED thankfully from the chronic depressives, the neurotic necks, the itching unmentionables to the garden—to my potatoes, poking their tardy way up to the spring sunlight, the lettuces in urgent need of watering, the weed-covered borders already herbaceous to the eye of faith But I was followed by the tribe—two small girls and two small boys Eight small feet and eight small hands can undo much in a short time One of my daughters was soon hard at work pulling up lettuces She had been impressed by my transplanting efforts a few days before While I sweated pulling out innumerable weeds among the rows, I cast a friendly eye on my sons digging industriously at the other end of the patch "Let's plant them here," said one What, I wondered, was it going to be this time It soon transpired Triumphantly the seeds flew in all directions, some into the hole they had dug, many more on to the newly weeded potato patch They were dandelions

So Nature redresses the balance impious man presumes to disturb As in the surgery, so in the garden the best motto is "To watch and admire, not harm or destroy" Mrs Brown, late that evening, must have been impressed by the philosophical attitude of the doctor she had called to see her, as usual quite unnecessarily Had she known, the garden soil, still clinging to his shoes, was the clue

* * *

"I'm afraid you have the wrong number," my mother said in the determined voice of the slightly deaf I had telephoned to inquire after her health and was about to convince her of my identity, but she went on almost without pausing for breath

"Isn't it annoying the way they never take the trouble to get the right number for you? I should certainly complain to the operator if I were you My husband—I should say my late husband—always said people simply won't take the trouble these days Those operators on the telephone exchange have nothing to do but sit there and get the right numbers, but they always seem to get them wrong somehow And I expect you're a busy person, aren't you?"

Hurriedly I said, "Yes, I'm the wife of a busy doctor I haven't much time to spare"

My mother was plainly delighted "A doctor!" she exclaimed "Now isn't that strange, one of my daughters is married to a doctor She lives in Hertfordshire you do too! Well the world is a small place I wonder if you know my daughter She's next to the youngest I have five girls I did have three boys but unfortunately I lost them all Have you any children? One girl? My daughter, the one that's married to the doctor has one little girl What a strange coincidence! Actually her little girl is adopted Venetia, that's my daughter you know, lost her own baby boy but her husband thinks the world of this child He simply idolises her but then he would He's a most charming man His name is a household word here where I live You see before he married my daughter he had a practice here in the very road where I live It was the talk of the whole neighbourhood when they were married Actually they eloped Of course it was all very romantic but I can't say I was entirely pleased about it at the time After all, every mother wants to see her daughter married in white, doesn't she?"

I was about to scream into the telephone, 'Mother, how dare you tell all your business to a stranger?' when I realised it was an accusation I couldn't make and anyway I hadn't the chance She went on

'But as I said, he's the most charming man I don't know what I would do without him I certainly wouldn't ever have a night's sleep if it weren't for the tablets he gives me He's what they call Nature's gentleman, you've heard the expression haven't you?"

I mumbled something in a voice as unlike my own as possible and listened, fascinated while she continued

"Two of my other girls are married too But they are as unlike Venetia as it's possible for sisters to be Both very fair and if I may say so, pretty too Venetia isn't She's very dark I suppose she takes after my side of the family I don't mean to say she's ugly, far from it In fact only the oth day I came across a photograph of her when she was a ba lying naked on a rug kicking her chubby legs in the a I must show it to her some time Mothers aren't suppo to have favourites among their children but you can't he it When I had my duodenal ulcer, Venetia was the on one I wanted near me She was the greatest comfort to m And of course good looks aren't everything, are they m dear?"

Very hot, with a rapidly rising blood-pressure, said, 'I'm afraid I must go now" My mother was once concerned

"I'm afraid I've kept you too long I'm so sorry my dea but it's been so nice to have a chat I do hope you get yo number right next time"

I watched the clock and let a quarter of an hour sl by before I telephoned her again This time I left doubt as to my identity My mother said

"My dear, I've been thinking about you A charm girl just got on to me by mistake The operator gave her t wrong number and would you believe it, she's married to doctor and lives in Hertfordshire too I wonder if you kn her"

Overheard in Queen Square "You've passed — now you have to take the Harryplattic oath!"

thiopentone level was highest in those babies delivered at the earliest moment after maternal injection of the drug, and the level fell exponentially with an increase in the time before delivery Moreover, the maternal and fœtal serum levels of thiopentone at the time of delivery were approximately equal in every case, whatever the time between injection into the mother and the birth of the child The placenta apparently offers little or no barrier to the passage of thiopentone, and Crawford believes that the length of delivery after the induction of anæsthesia by a single small dose of thiopentone is of no significance

CAUSE OF HYPOGLYCÆMIC SYMPTOMS

Since 1924, when Cannon et al.[1] showed that insulin hypoglycæmia caused a release of adrenaline into the blood of animals, it has been generally accepted that adrenaline is largely responsible for hypoglycæmic symptoms in man The obvious difficulty in accounting for the sweating which is usually a prominent feature of hypoglycæmia, but which does not follow intravenous or intra-arterial injections of adrenaline,[2 3] could be overcome by postulating that adrenaline release was part of a general hyperactivity of the sympathetic nervous system, due to central stimulation by hypoglycæmia Though it is mediated by the sympathetic system, the innervation of sweat glands is cholinergic, and the abolition of sweating by atropine [4] and by hexamethonium [5] is compatible with this hypothesis But other explanations are not ruled out, and observations pointing to another mechanism have been accumulating Recently Weil-Malherbe,[6] using a chemical method of assay, recorded a drop in plasma-adrenaline after insulin His measurements of the normal adrenaline level are at variance with the figures reached by biological assay, and although differences in technique partly reconcile the results of the two methods, the difference of opinion on the effect of hypoglycæmia [7] remains unresolved

von Euler and Luft [8] demonstrated in man that urinary adrenaline excretion is much increased after insulin French and Kilpatrick [4] have confirmed this, and they have recently tried to elucidate the part played by adrenaline in causing the symptoms of hypoglycæmia They found that although sympathectomy prevents adrenaline release, as measured by urinary excretion, it does not significantly alter the hypoglycæmic symptoms It is hard to estimate the significance of their finding that sweating was invariable in their sympathectomised subjects, without knowing more about the methods used to assess it, for, especially as far as sweating is concerned, sympathectomy is seldom complete because there are ganglia in those rami which escape removal [9] Since peripheral nerve block, atropine, and hexamethonium stop hypoglycæmic sweating, it is hard to believe that it is not mediated by the sympathetic nervous system and that failure to abolish it is not due to the incompleteness of the sympathectomy

Chalmers and Keele,[2] having demonstrated that local injections of adrenaline cause sweating, saw no reason to challenge the concept of a solely cholinergic nerve-supply to sweat glands It is of interest that in two clinical conditions in which adrenaline release occurs—hypoglycæmia and phæochromocytoma—sweating is a prominent symptom "Too much significance," Chalmers and Keele remark, "should not be attributed to the failure of intravenous and intra-arterial adrenaline to elicit sweating our experience has been that acetylcholine and mecholyl (methacholine) may also produce little or no sweat response when given systemically The possibility that under certain conditions sweating might be caused by circulating adrenaline has not been excluded "

After the administration of insulin, there is a considerable increase in hand blood-flow in normal persons,[4] and a decrease in those with a sympathectomised upper limb whose vessels, as a result of denervation, are sensitised to adrenaline [10] This suggests that, although adrenaline is released, there are nervous influences which more than counteract its effects in normal persons Evidence for a decrease in the activity of adrenergic nerves has been produced by von Euler and Luft,[8] who found a reduction in the amount of noradrenaline in the urine in hypoglycæmia They say that the chief source of urinary noradrenaline is adrenergic nerve endings There is also the well known vagus mediated increase of gastric secretion in insulin hypoglycæmia to support the conclusion of French and Kilpatrick that "there is much evidence for a general activation of the cholinergic nerves"[4] in this condition But every nerve arising in the central nervous system and ending outside it is cholinergic, whether it passes to the neuromuscular junction, to an autonomic ganglion, or to the suprarenal gland, so this conclusion serves to underline the fact that a great deal still remains to be discovered and that it will probably have to be sought in the central nervous system itself—no easy task What does seem to be clear, however, is that "adrenaline is not the main agent in determining the clinical features of hypoglycæmia in man "

LEUCOTOMY AND THE FAMILY

Frontal leucotomy produces changes in those important but ill defined aspects of behaviour which are termed "personality " The changes may be considerable and are not always desirable [11] They were first clearly demonstrated by workers such as Rylander, who sought their evidence in the home, from friends and relatives Here the effects of leucotomy were found to be greater and more complex than was at first suggested by observation of patients in hospital It follows that the home, to which it may be hoped patients will return, and particularly the personalities of friends and near relatives—above all, wives and children—with whom they will have to live, are of the greatest importance in measuring the success or failure of the operation Nevertheless, this information is often very cursorily gathered A brief and sometimes stereotyped report from a psychiatric social worker, or an interview with the one relative thought to be mainly concerned, may be taken as sufficient, and the complex psychodynamics of the family is neglected When the patient returns home, usually largely relieved of his more prominent symptoms, the effect on the family may sometimes be disastrous

A recent detailed study [12] of 19 women who returned to family life after operation is illuminating The hazards are potentially greatest when the patient is a mother of small children, though the determination to keep a home together may be a stabilising influence Even with single women living with relatives, however, the previous social unit may break down completely Lane's inquiries [12] emphasise the overwhelming importance of the personalities of those who have to live intimately with the patient after operation Detailed information on this score must be regarded as essential before deciding on operation, and more particularly in planning postoperative care The information will also be valuable in determining what kind of preparation to give relatives before they meet the changed personality, and how much and for how long they will need help in dealing with their new situation This is one aspect of social psychiatry pudendal-block anæsthesia In all outlet forceps and most mid cavity, including occipitoposterior positions, in the absence of a contracted pelvis, and in breech deliveries this method can be used, and a high percentage of success can be achieved with but little practice The dangers of inhalation of vomit or regurgitated acid stomach contents are thus entirely avoided

The best technique for pudendal block has been described by many writers and consists of injecting 10 ml of local anæsthetic around the internal pudendal nerves in the region of the ischial spines It is essential to use a 5 inch, 20 gauge needle and inject at three points, just below the spines, in the nerve canal, and in the greater sciatic notch behind the spines in order to catch all the nerve branches No further injection is required, and the anæsthesia obtained covers a much greater area than the anatomy books would lead one to expect and lasts long enough to repair the perineum after delivery

Spinal needles are too short for this purpose, and their base is not sufficiently strong The needles I use had to be specially made since none was obtainable in London, which would suggest that this technique is not receiving the attention it deserves, and at a recent survey made among candidates at a higher examination I found that less than half had seen a pudendal block and few had performed one

There is, therefore, at present, ample opportunity of using a safe method of anæsthesia I would further suggest that all students should be taught the technique of pudendal block and all candidates for higher obstetric degrees should give evidence of having had practice in the method Experience would be obtained by using pudendal block for normal deliveries, and where the use of forceps is anticipated this will allow early application Excellent muscle relaxation is also obtained by this means, but the patient usually has to be told to push in the absence of local sensation

A qualified anæsthetist should, if possible, give the remaining anæsthetics This is particularly essential where some abnormality is present, such as prolonged labour, for cæsarean sections, or in patients who are fat and thick-set or nervous All hospitals should be able to arrange for this

Many modern methods, especially when newly introduced, as you state, can be dangerous, except in the hands of the anæsthetic specialist, and the house surgeon or anæsthetic registrar should not employ them in obstetrics For instance, thiopentone in small doses can cause laryngeal spasm and fœtal death from anoxia, and maternal death with an average dose in the presence of anæmia, a closed circuit with certain anæsthetics, and lack of facilities for lung inflation with relaxant drugs, have been seen to result in maternal and fœtal death

If the domiciliary patient cannot receive a pudendal block, or be brought into hospital, then the help of a qualified anæsthetist should be available and paid for by a domiciliary visit

These suggestions attempt to answer the questions in your annotation and will go a long way towards lessening the growing dangers of anæsthesia in hospital and domiciliary obstetrics

London W 1

D J MacRae

SIR,—The technique outlined by Dr Coleman and Dr Day is a bold attempt to solve an outstanding problem While I agree with the general principle of employing a cuffed endotracheal tube, I should like to endorse the comments in your annotation—namely, that a quicker induction is probably obtainable with 50% cyclopropane and oxygen, and that intubation should only be performed in the head up position advocated by Morton and Wylie[1] I have now seen three cases of massive regurgitation when succinylcholine was administered in the horizontal and head down positions, but no trouble has so far resulted from the head up position

A series of cases such as that described serves only as a pointer to future lines of investigation The next step is to obtain a properly controlled series of cases comparing the new technique with that of, say, nitrou oxide/oxygen/ether It could then be determined whether in fact the technique of Coleman and Day had any advantages over the older method, when both techniques were utilised by experienced anæsthetists It would become apparent whether the success of the new method was due solely to the technical facility of its originators

I further suggest that the studies should be extended to include the fœtus By a method of assessment such as that of Apgar,[2] the effects of anæsthesia on the fœtu can be compared Only in this way is it possible to obtain a thorough appreciation of such a new technique

University College Hospital,
London, W C 1

L Kaufman

SIR,—Your annotation ends with the question "Wh are students to be taught about obstetric anæsthes and how are they to be equipped to deal with a emergency in domiciliary practice?" May I diffidently suggest that the answer to this is that they should be taught to give anæsthetics? The revival of this useful but now virtually discarded branch of teaching might even result in the young doctor being able to cope with the baffling problem of providing a few minutes' anæsthesia for a healthy young mother while the forceps are put on

Windsor

Douglas Belfrage

FATS AND DISEASE

SIR,—Permit me to refer to Dr Sinclair's fascinating letter of April 7 and the article by Dr Bronte Stewart and his colleagues (April 28), both emphasising the importance of adequate content of essential fatty acid (E F A) in our diet They involve important conclusions, especially the one expressed by you in your leading article (April 28) "If these results are substantiated coronary-artery disease becomes in part a preventable disorder—but at a cost of a complete revolution in our present-day dietary habits The hydrogenation plant of our modern food industry may turn out to have contributed to the causation of a major disease" It can be concluded also that it is wrong to advertise margarine containing hardened fats as properly vitaminised

Bronte Stewart et al 's figures indicate that in a high fat diet the E F A content of fats should be above 5% if an increase in serum cholesterol is to be avoided, 15% being adequate or possibly more than adequate In the diets used, this is equal to above 6 g and below 19 g E F A per 2500 calories With eggs, however, the result is quite different, although they contain much E F A That eggs contain cholesterol may be the explanation

Shapiro and Freedman[3] showed that the hypercholesteræmic response to cholesterol feeding in rats on a sulphur-deficient protein diet was largely prevented by the use of dietary fat containing E F A A calculation based on their figures shows 16 5 g E F A per 2500 calories to be adequate

As to the "etcetera" of Dr Sinclair's letter, he refers to my letter on hardened fats and lung cancer[4] I should like to refer also to the further three letters[5] in which I tried to show that the food consumed domestically in the U K had a decreasing content of E F A If the diets included in my calculations were representative the average consumption of linoleic acid fell between 1939 and 1952 from about 5 to 3 g per head per day, and of

FLOUR

MEMORANDUM OF A CONFERENCE * APPOINTED BY THE MEDICAL RESEARCH COUNCIL TO PREPARE EVIDENCE FOR SUBMISSION TO THE GOVERNMENT PANEL ON COMPOSITION AND NUTRITIVE VALUE OF FLOUR

Nutritional Requirements

The most recent authoritative assessment of nutritional requirements in this country is contained in the report of the Committee on Nutrition of the British Medical Association published in 1950[1]. The nutritional levels recommended in the report were formulated not only on the results of research but also on the general basis that a high standard of health had been maintained on the diet prevailing in Great Britain during the war and that the nutrient content provided by that diet might reasonably be accepted as a satisfactory standard for the population as a whole. The B.M.A. recommendations take account within broad limits, of differences of age, sex and physical activity, and allow a margin for individual variation. With the reservation that the number of people in the community whose requirements may be significantly different is unknown, the council's conference are agreed that the B.M.A. recommendations are a fair assessment of average requirements with a reasonable, and not excessive, margin of safety; that in the absence of other evidence they represent a level to which it is reasonable to expect the diets of all to attain; and that they should be used as the standard in considering the effects of any changes in the national diet.

Food Consumption in Relation to Nutritional Requirements

The National Food Survey Committee of the Ministry of Agriculture, Fisheries and Food conducts an annual survey of the domestic food consumption and expenditure (allowance being made for meals eaten outside the home) of a randomly selected sample of households (over 11,000 in 1954) in some sixty parliamentary constituencies throughout Great Britain. In addition to the figures for 1952 which have been published,[2] those for 1953[3] and 1954 have been made available by the Ministry to the council's conference. Table I is taken from the findings of the survey and shows for certain selected nutrients the extent to which the B.M.A. requirements were met in these years. During this period average expenditure on food was rising, and, with the gradual end of rationing, a wider variety of foods was becoming available; while even after the decontrol of flour in August 1953 the bread consumed continued to be made almost entirely from National flour which was required under the Flour Order 1953 to be of 80% extraction or its equivalent. Table I shows that the B.M.A. standards were in general being met, but the figures also suggest that, on the average, large families, and particularly those with adolescents as well as children, were in some respects barely meeting them, although they were not falling short to any substantial degree. The classification of households given in table I does not, however, distinguish between different income groups and may therefore to some extent obscure conditions in the families in the lowest income group. Reliable information on these, the least favoured families cannot be obtained from the survey because the sample is too small, but the Ministry has been asked to prepare figures for food consumption in families with four or more children in the two lowest income groups, which taken together represent about 30% of the total number of such households and will provide a sample large enough to give valid results. The analysis when completed will be considered by the conference and forwarded to the Panel.†

Contribution of Bread and Flour to Nutritional Requirements

In this country bread is the largest and most important single item of the diet, providing between one fifth and one-third of the calories and protein and a high proportion of other essential nutrients (table II). It can therefore be expected that a reduction in the extraction-rate of flour will affect the intake of nutrients, and particularly so in the largest families which are most dependent on bread. Table III shows the concentrations at different extraction rates of some of the nutrients present in flour, and it will be seen that there are some significant differences between 80% and 70% extraction flours. From the figures in table I it is evident that a change in extraction-rate from 80% to 70% would entail a less favourable nutritional standard, particularly for the most vulnerable groups.

Nutrient Content of Flour and Fortification

A reduction in the extraction-rate of flour affects the levels not only of vitamin B_1, riboflavine, nicotinic acid,

* The figures in this table are derived from the findings of the National Food Survey. The contribution of bread and flour to the diets in these households is calculated on the basis of the mean figures for the composition of flour at different extraction-rates which were obtained from the Ministry of Agriculture, Fisheries and Food and which are given in table III. The flour normally used during these years was National flour which was required under the Flour Order 1953 to be of 80% extraction or its equivalent. The figures for 70% extraction have been included for comparison.

† Provisional figures only.

anæsthetics Whilst I myself am convinced of the greater safety of the extradural nerve block, I fully realise that sometimes a spinal may be either the only possible method or the method of choice In such a case, where the anæsthetist believes that the possible complications of the method are outweighed by the probable ill effects of not using it, he should have the backing of his colleagues

London S W 15 G C STEEL

MEDICINES FOR HOSPITAL OUTPATIENTS

SIR,—Dr Tuckman's letter (May 26) calls attention to an aspect of the health service which has rightly received much publicity in recent months—namely, extravagance in prescribing There are, however, one or two points with which I cannot agree

The normal procedure in hospitals is to supply medicines on a time basis—usually a sufficient quantity to last the patient until the next visit to the outpatient department, though in the case of a patient returning for treatment to his general practitioner it is usual to supply medicine for one week only Generally speaking, the issue of antibiotics to outpatients is very carefully controlled, and I doubt very much whether a similar control can be said to exist with regard to prescriptions issued by general practitioners

ORAL STREPTOMYCIN IN BACILLARY DYSENTERY

SIR,—I was interested to read Dr Sangster's article (May 19), showing that oral streptomycin is an effective treatment for sonne dysentery

During the last three months of 1955 there was an epidemic of Sonne dysentery in this village, in which fifteen families were involved, with 43 individuals with positive stools

Of these 43, (*a*) 11 were cases of diarrhœa seen by me in an attack, (*b*) 12 gave a history of previous mild diarrhœa to the school medical officer investigating the epidemic, and (c) 20 were symptomless carriers, detected when the families of (*a*) and (*b*) had their stools examined 38 of the 43 with positive stools were school children or children under school age

Early in the epidemic an organism isolated from one of the cases was reported as having the following sensitivity reactions in vitro sensitive to streptomycin, chloramphenicol, oxytetracycline, sulphadimidine, phthalylsulphathiazole, partially sensitive to sulphanilamide and sulphaguanidine, resistant to penicillin, aureomycin, erythromycin, succinyl sulphathiazole

It therefore seemed reasonable to give every case a five day course of phthalylsulphathiazole, of which stocks were held in the dispensary, in the first instance And it was decided, after consultation with the M O H of the rural district, to give patients whose fæces remained positive after this treatment a course of oral streptomycin In the event plain oral streptomycin was not obtainable locally, and Guanimycin' (Allen & Hanburys) was used This preparation contains streptomycin 0 25 g and sulphaguanidine 2 g per fluid ounce The doses given were as follows

Adults —Phthalylsulphathiazole 0 75 g q i d , guanimycin 1 ounce four hourly to a total of 8 ounces

Children over 3 —Phthalylsulphathiazole 0 5 g q i d , guanimycin ½ ounce four-hourly to a total of 4 ounces

Children under 3 —Phthalylsulphathiazole 0 25 g q i d guanimycin 2 drachms four hourly to a total of 2 ounces

Of the 42 patients with positive stools who were given phthalylsulphathiazole 32 remained positive after the course —a failure rate of just over 75% These 32 were then given a course of guanimycin with the following results

Time (weeks) to become negative *

Under 1	*1–2*	*2–3*	*3–4*	*4–5*	*5–6*	*6–7*	*7–8*	*8–9*
20	2	0	1	1	2	3	2	1

* Until the first of three consecutive negative stools

Of the 32 cases, 20 became negative in less than one week and a further 2 during the second week, representing a failure rate of a little over 30% Of the 10 cases remaining positive after this treatment 7 came from two families who had had clinical dysentery of moderate severity, and the impression was that reinfection was occurring after clearance (The effect of a repeat course of guanimycin given simultaneously to all the household was not tried)

The question remains, of course, as to which of the two constituents of guanimycin was responsible for the improved result It seems reasonable to suppose that it was the streptomycin, because (1) the organism was reported as being sensitive to streptomycin in vitro, but only partially sensitive to sulphaguanidine, (2) the cases had not cleared after phthalylsulphathiazole, which is said to be more effective than sulphaguanidine in this disease, and which was given for a longer period

Parliament

Medical Problems on the Roads

ON the report stage of the Road Traffic Bill in the House of Commons on May 31, Mr GODFREY NICHOLSON moved a new clause to give the Minister power to prescribe definite specifications for crash-helmets and to make their use compulsory for people riding or being carried on motor-cycles Mr HAROLD WATKINSON, Minister of Transport, said that he could not accept a mandatory clause imposing on him the duty of making the failure to wear crash-helmets illegal The police advised him that it would not be possible to enforce this Casualties involving motor-cyclists were 22% higher in 1955 than in 1954 He was impressed with the need to do something about these severe casualties, and if the clause were withdrawn he promised to consider whether a clause could be introduced when the Bill reached the House of Lords to give the Minister permissive powers enabling him, if the voluntary use of crash-helmets did not improve at a satisfactory rate, to make regulations so that the wearing of crash-helmets became obligatory Any clause which the Government introduced would cover both wearing and standards Mr Nicholson withdrew the new clause

Mr RONALD BELL moved a new clause providing that diesel vehicles should not be used on any public road in the Metropolitan police district He was sure that fumes from traffic played a large part in causing respiratory diseases among people in London The number of non smokers who died of cancer of the lung was nearly ten times as high in the cities as it was in the country There could be little doubt that in one way or another that was due to atmospheric pollution The council of the British Medical Association had called the Minister of Transport's attention to the possible dangers of diesel fumes and had stated that they viewed with alarm the proposal to replace electric trolley buses by diesel engined buses The Minister had replied that he could not hold up the normal commercial development of road vehicles without more definite information as to its effect on public health than was at present available Mr Bell suggested that it was for London Transport and the Minister to show that this change would not be harmful to the health of Londoners Mr MOLSON, parliamentary secretary to the Ministry, said a revolutionary clause such as that proposed by Mr Bell could be accepted by the Government only if a case for it were fully made out The effect of diesel fumes was being investigated by the Fuel Research Station and the Medical Research Council So far there was no evidence that exhaust fumes from diesel-driven vehicles had any measurable effect on the health of those who breathed them Unless and until research was able to establish the need for something like this clause the Government could not accept the proposal The clause was by leave withdrawn

Safety, Health, and Welfare in Agriculture

On the motion for the third reading in the House of Commons on May 29 of the Agriculture (Safety, Health and Welfare Provisions) Bill, Mr HEATHCOAT AMORY the Minister in charge of the measure, said that the alterations made in the Bill during the discussions had protein, that these undernourished children should have shown a greatly increased growth-rate that was not dependent on the rate of extraction of the flour. It is also to be noted (see table III) that the 70% extraction flour used in the feeding trial in Germany was rich in some nutrients and indeed, on the analyses available, in some respects more nearly resembled the 80% than the 70% flour used for breadmaking in this country.

These considerations are of importance in assessing the relevance of the results of the trial to conditions likely to obtain in this country. The conference agree with the first conclusion drawn by Dr Widdowson and Professor McCance on p. 68 of their report, which emphasises that caution should be exercised in generalising from results obtained in one experimental setting.

The Effects on Health

The conference do not suggest that a reduction of the extraction rate of flour from 80% to 70% would in itself be likely to give rise to widespread illness in the present favourable circumstances in this country. If, however, for any reason the population had to rely on bread for a greater proportion of their nutritional requirements than they do today, the different nutrient content of breads made from flours of different extraction rates might become important, particularly in the more vulnerable groups. Moreover, the absence of recognisable illness in an individual is not a sufficient criterion that his diet is nutritionally sound. An iron deficiency, for example, invariably affects efficiency; yet the resulting anæmias may vary in intensity from those detectable only by laboratory tests to others which are completely incapacitating. Again, a person may live for long periods on a diet supplying marginal amounts of vitamin B_1 without suffering from beriberi, and then under some additional stress collapse with fulminating beriberi. Great caution is therefore needed before making changes which may lower the nutritional value of a nation's staple food.

Conclusions

The conference therefore conclude that in the light of present scientific and medical evidence:

1. Flour of 80% extraction is a more complete source of nutrients than unfortified or partially fortified flours of lower extraction rates.
2. On the evidence available at present, there are families which, with bread made from unfortified 70% extraction flour, would not be obtaining all their nutritional requirements in full, as recommended by the British Medical Association Committee on Nutrition in 1950.
3. The consumption of a 70% extraction flour, even if this is partially fortified, would lead to a reduced intake of some nutrients. Although such a reduction would not necessarily lead to an increase in recognisable illness, it would, in the present state of knowledge, constitute a risk which can be avoided.

INVALID HOISTS AND SIMILAR NURSING AIDS

H. R. Rishworth

C.B.E., V.D., F.R.C.S., D.P.H.

Increasing attention is being paid to mechanical aids to lighten the labour of nursing helpless patients. The present shortage of nurses may be a cause but there are other factors at work.

The tendency to manipulate the body as a whole and in one unit in spinal conditions and in affections of the major joints, demands an increase in the effort necessary on the part not only of the nurse but also the patient.

Injuries of the spine now receive care to an extent which nurses probably did not experience before the world wars.

Patients with severe paralytic poliomyelitis who in past years might not have survived, can today, after careful nursing and attention to the respiration and skin, attain in the course of a year or two a considerable measure of happiness and comfort if regularly assisted each day from bed to chair, commode, or bath and back to bed—a manœuvre which has aptly been described as "bridging the gap" (Vinden and Bayne 1955).

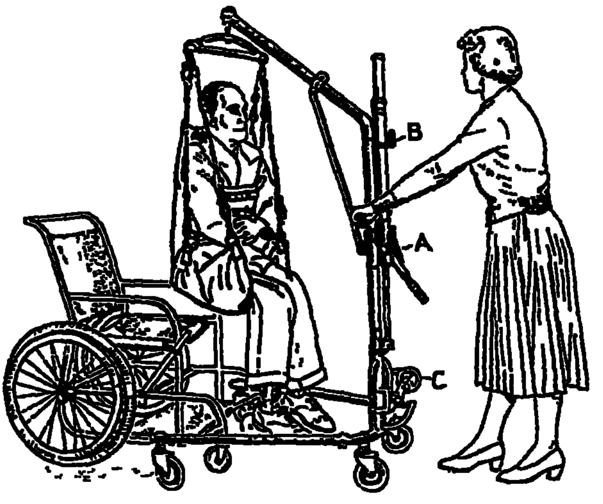

Fig. 1—'Easicarri' hydraulic hoist: A, hydraulic lift handle; B, hydraulic release valve; C, wheel for opening and closing base.

Aged patients receive more scrupulous and exacting attention; indeed longer survival into increasing helplessness of many old people is certainly a factor in directing attention to mechanical devices. In many cases, especially in patients above normal weight, efficient movement and turning are almost impossible without some mechanical aid or a great deal of labour on the part of several assistants.

Some Apparatus in Use

Russell and Schuster (1956) describe several devices developed by them and in use at Headington Hill Hall Rehabilitation Centre, Oxford: one is a modification of the mobile 'Sherpa' industrial truck; two others are types of crane fixed either to the wall or to the head of the bed. Two of the three are operated hydraulically and the third by a counterpoise arrangement of weights.

The Huddleston hoist (*Nursing Mirror* 1954), manufactured by John Bell & Croyden, 50, Wigmore Street, London, W.1, is of duralumin and makes it possible for a nurse to deal single-handed with a bedridden patient. The whole apparatus can be transported and assembled at the bedside without special tools.

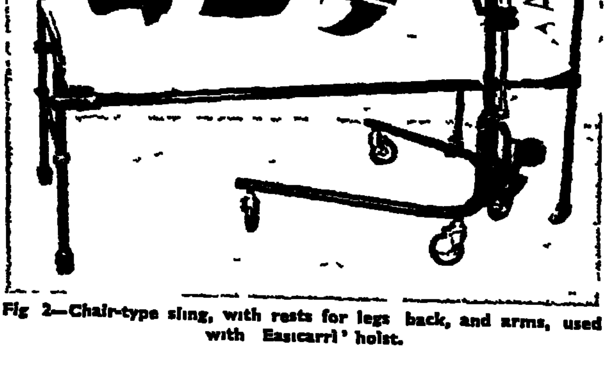

Fig. 2—Chair-type sling, with rests for legs, back, and arms, used with 'Easicarri' hoist.

feature, have had a remarkably fertilising effect on many aspects of health work in European countries The withdrawal of the Eastern European countries from W H O was a matter of deep regret to Begg He knew from his own earlier work in Poland how much both W H O and the countries which withdrew had to gain by continued participation He was always confident that in time the 'inactive members" would return, and he did everything he could to prevent anything being said or done on either side which would make that impossible It is tragic that he should have died when negotiations are taking place which make likely the early return of the Eastern European countries to active work with W H O

A D writes "Norman Begg was one of several Aberdonians who were prominent in the L C C fever service One of them, Andrew Topping, who always had the highest regard for Begg's ability, urged me to second Begg for work in Poland I recall that when an extension of his secondment was under consideration Dr Martha Eliot of the Children's Bureau, Washington, who had just returned from a visit to Poland, told me that Begg had more influence in Warsaw than any other person from the Western countries His work for UNRRA and W H O brought him into contact with a host of people of many nationalities He was genial, friendly, and highly esteemed by all with whom he had official relationship, including his own office staff, who were devoted to him"

"Bright blue eyes and a dark complexion," writes an ex-colleague, "gave Norman Begg a striking and handsome appearance As he listened in silent scrutiny one s lucid exposition began to seem—what it so often was—mere incoherent and irrelevant babbling Many of his colleagues found this daunting, but all recognised the value of his work and his ability as an epidemiologist and medical administrator In the treacherous cross-currents of post-war Warsaw, Begg s obvious competence, impartiality, reticence, and persistence earned the respect of all the warring interests Later, as the first director of W H O's European regional office, he began a long struggle to remove the office from Geneva, where—in his view—it was too much overshadowed by headquarters, and to give it a physically independent existence The decision last year to move it to Copenhagen was in part a tribute to his success as its director and must have given him great satisfaction"

G R H writes "Norman Begg had a combination of qualities which is unusual, especially in a physician He was an excellent administrator and at the same time a man keenly interested in scientific developments relevant to medicine As an administrator he was completely free from the faults of the bureaucrat, and his wide interest in scientific developments always carried with it the practical question 'What may the development of this knowledge one day make possible for public health practice?' When he was appointed to his important international post he was young and comparatively unknown in public-health circles in his own country Many doubts were expressed when he was chosen, but not by those who knew him He filled it with great distinction He had an extraordinary combination of far-seeing vision, quiet unruffled administrative efficiency, and deep modesty He had no idea what a remarkable man he was and that he was making a greater contribution to European unity than any politician His early death is a serious setback for international health work in Europe It is a personal loss to those who knew him and worked with him"

ELEANOR JOYCE PARTRIDGE

F R C S

Dr Joyce Partridge, who died on May 11 in Switzerland, was born in Devon in 1893 and was educated at Bedford High School She studied medicine at the Royal Free Hospital, qualifying in 1917 After holding posts at the Royal Free Hospital and the Elizabeth Garrett Anderson Hospital she took the F R C S in 1921 Later she went into general practice, and her growing realisation that many of her patients needed more than medicine and surgery to get them well led her to study psychology and especially the methods of C G Jung She joined the staff of the Tavistock Clinic, and became a member the Society of Analytical Psychology Shortly before late war she moved to Devon and began to practise psychiatrist in Exeter Later she combined her con sultant practice with the medical directorship of stone Grange Nursing-home and the appointment visiting psychiatrist to Withymead Centre at

E A N writes "Joyce Partridge was a very person first and a psychiatrist second I had known as a friend and colleague for close on eleven years, and during that time I had come to see something of wisdom and calmness which she brought to her work She was never hurried and she gave of her best to patients striving at all times to make them feel that were worthwhile people Perhaps one of the things remember best about her was her insistence on rhythm of life She felt strongly that in this world rush there must be real times of relaxation to balance the periods of stress and work The problem of death was problem to her When the apple was ripe it fell Those of us who knew her and mourn her loss know that would have felt that there was a rightness about death, and in her own words, 'It was just part of God pattern'"

She is survived by her husband, Mr Edward Wenham whom she married in 1931, and by one daughter

JOHN CHRISTOPHER EYRE PESHALL

M A Camb, M R C S

Dr Peshall, who died on May 30, at the age of was the only son of the Rev C J E Peshall, D S O a former archdeacon of the Fleet He was educated at Stowe, Trinity College, Cambridge, and St Thomas's Hospital After qualifying in 1944 he went as medical office on an expedition to Antarctica, and on his return was for a time one of the resident medical officers at the General Lying-in Hospital, York Road, London He was also a surgeon lieut-commander in the R N V R In 1952 he joined a general practice in Bermondsey and recently he had taken over the editorship of the gazette of the South London faculty of the College of General Practitioners

W B M, one of his partners, writes "Chris Peshall entered into the busy round of medical work with boundless zest and energy He was particularly interested in geriatrics and took endless trouble in helping many elderly folk, often taking them out in his car while on his rounds The secret of his happy life was a simple faith in God which reflected itself in all his doings"

Dr Peshall leaves a widow and two young sons

USE OF HOSPITAL RECORDS IN RESEARCH

At a meeting of the medical section of the Royal Statistical Society in London on May 29 the use of routine hospital records in research was discussed

Dr A C **Dornhorst** dealt with the nature of clinical records The history was neither a statement of fact nor a record of what the patient said It was rather an aide memoire, a personal document to remind the writer of an interview at which the patient's statements were largely determined by the nature of the questions asked and the manner of their asking It was the record of a conspiracy between the patient and the doctor and was subject not only to errors of memory and reporting but also to the moods and current ideas of the reporter The observer error in recording physical signs and radiographic appearances, and the experimental error of laboratory estimations, were becoming increasingly well known It was an interesting paradox that, despite all these difficulties and inconsistencies, there was in general little difference in the conclusions reached from them The physician did not, in fact, arrive at his diagnosis by logical inference from what he recorded Clinical records tended to become shorter as the writer grew older, and with increasing experience fewer words were required to remind him of his attitude of mind at the time the record was made Research from routine records might be worth while, but it would be interesting to inquire further into what such records really were

Dr J R **Bignall** said that routine hospital records could give valid answers only if they were asked the right questions Every question must be put in such a form that it was nowhere assumed that what was recorded in the notes was true Each part of the question should then be examined to estimate the probability that the recorded statement was a statement of fact Only by having an intimate knowledge of the special subject of the study was it possible to estimate these degrees of reliability and hence to make valid inferences Much research from hospital records used comparisons, and in these the effect of inaccurate reports might be cautiously neglected, if it could be reasonably assumed that the reliability of particular statements in the questions asked was not influenced by the nature of the characteristics being compared Much research from routine records was undoubtedly a waste of time But properly conducted it could be as logically correct and as useful as research in the laboratory

Mr M P **Curwen** said that research included not only the answering of precisely formulated questions but also the observation and reflection that necessarily preceded the making of such questions It was for this purpose that routine hospital records were most useful The precise question might be answerable only by planned prospective surveys, but retrospective study of hospital records, however inaccurate, usually determined what questions were to be asked There were some statistical difficulties associated with such studies For instance, in general there was no justification for using tests of significance with the type of material obtained from routine hospital records This was especially so where arbitrary classifications of symptoms, signs, and pathological reports were being used, for slight changes in the arbitrary groupings might radically affect the interpretation of such tests The tests were useful as rough guides to the investigator in judging whether the inferences he was drawing were reasonable, but they should not be relied on too much, nor should they usually be published in the final report

GENERAL MEDICAL COUNCIL

SESSION MAY 29–JUNE 1

There were a number of new faces at the General Medical Council on May 29, for elections and changes in Crown and university appointments have brought about an extensive alteration of composition The meeting was the last to be attended by dentists representing the Dental Board, which, as Sir **David Campbell**, the council's president, said in his address (reported last week), is to be replaced by the General Dental Council in July

The President, in bidding farewell to the dental members, said that they had been colleagues in one of the most difficult tasks which the council had had to perform, for in considering dental disciplinary cases the council was not in a position to hear the evidence but could accept the recommendation of the Dental Board or send the case back

Sir **Wilfrid Fish** replied that they had always realised the enormous value they had received from the council, he was sure that this had not been appreciated by the public as much as it should have been The dental profession, he remarked, must have gone through the whole gamut of emotions during the eighty-eight years it had been associated with the General Medical Council Sir Wilfrid declared that one of the greatest sources of pride to the dental profession was that its tradition was based on that of medicine Then, as time went on, they had had another emotion—that of frustration—to a certain extent Now independence rid them of the feeling of inferiority which was inevitable when under the tutelage of some other body

THE CAMBRIDGE LONG VACATION

In his report on the Cambridge medical school for 1954–55, Sir Lionel Whitby, the regius professor of physic, mentions that the facilities offered to medical undergraduates during the long vacation now cover not only the preclinical and transitional periods of study "but also provide unique opportunities for continuing a general education in the arts" The faculty of modern languages gives elementary courses of 24 lectures in German, Russian, French, and Italian, designed to give science and medical students a working knowledge of the language, and also more advanced courses Similarly, the faculty of English arranges for students in scientific faculties a special series of lectures in English literature and poetry In both faculties the courses are open without fee to all medical students in residence

A NEW INDIAN HOSPITAL JOURNAL

The second issue of the *Journal of the J J Group of Hospitals and Grant Medical College* appeared in April It is to be published quarterly and papers should be submitted to the hon secretary of the journal, J J Hospital, Byculla, Bombay, 8 The editor is Dr J G Parekh

---

University of Cambridge

On May 26 the degree of M B was conferred on D J Blomley and (by proxy) on R B Bennet

University of London

Dr W S Peart, senior lecturer at St Mary's Hospital Medical School, has been appointed to the university chair of medicine at the school

Dr Peart graduated M B with honours from St Mary's in 1945 and took the M R C P the following year With a Medical Research Council studentship he was attached to the department of physical chemistry at St Mary's Later he was appointed junior lecturer in the medical unit there and last year he became senior lecturer He has published papers on splenic sympathin, phæochromocytoma, and hypertensin

University of Liverpool

Mr I W MacPhee has been appointed to a senior lectureship in the department of surgery

Queen's University, Belfast

Sir Frank Montgomery, F F R, has been appointed pro chancellor of the university Dr K W Newell has been appointed lecturer in preventive medicine and Dr W H T Shepherd part time lecturer in radiology

University of Western Australia

The following appointments to chairs in the newly established medical school of this university are announced

Dr D C Sinclair university demonstrator in human anatomy in the University of Oxford, to the chair of anatomy Dr E G Saint director of the clinical research unit in the Royal Perth Hospital, Western Australia, formerly of the staff of the department of industrial health King's College, Newcastle upon Tyne (medicine), Mr N F Stanley, D SC director of the institute of epidemiology and preventive medicine and director of microbiology, Prince Henry Hospital Adelaide (microbiology) Mr Gordon King F R C S F R C O G at present professor of obstetrics and gynæcology in the University of Hong Kong (obstetrics and gynæcology) - Mr C W D Lewis F R C S senior assistant and senior lecturer in the surgical unit Welsh National School of Medicine (surgery)

Royal College of Surgeons of England

A limited number of tickets (£2 10s) for the Buckston Browne dinner on July 11 will be available to fellows and members Applications should be sent immediately to Mr W F Davis, deputy secretary of the college, Lincoln's Inn Fields, London, W C 2

Ryle Memorial Prize

The Medical Association for the Prevention of War is offering a prize (£75) for an essay from a doctor or medical student on a World Approach to Human Survival and Health Further particulars were given in Dr Glaister's letter in our columns (*Lancet*, April 21, 1956, p 509)

United Kingdom Committee for Poliomyelitis

At a meeting held at the Royal College of Physicians of London, representatives of medical and lay organisations agreed to found this committee with the object of ' contributing to the study of all the problems arising from poliomyelitis and especially those relating to its prevention and treatment ' Sir Russell Brain P R C P was elected chairman of the committee and Dr W Ritchie Russell, hon secretary

Research into Ageing

The Ciba Foundation is offering five awards (£300 each) for papers on research " relevant to basic problems of ageing" Entries should reach Dr G E W Wolstenholme, 41, Portland Place, London, W 1, not later than Jan 31, 1957

International Congress of Internal Medicine

This year the International Society of Internal Medicine will hold their congress at Madrid from Sept 19 to 23, under the presidency of Prof C Jiménez Diaz The programme includes discussions on the present situation of internal medicine, the rôle of the adrenals in the pathogenesis and evolution of internal diseases, and bronchial asthma and emphysema The address of the secretariat is Hortaleza Madrid

Medical Golfing Society

At the summer meeting of this society, held at Swinley Forest, the *Lancet* cup (scratch medal) was won by Mr R H Maudsley (6) with a score of 74

CORRIGENDUM *Aldosterone*—The initials of Dr Ivor H Mills were given incorrectly in the letter by Dr Garrod and his colleagues last week

postponed in respect of convictions in 1953 and 1954 under the Dangerous Drugs Regulations, 1937, and the Dangerous Drugs Act, 1951

In view of the satisfactory information concerning the doctor's conduct the committee did not direct the Registrar to erase his name from the Register

BREACH OF THE PEACE

Robert Lindsay, registered as of 8, St Ninian Drive, Inverness, M B Glasg (1945), appeared for postponed judgment following convictions for a breach of the peace in 1951, 1952, and 1955, and one of being found drunk in 1954 Judgment was postponed for a further year

OFFENCES ASSOCIATED WITH ALCOHOL

Last May the committee was not satisfied that the evidence concerning the habits and conduct of *Patrick Joseph Conlin*, registered as c/o Barclays Bank Ltd, Dudley, Worc, M B N U I (1920), were such as to justify them discharging the case at that time He had been convicted in 1950 of being under the influence of drink so as to be incapable of having proper control of a motor vehicle The Registrar was now not directed to erase Dr Conlin's name

Joseph John McMenemy, registered as of Burnside, Bargeddie, Glasgow, L A H Dubl (1947), was found to have been convicted at the Sheriff Court at Airdrie in 1954 of being in charge of a motor vehicle when under the influence of drink, when he was fined £15 and disqualified for twelve months, and at York City Magistrates' Courts in November, 1955, of driving a motor car when under the influence of drink, when he was sentenced to three months' imprisonment, ordered to pay £3 3*s* doctor's fees and £5 3*s* 11*d* witnesses' fees, and disqualified for three years The committee postponed judgment for a year

Andrew Francis Amerherst Gallen, registered as of 20, Orchard Drive, Giffnock, M B Glasg (1932), had been convicted at the Glasgow Sheriff Court in 1954 and 1956 of driving a motor vehicle when under the influence of drink or drugs On the first occasion he was fined £15 with an alternative of sixty days' imprisonment, and was disqualified for a year On the second the fine was £30 with three months' imprisonment as the alternative, and the disqualification was for two years Judgment was postponed for a year

BIRTHDAY HONOURS

The list of honours published on May 31 contains the names of the following members of the medical profession

Baron

Sir Henry Cohen, M D Lpool, F R C P, J P
Professor of medicine in the University of Liverpool, for services to medicine

Knights Bachelor

Samuel Phillips Bedson, M D Durh, F R C.P, F.R S
Professor emeritus of bacteriology in the University of London

Joseph Welsh Park Harkness, C M G, O B E, M B Glasg
Medical adviser to the Comptroller for Development and Welfare in the West Indies

Arthur Massey, C B E, M D Leeds
Chief medical officer, Ministry of Pensions and National Insurance

James William Tudor Thomas, M D Wales, F.R C S
Ophthalmic surgeon, United Cardiff Hospitals

C B (Military)

Air Vice Marshal Reginald Horace Stanbridge, O B E, M.R C S, R A F retd

C M G

Theodore Farnworth Anderson, O B E, M D Camb
Director of medical services, Kenya

Edward George Sayers, M B N Z, F R C P
Senior visiting physician, Auckland Hospital, for public services

Kenneth William Starr, O B E, E D, M S Melb, F.R C S
Councillor of the Royal Australasian College of Surgeons, for services to the medical profession

C V O

Francis Galloway Leslie, B A Camb, M R C S
Physician in ordinary to H R H the Princess Royal

C B E (Civil)

William Donald Wykeham Brooks, D M Oxfd, F.R C P
Consulting physician to the Royal Navy, physician to St Mary's Hospital, London

Patrick Wimberley Dill Russell, M R C S
Director of medical services, Cyprus

George Matthew Fyfe, M B Aberd, F.R C P E
Medical officer of health for Fife

Philip D'Arcy Hart, M D Camb, F R C P
Director, tuberculosis research unit, Medical Research Council

James Peter Speid Jamieson, M D Edin, F R A C S
Formerly medical superintendent, General Hospital, Nelson, New Zealand

Hallam Grey Massiah, M D
For public services in Barbados

Graeme Mitchell Mill Menzies, M B Aberd
Deputy chief medical adviser, federal government, Federation of Nigeria

Leonard James Ternouth Pellew, M B Adelaide, F R C S, F R A C S
For services to the Fire Brigade and other services in the State of South Australia

Hugh Stannus Stannus, M D Lond, F.R C P
Medical officer, Board of Inland Revenue

Frank Edward Tylecote, M D Manc, F R C P
Chairman, public health committee, Association of Municipal Corporations, professor emeritus of medicine, University of Manchester

Robert Bruce Wallace, D S O, M C, M B Glasg
For medical services in Kedah, Federation of Malaya

Frank Clare Wilkinson, M D Lpool, F D S R C S
Director of Eastman Dental Hospital and dean of Institute of Dental Surgery, University of London

O B E (Military)

Wing Commander John Nigel Carlyle Cooke, M D Lond, R A F

Colonel John Matthew Dwyer, E D, M B Adelaide, R A A M C

Major Maurice Francis Ronayne, M B E, M B N U I, R A M C, T A

Lieut Colonel Ernest Albert Smyth, M B Dubl, M CH ORTH Lpool, F R C S, R A M C

Lieut Colonel John Joseph Sullivan, M B, R A M C

O B E (Civil)

Edward Armstrong, M D Belf
Senior medical officer, ministry of health and local government, Northern Ireland

Thillaiampalm Balasingham, L.M S
Senior lecturer in pathology, University of Malaya

Enid Constance Evans, M R C S
Senior medical officer, H M Treasury

Horace Primrose Smith Gillette, M B Edin
Superintendent medical officer (specialist) malariologist, Trinidad

James Kellock Hunter, M B Glasg
Deputy director of medical services, Uganda

William Charles Donald Lovett, M D Lond
Senior medical officer, Somaliland

Cyril John Aloysius O'Kelly, F R C S I
Lately surgeon at the Royal Hospital, Basra

Albert John Orchard, M B Edin
Medical practitioner in Christchurch N Z for over 50 years

Cyril Seymour Coode Prance, M B Lond, J P
Commissioner, St John Ambulance Brigade for Plymouth, South West Devon, and East Cornwall

Alexander Noble Roxburgh, M B Edin, F R C S E
Consultant surgeon, Scottish Northern Regional Hospital Board

Anthony Andrew Russo, L R C P I
For medical and public services in Gibraltar

Charles Ernest Salt, M B Birm, J P
For public services in Denbighshire

Hope Trant, M B E, M D Dubl
Medical research officer, East African Medical Survey and Research Institute

Vera Cecil Veitch, M B Edin
Deputy principal school medical officer, Stoke on Trent

Though not definable in precise terms, scientific value can as a rule be reliably assessed Its appraisal is required and depended upon every day in the process of advancing and disseminating science Referees consulted by journals have to judge whether the scientific interest of a contribution would justify the expense of its publication Others have to decide whether the award of a research grant is worth while Scientists must be able to recognise what is manifestly trivial, just as what is manifestly false When the distinguished German physicist Friedrich Kohlrausch (1840-1910) declared, in a discussion about the aims of natural science, that he would be pleased to determine accurately the speed of water running through the gutter, he was talking utter nonsense He made no false statement of fact, but he completely misjudged the *nature of scientific value*, *for the accuracy of an* observation does not in itself make it valuable to science

The foolish promise made by Kohlrausch was of course not his true intention He was merely expounding a false theory of science more consistently than is usual relying on it, no doubt, that the errors of philosophy are only ridiculous and its extravagances do not influence our lives[2] But in doing so he demonstrated involuntarily that such absurd conclusions can be avoided—without inconsistency—only by abandoning altogether the ideal of a strictly objective science

To this revision of our scientific ideal we may find a clue in Kepler's title *Harmonices of the World* It suggests that we should acknowledge our capacity for recognising scientific value by our sense of harmony—by our emotional response to the intellectual beauty of science And since no part of science can be said to be beautiful unless it is also believed to be true, we must claim for this emotional response also that it makes contact with reality A discovery is beautiful if it reveals a new vision of reality This is the news to which the scientist's heart goes out this the object of his scientific passion

Discovery reveals new knowledge, but the new vision which accompanies it is not knowledge It is *less* than knowledge, for it is a guess , but it is *more* than knowledge, for it is a foreknowledge of things yet unknown and at present perhaps even inconceivable Our vision of the general nature of things is our guide for the interpretation of all future experience

Such guidance is indispensable Theories of the scientific method which try to explain the establishment of scientific truth by any purely objective procedure are doomed to failure Any process of inquiry unguided by intellectual passions would inevitably spread out into a desert of trivialities Our vision of reality, to which our sense of scientific beauty responds, must suggest to us the kind of questions that it should be reasonable and interesting to explore It should recommend the kind of conceptions and empirical relations that are intrinsically plausible and which should therefore be upheld, even when some evidence seems to contradict them , and tell us also, on the other hand, what empirical connections to reject as specious, even though there is evidence for them and we may as yet be unable to account for this evidence on any other assumptions

In fact, without a scale of interest and plausibility based on a vision of reality nothing can be discovered that is of value to science , and only our sense of scientific beauty, responding to *the* evidence *of our senses*, can evoke this vision Such is the *selective* function of scientific passion

This function is continuous with another, coming out clearly in the part of Kepler's text which precedes the words I quoted before He writes there

> "What I prophesied two and twenty years ago, as soon as I discovered the five solids among the heavenly orbits—what I firmly believed long before I had seen Ptolemy's Harmonics—what I had promised my friends in the title of this fifth book, which I named before I was sure of my discovery—what sixteen years ago I urged to be sought—*that for which I have* devoted the best part of my life to astronomical contemplations, for which I joined Tycho Brahe at last I have brought it to light, and recognised its truth beyond all my hopes So now since eighteen months ago the dawn, three months ago the proper light of day, and *indeed a very few days ago the* pure Sun itself of the most marvellous contemplation has shone forth—nothing holds me , I will indulge my sacred fury "

It is clear from this that intellectual passions not merely affirm the existence of harmonies which foreshadow an indeterminate range of future discoveries, but that they can also evoke intimations of specific discoveries and sustain their persistent pursuit through years of labour The appreciation of scientific value merges here into the capacity for discovering it , even as the artist's sensibility merges into his creative powers Such is the *heuristic* function of scientific passion

But the words of Kepler show us also that this truth bearing passion is far from infallible Kepler rejoiced in his discovery of the five solids among the heavenly orbits , he thought that the solar distances of the six planets known to him corresponded to the sizes of the successive Platonic bodies, as measured by the radii of inscribed and circumscribed spheres This is nonsense, and we would regard it as nonsense today, however accurately it corresponded to the facts merely and simply because we do not believe any longer that the fundamental harmonies of the universe are disclosed in numbers and geometrical figures But though this view of reality led Kepler astray in this case, it was close *enough to the truth to guide him aright to the* discovery of his three laws of planetary motion Therefore Kepler remains a great scientist to us, in spite of his erroneous reference to the Platonic bodies It is only when he talks of such things as the mind residing in the sun which listens to the planets, and puts down in musical notation the several tunes of the planets, that we no longer regard him as a scientist, but as a mystic We draw here a distinction between two kinds of error—namely, between ***scientific guesses*** which have turned out *to be* ***mistaken,*** and ***unscientific guesses*** which are not only false, but ***incompetent***

* * *

Scientists—*that* is creative scientists—spend their lives in trying to guess right They are sustained and guided therein by their heuristic passion We call their work creative because it changes the world as we see it, by deepening our understanding of it The change is irrevocable A problem that I have once solved can no longer puzzle me , I cannot guess what I already know Having made a discovery, I shall never see the world again as before My eyes have become different , I *have made myself into a person* seeing and thinking differently I have crossed a gap, the heuristic gap which lies between problem and discovery

To the extent to which discovery changes our interpretative framework, it is *logically* impossible to arrive at it by the continued application of our previous interpretative framework In other words, discovery is creative also in the sense that it is not to be achieved by the diligent application of any previously known and specifiable procedure Its *production* requires originality The application of existing rules can produce valuable surveys, but they can as little advance the principles of science as a poem can be written according to rule We have to cross the logical gap between a problem and its solution by relying on the unspecifiable impulse of our heuristic passion, and must undergo as we do so a change of our intellectual personality Like all ventures in which we comprehensively dispose of ourselves, such an intentional *change of our* personality requires a passionate motive to accomplish it Originality must be passionate

---

[2] Hume D A Treatise on Human Nature Book I part iv section vii

No register of health visitors is recommended but their qualification should continue to be protected by statutory regulations

Training should be financed from central funds provided mainly by appropriate contributions from local health authorities A uniform scale of training allowances should be payable by training centres to students willing to serve for a specified period in certain conditions

MAN-POWER AND RECRUITMENT

On the standards set by the working party, a target establishment of 11 500 full-time staff—an increase of some 3500 full-time workers—is needed To meet the need within ten years the number of students trained each year would have to rise from about 640 to 1100 The working party realise that the number of suitable trained nurses likely to be available each year is too small to guarantee expansion They therefore recommend concentration on direct entrants and the establishment of adequate integrated courses to attract them

The report advocates a vigorous recruitment policy in which an important place is given to the enhanced status of health visitors, the elimination of inessential work, and better conditions of work and pay

* Not including late returns

Conferences and Congresses

MEDICAL RESEARCH IN THE CARIBBEAN

THE first scientific meeting to be held under the auspices of the newly formed Advisory Committee for Medical Research in the West Indies met at the University College of the West Indies, Jamaica, on April 8 and 9, under the chairmanship of Sir HAROLD HIMSWORTH The large audience included representatives from seven West Indian territories 32 papers were presented, 3 being read by title Many papers were interim reports on current research The proceedings of the meeting and many of the papers are to be published in the *West Indian Medical Journal*, and there follow summaries of a few of the contributions

MAYARO VIRUS

Dr W G DOWNS, of Trinidad, reported that in 1954 his team at the Regional Virus Research Laboratory had isolated a new virus, later called the Mayaro virus, from the blood of 5 febrile patients They were also able to demonstrate the presence of antibodies to this virus in the blood of a number of Trinidad residents, using an antigen prepared from mouse serum In the same year the virus was isolated in Brazil and Bolivia, and possibly also in Uganda, but this latter virus may be a close relative rather than the Mayaro virus itself Nothing is known as yet of its epidemiology or of its importance as a human disease producing agent, but it is of interest that the virus was not isolated in Trinidad during 1955

CONTROL OF MALARIA

Dr GEORGE GIGLIOLI outlined the investigations which he had undertaken from 1923 onwards into the epidemiology of malaria and blackwater fever in British Guiana He was able to identify *Anopheles darlingi* and to establish that it was the sole malaria carrier of practical importance in British Guiana He studied the breeding, biting, and resting habits of this vector, and he noted that acidity of the water in certain areas prevented breeding But in the cultivated and settled coastal lands of British Guiana (low level, sea defences, immense irrigation canal network, flood fallow, and rice cultivation) control by the methods then available—before the first world war—was impossible

The advent of dicophane (D D T) brought a new significance to these researches, and the results achieved with its use were more complete than might have been hoped for Only occasional cases of malaria are now recorded in British Guiana and these are from the far interior, mainly along the Brazilian border The geological formations inland from the coastal belt, which drain very acid waters, form a barrier to the spread of *A darlingi* This, together with periodic application of dicophane to the houses along the alluvial banks of the rivers and smaller water courses, has eradicated this mosquito from the coastal plains and also prevents re invasion from the forest areas Malaria is thus a thing of the past in the coastal plain of British Guiana

Dr H P S GILLETTE described investigations showing the development of resistance to dicophane by *Aedes Ægypti* Field observations made during the yellow fever campaign of 1954 have been confirmed by detailed laboratory work

YAWS

Dr F J GOODEY, Dr C C GORDON, and Prof K R HILL (University College of the West Indies) indicated some limitations of the modern methods of treatment of yaws in the field, and described this disease as produced experimentally in the hamster Detailed long-term observations made in a small closed country community suggested three main points (1) serological reactions are of little assistance in the control of framboesia in the community, (2) approved medical methods of control are often both impractical and unsuccessful, (3) a large proportion of frambœsial lesions are not recognised as such The experimental work suggested that during a remission there is residual latent infection at the roots of the hair follicles This might explain the exacerbation of the disease at the site of an old scar in human cases Professor Hill and his colleagues also reported work on some immunological aspects of leprosy

VENO OCCLUSIVE DISEASE OF THE LIVER

Dr K L STUART outlined the clinical features of veno-occlusive disease of the liver[1] Infants between 1½ and 3 years of age are primarily affected by the acute disease, but older children and adults do not escape Most affected children are not malnourished In the acute stage, there is a sudden onset of abdominal distension due to a smooth, firm, slightly tender liver enlargement, which is often associated with an acute ascites Many patients recover rapidly, at least clinically, with or without treatment, but there may be (*a*) rapid death due to liver failure, (*b*) persistence of the disease been replaced some 50 years ago by the exact sciences, is now once more dug up by pseudo scientists from the lumber room of human fallacies, and like a trollop, newly attired in elegant dress and make up, is smuggled into respectable company, to which she does not belong "

---

[1] See *Lancet* 1955 ii 1284

Now, in a second paper,[7] he gave as a further example of this aberration an account of van t'Hoff's work which he "would have ignored like many other efforts of its kind" but for "the incomprehensible fact" of its warm recommendation by so distinguished a chemist as Wislicenus So Kolbe wrote

> "A certain Dr J H van t'Hoff, employed by the Veterinary Academy at Utrecht, appears to have no taste for exact chemical research He *found it more convenient* to mount Pegasus (borrowed no doubt from the Veterinary Academy) and to proclaim in his *La Chimie dans l'espace* how on his daring flight to the chemical Parnassus the atoms appeared to him disposed in world space "

Kolbe's comment on the introduction given by Wislicenus to van t'Hoff's theory reveals the principles of his criticism in further detail Wislicenus had written of "this real and important step in the advancement of the theory of carbon compounds, a step which was organic and internally necessary " Kolbe asks What is "the theory of carbon compounds? What is meant by saying that 'this step was organic and necessary' "? And he goes on "Wislicenus has here expelled himself from the ranks of exact scientists and has joined instead the nature philosophers of ominous memory who are separated only by a slender 'medium' from the spiritists "

Scientific opinion eventually repudiated Kolbe's attack on van t'Hoff and Wislicenus, but his suspicion of speculative chemistry ("paper chemistry") continued to be shared by most of the leading chemical journals, which refuse up to this day contributions containing no new experimental results In spite of the fact that chemistry is largely based on the speculations by Dalton,[8] Kekule, and van t'Hoff, which were initially unaccompanied by any experimental observations, chemists still remain suspicious of this kind of work Since they do not sufficiently trust themselves to distinguish true theoretical discoveries from empty speculations, they feel compelled to act on a presumption which may one day cause the rejection of a theoretical paper of supreme importance in favour of comparatively trivial experimental studies So difficult is it even for the expert in his own field to distinguish scientific merit from incompetent chatter by applying the criteria of empiricism

Nor does this apply only to purely theoretical discoveries The great controversy on the nature of alcoholic fermentation which, starting in 1839, went on for almost forty years, showed that the verification of an experimental observation may run into precisely the same difficulties From 1835 to 1837 no less than four independent observers (Cagnard de la Tour, Schwann, Kützing, and Turpin) had reported that yeast produced during fermentation was not a chemical precipitate, but consisted of living cellular organisms which multiplied by budding, and they had concluded that fermentation was a living function of yeast cells [9] But this went against the overmastering intellectual passion of contemporary scientists In 1828 Wohler had synthetised urea from inorganic materials and had triumphantly disproved thereby the existence of powers hitherto ascribed exclusively to living beings Liebig had followed suit by laying the foundations of a chemical approach to all living matter, and Berzelius had recognised that platinum could speed up reactions occurring in its presence, in the same way in which fermentation was caused by yeast All three great masters poured scorn on the claims which they regarded as a fantastic resurgence of the kind of "vitalism" they had banned for ever Wohler and Liebig published an elaborate skit making fun of these absurd speculations [10]

In 1857 Pasteur entered the lists on the side of the "vitalists" His investigations on yeast and putrefaction involved him at the same time in another fierce controversy of longer standing—the question of "spontaneous generation" In this, too, he was on the side considered at the time reactionary (and is still so considered in the Soviet Union), which denied that living beings could be produced experimentally from dead matter [11]

The reason why both these controversies dragged on indefinitely is revealed by a remark of Pasteur concerning his own arguments for regarding fermentation as a function of the living cells of yeast "If anyone should say that my conclusions go beyond the established facts [he wrote] I would agree, in the sense that I have taken my stand unreservedly in an order of ideas which strictly speaking, cannot be irrefutably demonstrated "[12] This order of ideas was therefore separated by a logical gap from that entertained by Liebig, Wohler, and many other great men of his time The schism was eventually bridged by a conceptual reform, induced by Buchner's discovery in 1897 of zymase in the liquor squeezed out of yeast cells The agent of fermentation was proved a dead catalyst of the kind imagined by Liebig and Berzelius but it also proved a vital organ of yeast cells, as Pasteur and his precursors since Cagnard de la Tour had affirmed the new conception of intracellular enzymes combined these two aspects [13]

* * *

The great scientific controversies which I have just recalled were conducted in passionate accents, as was inevitable between contestants who shared no common framework within which a more impersonal procedure could be followed Kolbe could not argue against van t'Hoff He quoted with ironical glee van t'Hoff's description of the disposition of atoms in spirals, which to him was sufficient evidence that the new theory was a tissue of fancies From his own point of view he was right in refusing to enter into any detailed argument on these lines, since he denied that one could argue rationally in terms of such wild ideas The ironical travesty by which Wohler and Liebig replied to the papers of Cagnard de la Tour, Schwann, and others, claiming that fermentation is a function of living yeast cells, sprang from the same view that an argument believed to be wholly specious cannot be seriously discussed point by point A Western scientist challenged to answer Lysenko's biological theories would similarly refuse to discuss them on the Marxist-Leninist grounds on which they were put forward, while Lysenko would refuse to consider the statistical evidence

---

[7] Kolbe A W H *Ibid* 1877 15 473 The above summary of the first paper is quoted from the second paper

[8] For the case of John Dalton see H E Roscoe and A Harden A New View of the Origin of Dalton's Atomic Theory London 1896 p 50

[9] Dubos R J Louis Pasteur London 1950 pp 120–121

[10] Wohler and Liebig *Ann Pharm* 1839 29, 100

[11] See for example, the violent attacks on Pasteur by Pisarev published in 1865 (Coquart A Dmitri Pisarev Paris 1946 p 336 ff) Experiments acknowledged today in the Soviet Union as proofs of the spontaneous generation of cellular organisms were carried out by Lepeshinskaia (see Th Dobzhansky Proceedings of the Hamburg Congress on Science and Freedom *London, 1955, p 219)*

[12] Dubos, R J Op cit p 128 J B Conant in Pasteur's and *Tyndall's Study of Spontaneous Generation* (Harvard University Press 1953), suggests (p 15) that the most convincing evidence for the impossibility of spontaneous generation is to be found in the whole fabric of the results of the study of *pure* (bacterial) cultures in the last sixty or seventy years The author implies here that all the experiments made to decide this question from the inception of Spalanzani's studies in 1768 up to 1880–90 could be interpreted in terms of either opposing systems of thought

[13] The way an apposite new conception can reconcile two alternative systems of interpretation which hitherto completely excluded each other is illustrated by Braid's conception of 'hypnosis' which acknowledged the reality of the very features of Mesmerism which were hitherto taken to prove its fraudulence while rejecting the evidence for 'animal magnetism' which had been regarded as its claim to scientific solidity but was in fact illusory

Correction of Uterine Retroversion

M. MOORE WHITE (London) said that the correction of uterine retroversion as an aid to fertility has fallen into disrepute, but if performed for certain indications it is worth while. The faulty position of the uterus can hinder access of sperm to the cervix, cause kinking of the tubes at the uterine angles (a condition manifested when carbon dioxide fails to enter the tubes, on insufflation, until the uterus has been elevated), result in œdema both of the uterus and prolapsed ovaries, and be a cause of pelvic pain, backache, and dyspareunia. Operative correction is indicated if manual reposition is unsuccessful, the method varying according to the condition found at operation.

Iatrogenic Sterility

W. T. POMMERENKE (Rochester, N.Y.) reported an analysis of 9200 consecutive operations in the gynæcological service of a general hospital over a seven year period, 1948–54. This showed that 2035 (22.1%) of those operations were of such a nature that infertility would have been an inevitable consequence if the women had been otherwise functionally and anatomically intact. True, a significant number of patients had already been doomed to infertility because of age or pelvic disorder. However, the high incidence of sterilising procedures in young women in whom the desire for child bearing is paramount hardly bespeaks the ultimate in diagnosis or treatment. The rightful place of surgery in gynæcology is admitted, but quite apart from other unpredictable sequelæ, sterility may follow as a result of ill advised or heedlessly radical surgery. The number of absolute indications for sterilising operations is decreasing.

Urinary Hormone Determinations in Chronic Aborters

M. ROLAND and E. VEPROVSKY (New York City) stated that the value of urinary hormone determinations in chronic aborters, particularly of pregnanediol, appears to be limited at present—chiefly because we do not know the exact mechanism of progesterone metabolism. The methods now used account for only 20–30% of the converted progesterone. Even this estimated amount appears to be a "pregnanediol complex" which includes pregnanolone as well as different types of pregnanediol. Our interpretation will remain inaccurate and of limited value until we know more of progesterone metabolism. When a sudden drop in the urinary pregnanediol excretion occurs in chronic aborters, particularly during the first trimester of pregnancy, it is usually too late to attempt any type of therapy. When substitutional therapy has been started at the initiation of pregnancy, studies of the urinary hormone excretion may be of considerable value. In habitual aborters where the endometrial biopsy premenstrually demonstrates poor secretory activity, it is advisable to determine whether this is due to a lack of progesterone or to an endometrium which responds poorly to this hormone. The pregnanediol determination, evaluated together with the endometrial biopsy, may aid in ruling out one of these possibilities. Where a lack of progesterone is evident, replacement therapy might be indicated. High doses of oral progesterone were used as therapy in this series.

Therapeutic Experiments in Female Infertility

A. SHARMAN (Glasgow) stated that until ten years ago he performed tubal insufflations routinely both as a diagnostic and as a therapeutic procedure in all cases of primary sterility at the sterility clinic and in the wards of the Royal Samaritan Hospital for Women, Glasgow. Since then the procedure has been discontinued at the sterility clinic, as a routine measure, so that comparative experiments might be carried out, not only to assess the results of other methods of treatment but also to attempt a critical evaluation of the therapeutic merits of insufflation. A total of 2089 primary sterility patients were followed for twelve months, 893 after insufflation, 253 after the passing of a uterine sound, 286 after bimanual examination, 198 after commencing injections of progesterone combined with œstradiol benzoate, 300 after the oral administration of a mixture of ethisterone and ethinyl œstradiol, and 159 after the oral administration of inert tablets. The pregnancy rates at the end of the year were respectively, 17.4%, 17.8%, 10.8%, 16.6%, 14.3%, and 12.0%. In a series of nontreated and unexamined patients (355), who were merely interrogated and asked to return after their next period, 3 had no period following their visit to the clinic and were subsequently found to be pregnant (0.8%). Of 301 hospital inpatients, who were treated while the above hormone studies were proceeding, 67 (22.3%) became pregnant within twelve months of their stay in hospital.

Functional Aspects of Uterine Irritability and Tubal Occlusion

J. A. STALLWORTHY (Oxford) suggested guides to the clinician responsible for advising on infertility problems. (1) Every case should be investigated in full before advising on any one aspect of it. This demands knowledge of the male factor, ovulation, the uterus and endometrium, and tubal function. Unsuspected lesions, such as tuberculosis, will be discovered in this way. (2) Functional occlusion is more common than organic blockage. (3) Unilateral cornual occlusion in the absence of previous surgical intervention is most likely due to uterine irritability. (4) The radiological picture of bilateral functional cornual occlusion is identical with that of organic blockage following postabortal or puerperal sepsis. (5) Repeated negative tests by both insufflation and salpingography are not conclusive evidence of organic blockage. Reassurance, sedatives, and spasmolytics will reduce but not eliminate, errors. (6) The final diagnosis between functional and organic blockage is made only at operation and even then may be difficult. Retrograde insufflation should precede tubal implantation. The pathological report on tissue excised is the ultimate proof—or reproof!

Bilateral Ovarian Wedge Resection

I. F. STEIN (Chicago, Ill.) followed, for as long as twenty five years patients on whom bilateral ovarian wedge resection was performed for bilateral polycystic ovaries. He is convinced that this operative procedure, performed in carefully selected cases which conform to the definite syndrome restores reproductive function. He stated that in the entire series there has been no recurrence of bilateral polycystic ovaries, nor has there been a single instance of carcinoma of the endometrium. In some instances, as at cæsarean section and at hysterectomy, he has had the opportunity of inspecting the ovaries previously resected, and found them normal in appearance. In a few patients, postoperative fibrous adhesions were observed at laparotomy or by culdoscopy. However, pregnancy occurred despite the ovarian adhesions. He emphasised that the bilateral ovarian wedge resection is the treatment of choice and the beneficial effects are not self limited but last throughout the reproductive life of the woman.

Conception Following Tubal-patency Tests or Endometrial Biopsies

G. I. M. SWYER and H. H. FOURACRE BARNS (London) spoke of the prevalent belief that tubal patency tests have a therapeutic as well as a merely diagnostic value. It is further commonly held, they said, that conception is more likely to follow hysterosalpingography, especially if this be carried out with an oily rather than a non oily medium, than to follow uterotubal insufflation. However, no acceptable evidence in support of these views seems to be available, and they sought to provide this by comparing the incidence of conception in the arbitrarily chosen period of six months following a tubal patency test (in women with no obvious infertility factors, and with apparently fertile husbands) with that in a similar period following the performance of an endometrial biopsy—for which no special therapeutic value has ever been claimed. The differences in these incidences of conception are of doubtful significance and do not provide clear evidence in support of the above mentioned beliefs.

Donor Insemination

P. T. TOPKINS (New York) reported that approximately 80% of regularly menstruating, gynæcologically normal women who undergo donor insemination become pregnant. Conception occurs within six months in almost 90% of successful cases, within three months in almost 75%, and during the first month in about 33% of the cases. If conception does not occur within the first six months it becomes increasingly difficult to attain. The most productive method of determining insemination time is the Ogino Knaus calculation. Of those who conceive, approximately 15% ultimately abort.

Functional Significance of the Cervical Mucus

B. ZONDEK (Israel) gave a short review of the physical and chemical properties of the cervical mucus; the phenomena of arborisation with crystallisation of the dried mucus was discussed in detail.

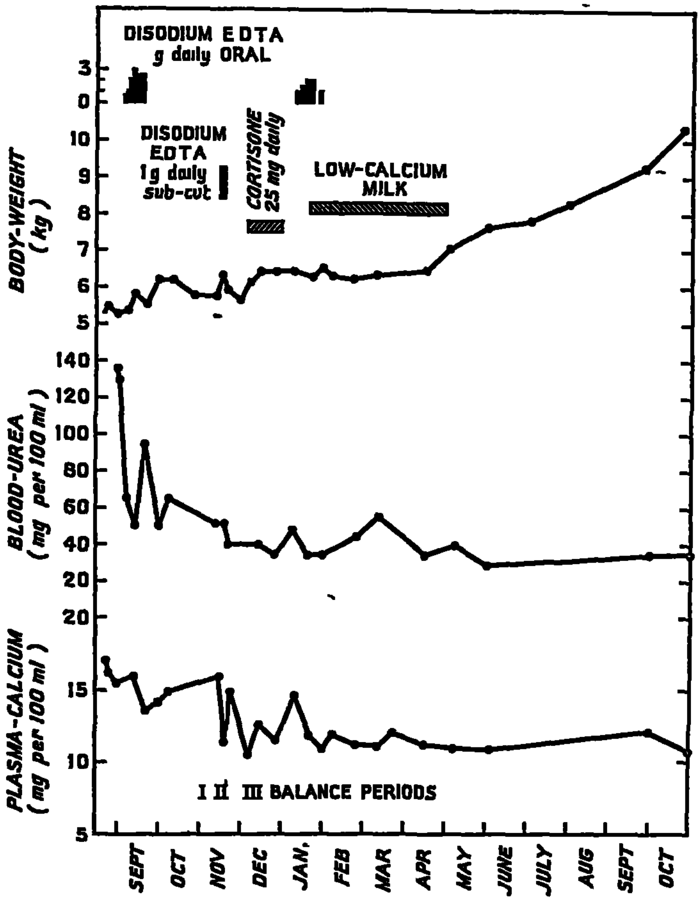

Fig 1—Case 1 variations in plasma calcium and blood urea levels and weight in response to EDTA, cortisone, and low-calcium milk (details in table I)

was started, 2 pints being given daily for ten days The amount of EDTA required to decalcify 2 pints is about 4 g, but we began with 0 5 g and increased this over a week to a daily dose of 3 g After two days at this level several loose stools were passed, and the dose was reduced to 2 5 g daily Soybean milk, still with EDTA 2 5 g daily, was then substituted for the breast milk but was not taken well Vomiting, frequent stools, and dehydration developed during the following week Both EDTA and soy feeds were then stopped The plasma calcium level had fallen to 13 6 mg per 100 ml Fresh cow's milk thickened with corn flour proved the best diet for restoring lost weight and general well being, but the plasma calcium level had risen to 14 8 mg per 100 ml after fourteen days on this diet (Oct 6, 1954)

Balance studies were started on Nov 3, 1954, the details are shown in table II and fig 2 After the control period disodium EDTA 1 g was given subcutaneously once daily for five days until signs of gastro intestinal disturbance developed By the third day of treatment the plasma calcium level had fallen from 15 7 to 11 4 mg per 100 ml, but it rose again to 14 7 mg per 100 ml a day after the EDTA had been discontinued After nine days without treatment a course of oral cortisone 25 mg daily was started on Nov 30, 1954, and this was followed by a gain in weight (balance period III) There was a striking improvement in appetite and general well being, and it became possible to add gravy and potatoes to the diet The plasma calcium level fell to satisfactory levels but rose after the cortisone therapy was stopped on Jan 1, 1955 Breast milk and oral EDTA (up to 2 g daily) were then given until low calcium milk ('Locasol,' Trufood) was obtainable on Jan 21, and thereafter the plasma calcium level remained below 12 mg per 100 ml By Feb 11 the child was feeding well enough to be sent home on locasol and a low calcium mixed diet In May she began taking cow's milk and bread with the standard fortification with calcium In July her Hb had decreased to 6 56 g per 100 ml, and iron was given In September, 1955, at the age of 20 months, she had just begun to walk and to wave her hand The systolic murmur was less intense than formerly, but the ocular pareses were unaltered She was very bright and happy

Case 2—A boy, born on Jan 11, 1954, by forceps delivery because of disproportion, weighed only 5 lb 5 oz although he was said to be overdue He was the first child of healthy young parents, there was no relevant family history He was breast fed for a week and then changed to half cream National dried milk because appendicitis developed in his mother His progress was satisfactory, and at the age of 3 months, when mixed feeding was started, he weighed 12 lb 8 oz About the age of 4 months he began to vomit occasionally after feeds but continued to gain weight Until he was 6 months old he passed one soft stool daily, but thereafter his stools became hard and less frequent At 7 months the vomiting began to increase in frequency and severity, and his family doctor prescribed 'Milk of Magnesia' In spite of this the constipation and vomiting continued, and the boy began to refuse feeds and to lose weight He was therefore admitted to Dundee Royal Infirmary on Sept 2, 1954, at the age of 8 months, under the care of Prof J L Henderson At this time he was on a diet of full cream National dried milk, strained soups sieved vegetables and fruits, and cereal foods He had also had half a teaspoonful of National cod liver oil compound (400 I U of vitamin D) daily since the age of 2 weeks

On admission he was pale and rather irritable and weighed 12 lb 15 oz He had general muscular hypotonia with lax skin but no clinical dehydration His anterior fontanelle admitted a finger tip No murmur or other cardiovascular abnormality was present, and electrocardiography showed no prolongation of the P–R interval There was slight inflammation of the right tympanic membrane

Investigations—The urine contained no protein or sugar and only a few pus cells Its pH was 7 5, and it was sterile on culture Radiography of the heart, lungs, skull, and long bones showed no abnormality The plasma calcium level was 14 8 mg per 100 ml and the blood urea level 50 mg per 100 ml Values for other electrolytes are given in table III

Treatment and progress—During the first six weeks in hospital the infant was given fresh cow's milk with no added vitamin D His general condition improved and vomiting became less frequent, but in spite of this his weight gradually fell and the plasma-calcium level rose to 18 8 mg per 100 ml Further culture of the urine grew *Escherichia coli*, and streptomycin was given for six days

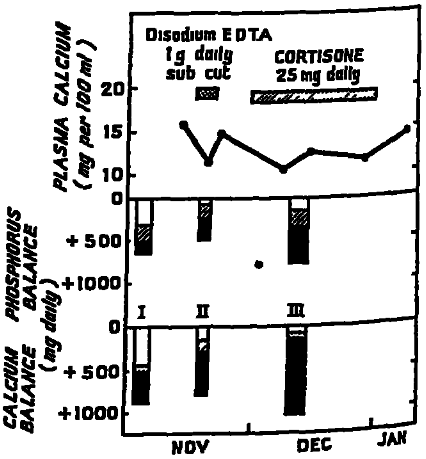

Fig 2—Case 1 balance data for calcium and phosphorus Intake is plotted downwards from baseline faecal output (black) and urinary output (hatched) are then plotted upwards A positive balance (excess of intake over output) is shown by a clear space below the base line (details in table II)

Balance studies were started on Oct 19, 1954, the details are shown in table IV and fig 3 The administration of cortisone from Oct 27, 1954, produced a dramatic improvement in the child's general well being, his weight increased, his appetite improved, and he lost his fretfulness and irritability This improvement coincided with a fall in the plasma calcium level, and on the one occasion during ten weeks on cortisone when the plasma calcium level rose to a high value after the dosage had been reduced, the irritability and anorexia returned, to disappear again as the plasma calcium level fell when the dosage of cortisone 25 mg was resumed

Letters to the Editor

ANÆSTHESIA IN OBSTETRICS

SIR,—I would like to comment on a few of the points raised by Dr Coleman and Dr Day in their interesting article (May 19) and by your annotation in the same issue.

I am not convinced that Coleman and Day have solved, by the method they advocate, the problem which they have posed. The results of their experience with a method involving endotracheal intubation are impressive, but no better than those which should be—and I feel are—obtained by equally competent anæsthetists working with drugs and equipment to which they are accustomed.

Those who claim that vomiting is a perpetual hazard in obstetric cases, however skilfully the anæsthetic be administered, indicate that it is most likely to occur during the induction period—the phrase “stormy induction” occurs with great regularity in the tales of disaster of this class. Yet Coleman and Day make no special provision for this period other than the prophylactic one of having suction apparatus handy. I calculate that, unless the anæsthetist in charge has a medically competent associate working with him in the labour ward or the theatre (a rare event except in teaching units), the time elapsing between application of the anæsthetic mask and inflation of the endotracheal cuff is likely to be more than four minutes. Attempts to hurry induction, or premature attempts to intubate, would merely invite regurgitation or vomiting. You go some way towards making this point in your annotation, but I feel that even so you are too confident about the modification you suggest.

I believe that Coleman and Day introduce an unnecessary hazard into the anæsthetic management of these cases. If the postulate that “the woman in labour presents problems similar to those in cases of intestinal obstruction” is accepted, then naturally the management of each must follow a similar pattern. It is now accepted teaching that a large-bore gastric tube (definitely not a Ryle's tube) should be passed preoperatively on each patient with intestinal obstruction. To comment as do Coleman and Day that the passage of such a tube increases the “fear and distress” of the woman in labour is merely to invite the reply “better that than a disastrous induction.” The observation of Coleman and Day that “commonly the quantity of fluid and debris recovered is small” must mean that if the gastric tube was of wide enough bore, the stomach was virtually empty.

There are, however, two other aspects of this question which I consider to be of very considerable importance. Coleman and Day reiterate the long held contention that during labour the gastric emptying-time is prolonged. I have recently attempted to show,[1] with the help of Dr F. Hutton, radiologist at the Central Middlesex Hospital, for whose cooperation I am grateful, that this is by no means true. We performed barium-meal examinations on twelve women in established labour, and the times of gastric emptying showed the same range of variation as in the normal subject (from 2 hours to over 8 hours in our series). This generalisation we can apply only to patients who are on fluid or semi solid diets of the type which should by now be the rule for all patients in labour.

The conclusion to be drawn from this investigation was that the renowned hazard of obstetric anæsthesia is not due to “the inevitable retention of gastric contents in labour.” I feel that the important factors are the choice of agents used for induction of anæsthesia and the competence with which the anæsthetist is able to use these agents. Most anæsthetists in this country use thiopentone for induction in the majority of their cases. Yet in their obstetric practice they revert to a sequence of inhalation anæsthetics which in the non-sedated patient invites the hazards that may be grouped under the term “stormy induction.” Thiopentone provides a smooth and rapid induction, and, at least in a dose of about 250 mg., exerts no undue depressant effect upon the child regardless of how long the obstetrician takes over the delivery.[2]

The employment of thiopentone is often opposed on the ground that it demands a high standard of professional competency. I feel that no practitioner lacking that degree of competence should be permitted to indulge in obstetric anæsthesia. Although I claim that the method I suggest is the most satisfactory, it would be stupid to deny that any method, willingly undertaken by a competent anæsthetist in a large series of cases, will be associated with a very low disaster-rate.

This of course, as you suggest at the conclusion of your annotation is the real crux of the matter. I read with great interest Professor Russell's article (May 12) and your editorial comment. I feel very strongly that, just as “dabbling in midwifery must be discouraged, in much the same way as dabbling in surgery is discouraged,” so should the employment of an “occasional” anæsthetist be countered as far as possible, and also the application of the “occasional” technique for potentially poor-risk cases (i.e., non-routine inductions for obstetric patients). I have long believed that there should be a general-practitioner anæsthetists' list analogous to the G.P. obstetricians' list. I fail to understand why anæsthetics has been allowed to assume the place it now holds in the curriculum of undergraduates. Students on the general surgical and obstetric “firms” are rarely permitted to do more than assist in the theatre, or to perform a vaginal examination before the obstetrician applies forceps. Yet they are expected to conduct up to twenty major and minor anæsthetic cases (albeit under supervision) and are then encouraged to consider themselves competent to conduct such cases (in hospital or domiciliary practice) as soon as they qualify. Surely it would be enough that undergraduates be given a short course of lectures on anæsthetics and be taught how to maintain the airway of an unconscious patient? This would help to reduce an already overburdened curriculum, and might also possibly enable the senior anæsthetists to supervise more closely the work of their graduate trainees in the labour wards—at least in the daytime. It would also help to discourage general practitioners not on the anæsthetists' list from giving occasional anæsthetics.

To summarise: I suggest that if (*a*) domiciliary anæsthetics (which are mainly for obstetric cases) were given only by doctors who have had postgraduate experience in the specialty, and (*b*) the routine of induction of anæsthesia for obstetric cases in both domiciliary and hospital practice were similar to those used by the individual anæsthetist for the majority of his general surgical cases, we would be much closer to solving this pressing problem than we are likely to get by pursuing some panacea in the form of a fool-proof anæsthetic.

London, W.1. J. SELWYN CRAWFORD

. We refer to Dr Crawford's work on thiopentone levels in an annotation on p. 898.—ED. L.

SIR,—You leave unanswered several important questions in your annotation regarding the future of obstetric anæsthesia.

The problem, as you state, has become increasingly important in the post-war years as one of the major causes of maternal mortality and morbidity in hospital obstetrics. Its dangers can, however, be greatly reduced and strictly circumscribed.

It is possible to conduct the large majority of hospital and almost all domiciliary forceps deliveries under

I–III, with added custard in period IV and added apple in period V Samples of the diets for each period were analysed

The bulked stools were strongly acidified with hydrochloric acid before being mixed mechanically Fæcal and dietary samples were ashed in silica crucibles, dissolved in three washings of hot 2*N* hydrochloric acid, and made up to volume

Urine was mixed, strongly acidified, and allowed to stand at least a week (to precipitate uric acid), and the supernatant fluid was sampled (Badenoch and Fourman 1954)

For the calcium determinations McCrudden's method, modified slightly from Hawk et al (1947), was used on the extracts and on the urine, and also, in case 1, on samples of ashed urine For the phosphate determinations the method of Fiske and Subbarow (1925) was used

All the results represent at least two estimations on each of two samples

Balance Studies

The results of balance studies are given in tables II and IV and figs 2 and 3 Certain features are common to both cases In the control periods there was a large absorption of calcium (57 5% and 61%) and of phosphorus (74% and 84%) producing a strongly positive balance despite relatively large outputs in the urine At this time each infant had severe hypercalcæmia and moderate azotæmia, and therefore only one control balance study was made

Oral cortisone 25 mg daily in each case more than doubled the fæcal calcium and phosphorus and diminished the retention of calcium by about 330 mg a day and of phosphorus by about 130 mg a day The urinary calcium increased from 45 to 87 mg a day in case 2 but diminished from 55 to 21 mg a day in case 1, although the latter balance study was not started until the tenth day of treatment with cortisone The amount of urinary phosphorus was not significantly altered The plasma calcium and plasma-phosphorus levels returned rapidly to near normal, and the clinical status improved greatly A week after the start of cortisone therapy the plasma-calcium level had dropped from 19 0 to 12 6 mg per 100 ml in case 2 and from 14 7 to 10 6 mg per 100 ml in case 1

Subsequently in case 1 the cortisone was discontinued after a month, and later the plasma-calcium level rose from 11 5 to 14 5 mg per 100 ml , it fell again while oral EDTA and breast milk, and later locasol (fig 1), were being given

In case 2 clinical improvement on cortisone permitted a much greater intake of milk during period III, and the retention of calcium and phosphorus then exceeded that of the control period, although the proportion of each

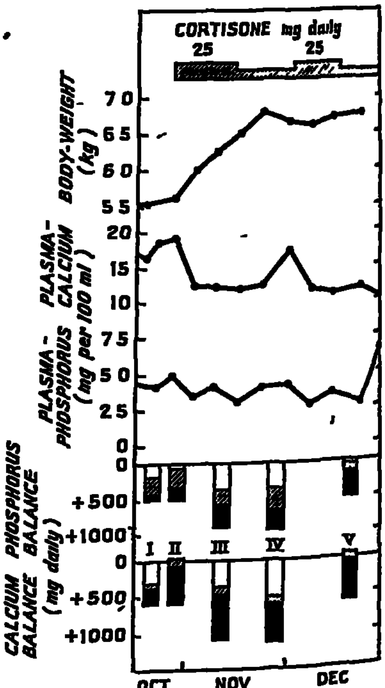

Fig 3—Case 2 balance data (details in table IV)

TABLE IV—BALANCE FINDINGS IN CASE 2

Period	Therapy	Calcium (mg daily)						Phosphorus (mg daily)					
		Excretion			Diet	Balance	Absorption (%)	Excretion			Diet	Balance	Absorption (%)
		Fæces	Urine	Total				Fæces	Urine	Total

arachidonic from 0 8 to 0 3 g In 1952 the E F A content was about 3 2 g per 2500 calories An idea of the human requirements of E F A was indicated by mentioning the 13 3 g E F A per 2500 calories of human milk This figure is strikingly close to the figures mentioned above

Copenhagen　JOHAN E NYROP

LYMPHATIC DRAINAGE OF THE BREAST

SIR,—The pathways of lymphatic drainage of the breast have been studied by intravital methods Solutions containing iron and patent blue, and in some cases a radioactive tracer, have been injected into the tissues of the breast A proportion of this is taken up by the lymphatics thus demonstrating the lymphatics during operation and in cleared surgical and post-mortem specimens[1]

In addition to the commonly described axillary and internal mammary pathways, lymphatic vessels can be seen to accompany the lateral perforating branches of the intercostal blood vessels that supply the breast, these drain into the posterior intercostal lymph nodes lying between the necks of the ribs in close relation to the vertebræ

Post-mortem examination of the posterior intercostal nodes has shown that they may be invaded by carcinoma of the breast, and there is also evidence that this pathway may be involved fairly early in the spread of the tumour in some cases If routine postoperative radiotherapy is employed in the treatment of this disease, it would seem rational to include these nodes in the treated area

Middlesex Hospital
London W 1　R T TURNER-WARWICK

DIABETES AND PARITY

SIR,—The data which Dr Pyke has reported in his article of June 2 are of great interest, and his interpretation of them—that the chance of a woman developing diabetes after the age of 45 increases with the number of children she has had—is probably correct The alternative explanation—that women who are genetically predisposed to diabetes are more fertile than normal women —must be carefully considered, however, and perhaps Dr Pyke could report further details of his patients which might help to answer the problem

Diabetes mellitus has such a high frequency in the population that recurrent mutation alone cannot account for its gene frequency having reached the estimated 15% It is likely therefore that the diabetic genes confer some biological advantage to counter their loss from the population due to young diabetics failing to reproduce in the generations before insulin therapy was introduced The disease is usually inherited as a recessive character, and the simplest mechanism by which the polymorphism could be maintained in the population would be by individuals heterozygous for a diabetic gene being generally more fertile than individuals without the gene, data published previously suggest that this may indeed be so, as the parents of diabetics have in several series been found to have more children than do the general population If the heterozygotes are more fertile than normal people, it would be reasonable to expect diabetics also to be more fertile than normal before they develop the disease, and it would be of great interest to know if Dr Pyke's data support this expectation or not

One would expect to find a higher percentage of diabetic women in the higher parity groups, and a lower percentage in the lower parity groups, than is found with normal women Dr Pyke's tables II and IV show that this is what he finds His percentage of nulliparæ (19 6%) is so very much lower than the normal (32 6%) that it would be of interest to know what proportion of them remained unmarried up to the menopause, compared with the proportion found in the nulliparæ of the general population If the proportions in the two groups are similar it could be regarded as evidence in favour of the explanation of the data being that parity increases the chances of developing diabetes, but if the proportion of unmarried is higher in the diabetic nulliparæ it would favour the hypothesis that the diabetic genes increase fertility

Heredity Clinic
David Lewis Northern Hospital
Liverpool 3　R B MCCONNELL

SIR,—Is the apparent "effect of parity" on women due to parity as such, or to the "stress" involved in bringing up more children under present conditions? Is there, I wonder, any difference in the incidence of diabetes in mothers with and without domestic help?

Sanderstead Surrey　EVE STRATON

HOME CONFINEMENTS

SIR,—The four London regional obstetric committees have been concerned for a long time that practitioners who are admitted to the list of general-practitioner obstetricians should have had adequate experience Since 1948 they have admitted to the list practitioners who have been responsible for 30 confinements within a period of three years or who have held a resident obstetric post

They have now decided that, save in exceptional circumstances, practitioners who have qualified since Jan 1, 1951, and who wish to be included in the London list of general-practitioner obstetricians must, as from May 1, 1957, have held a resident house job in obstetrics for a period of six months

Any applications received before May 1, 1957, will be considered in the light of the standards mentioned in the second sentence of this letter

J A SCOTT

PARAPLEGIA FOLLOWING SPINAL ANÆSTHESIA

SIR,—Sir Francis Walshe's usual, delightful, pellucid English for once leads him into obscurity Paragraphs 8 and 9 of his letter (June 2) detract from what is otherwise a logical theoretical argument which arrives at an incontrovertible conclusion "There is some special risk in spinal anæsthesia"

Had the corpus of anæsthetists been present, as I was, at a symposium in Bangalore in 1946 on Complications of Spinal Anæsthesia, and seen the wardful of paraplegia and spinal osteomyelitis there assembled, they would have arrived at the same conclusion as Sir Francis on the evidence before their eyes

They would have resolved, as I did, never to introduce foreign bodies into the theca again

Anæsthetists Sir Robert Macintosh amongst them, need not ' substitute their naïve optimism for knowledge " No further research is needed Abandon spinal anæsthesia

London S W 3　L H LERMAN

SIR,—This subject is, as the correspondence shows, one fraught with difficulties Without wishing to add to these, I would like to mention that I have injected into a patient with inoperable carcinoma the phenol glycerin mixture of Maher[1] into the theca below L5, without any neurological changes whatsoever ensuing A week later the injection was repeated, this time using phenol-glycerin-water Whilst the perineal pain for which it had been given was slightly improved, no other neurological changes immediate or remote were demonstrable

In addition, I feel that we must go in for some hard thinking regarding the justification of the use of spinal stated that addition of the vitamin to the milk mixture in manufacture may be uneven (Spur 1953), hence there may be an unknown difference between the estimated and the actual dosage. The inaccuracy of the methods of assaying vitamin D and the need to ensure a product of at least the required potency are likely to lead to excessive supplementation with the vitamin. The importance of the relative potency of the different forms of vitamin D cannot at present be assessed (Bicknell and Prescott 1953).

---

[1] Turner Warwick R T *Lancet* 1955 ii 1371

[1] *Lancet* 1955 i 118

The apparent absence of idiopathic hypercalcæmia in the United States (H. E. Harrison, personal communication) and Canada (D. A. McGreal, personal communication) and its rarity in Sweden (Mellander 1955) may be related to the smaller intake of vitamin D in milk in these countries. The contrast is striking, for in the United States fortified whole milk and reconstituted evaporated milk contain about 400 I.U. per U.S. quart (946 ml.) (American Medical Association 1955), whereas in the United Kingdom reconstituted National dried milk has contained at least 1400 I.U. per quart (1152 ml.) for the past ten years. In Finland, where milk is not fortified, hypercalcæmia has been reported in 59 cases of interstitial plasma cell pneumonia (Hallman 1955), but 58 of these infants had had previous massive dosage of vitamin D (500,000–3,000,000 I.U.) as a prophylaxis against rickets.

If hypervitaminosis D, due either to overdosage or to increased sensitivity, is the main cause of hypercalcæmia, other signs of overaction of the vitamin might well be found. The nephrocalcinosis and renal insufficiency in case 2 and in other fatal cases might be explained by vitamin-D overactivity. Renal disease can increase the toxicity of vitamin D in rats (Opper 1941) and man (Anning et al. 1948, Chaplin et al. 1951), and this interrelationship may lead to a vicious circle when hypercalcæmia has begun to impair renal function, as it always does eventually. The recurring urinary infections in idiopathic hypercalcæmia also presumably increase the susceptibility to the vitamin's action.

Neither of our patients showed the lines of abnormally dense bone near the epiphyses of the long bones as described in hypervitaminosis D by Ross and Williams (1939). Possibly, however, the osteosclerosis in some severe cases of chronic hypercalcæmia (Schlesinger et al. 1956) may partly be due to this vitamin. Low plasma alkaline phosphatase levels, hypercholesterolæmia, and hyperglobulinæmia have been recorded in some cases of this syndrome, and also in hypervitaminosis D (Ross and Williams 1939, Anning et al. 1948, Powell et al. 1948, Payne 1952, Bonham Carter et al. 1955).

Action of Cortisone

Under the influence of cortisone the plasma calcium levels of our patients rapidly fell to normal or near normal values. Cortisone could achieve this result by increasing the urinary excretion of calcium, increasing the secretion of calcium into the gut, decreasing the absorption of calcium from the gut, or redistributing calcium within the body.

Increased elimination of calcium in the urine could have played no significant rôle in our patients, because in case 2 the increase was only about 40 mg. a day, whereas in case 1 there was a decrease of more than 30 mg. a day in spite of a larger intake.

On the other hand, the effect of cortisone in increasing the fæcal calcium was in each case large, indeed so large that this change alone could account quantitatively for the rapid fall in the plasma calcium level.

We could not, however, determine whether increased secretion or decreased absorption of calcium was mainly responsible for the increased fæcal calcium. If cortisone acts as a direct antagonist to vitamin D, as suggested by Anderson et al. (1954) in reference to hypercalcæmic sarcoidosis, it must do so by decreasing the absorption of calcium. Nevertheless cortisone may also increase the secretion of calcium into the gut. Thus a patient with Cushing's syndrome, receiving corticotrophin 50 mg. a day, excreted in the fæces an amount of calcium which exceeded the dietary intake (773 mg.) by 1400 mg. a day (Soffer et al. 1950). We have obtained a similar result in a four-day balance study of a man with asthma receiving 200 mg. cortisone daily. The fæcal calcium (554 mg. a day) exceeded the dietary calcium (291 mg. a day) by 263 mg. a day (unpublished work).

The results of our balance studies do not require us to invoke any other mechanism for the decrease in the plasma calcium level by cortisone than the action of increasing the fæcal calcium, but there may well have been some redistribution of calcium within the body. This is suggested by the relatively low plasma calcium levels in case 2 during period III, when there was a large retention of calcium.

Treatment

The clinical improvement in our patients accompanied pari passu the fall in the plasma calcium level whether this was due to cortisone, E.D.T.A., or simply a small intake of calcium. The first essential in treatment is therefore the reduction of the hypercalcæmia. This is effected by a diet without added vitamin D and containing as little calcium as possible, certainly not more than 300 mg. a day (cow's milk contains about 1400 mg. of calcium per quart). The basis of such a diet may be a low calcium milk powder (e.g., locasol) or cow's milk treated with a cation exchange resin which substitutes sodium, potassium, and magnesium for calcium, supplemented when possible in either case by a cereal containing little calcium—e.g., 'Farola' and 'Glaxo Low Calcium Cereal Food' (available at present only through hospitals). The cation exchange process is complicated and time consuming and is becoming less necessary with the increasing availability of commercial low calcium milk powders. Using such diets Ferguson and McGowan (1954) found that the serum calcium level became normal in two to six weeks. Supplementary iron should be given with these modified milks.

During the initial phase of treatment no vitamin D supplements should be given. After normal blood calcium levels have been attained, the intake of calcium can be gradually increased, preferably as fresh cow's milk, and later a small amount of vitamin D should be added to prevent rickets. Alkalis should be avoided because they are likely to favour the deposition of calcium in the kidneys, and a generous intake of fluid will minimise the possibility of metastatic calcification in the renal tract.

Cortisone should be used whenever it is desirable to achieve a more rapid return of the plasma calcium level to normal, but it is unnecessary to use it in the more common mild cases. The balance data in case 2 show that cortisone was effective in reversing the positive calcium balance only when the dietary calcium was restricted to about 600 mg. a day. Cortisone 25 mg. daily for an infant aged up to 1 year produces a satisfactory clinical and biochemical response. Whenever cortisone is given for more than a few days, it is wise to supplement the diet with potassium chloride, unless the child has significant uræmia.

We do not recommend treatment with E.D.T.A., although we found it effective in reducing hypercalcæmia, because of the gastro-intestinal irritation. Moreover a tendency to hæmorrhages and renal tubular damage may follow the intravenous administration of large doses of E.D.T.A. (Wishinsky et al. 1953, Dudley et al. 1955).

The absorption of calcium might be effectively decreased by giving oral sodium phytate. This has been

been sound rather than spectacular The safety regulations under Clause 1 and any orders extending the scope of the Bill under Clause 17 would be subject to an affirmative-resolution procedure, as also any orders made under the new clause for preventing overlapping with the Factories Acts He had no illusion that by passing the Bill Parliament would automatically achieve its objectives Everything would depend upon the regulations This task would be undertaken in earnest and every effort would be made to ensure that the regulations should be effective and sensible

QUESTION TIME

Registration of Medical Auxiliaries

In answer to a question Miss PATRICIA HORNSBY SMITH, parliamentary secretary to the Ministry of Health, said that the Minister did not propose to publish the report of the working party set up to inquire into the possibilities of State registration of medical auxiliaries, since it was prepared for confidential circulation only He was considering the views of all the bodies concerned and hoped to make a further statement soon

Obituary

WILFRID PATON PHILIP

M C , M B Aberd , Hon M A Camb , D M R E , D P H

FOR 36 years, until his retirement last year, Dr Paton Philip had been responsible for the tuberculosis services of the county, city, and university of Cambridge He will be especially remembered as a pioneer in the use of X rays, for he was one of the first to appreciate the value of the proper screening of patients

He was born at Stonehaven and he studied medicine at the University of Aberdeen After graduating M B in 1912 his first posts were in Merseyside where he served as house officer in the Stanley Road Hospital, Liverpool, and later as assistant tuberculosis officer and bacteriologist at Bootle During the 1914–18 war he served with the R A M C and won the Military Cross Soon after demobilisation he went to Cambridge, at first as assistant medical officer at Papworth Village Settlement In 1919 he succeeded Sir Pendrill Varrier-Jones as tuberculosis officer to the county A few years later he began to use X rays for diagnosis, and G L C recalls how "in those difficult days of administrative control by small and poor local government authorities, Philip's first apparatus in the then tuberculosis dispensary was bought out of his own pocket—and he was an Aberdonian" In 1929 he took the D M R E and in 1931 the D P H

He renewed his early association with Papworth when he became physician to the settlement, and his special interest in preventive medicine and in diagnosis was of great value to the Cambridge University Health Service With the establishment of the National Health Service he became consultant in chest medicine to the East Anglian Regional Hospital Board and he was also consultant chest physician to the United Cambridge Hospitals In recognition of his work the university in 1950 conferred on him the honorary degree of M A , and in the same year he was elected a fellow of the American College of Chest Physicians Two months ago, soon after his retirement, his colleagues and associates in teaching gave him a presentation 'in token of their gratitude and affection"

A L B writes "Philip was by nature an artist, with all the advantages and some of the disadvantages of the artistic temperament There can be few physicians in the long history of medicine who were so well beloved as he was by his patients and his fellows He had, like all great clinicians, that sixth sense which led him to the true heart of a difficult case The mere words 'P P does not think so' were enough to dispose of alternative diagnoses He was a big man physically, of striking appearance, and always well dressed His emotions were easily aroused, and it could be an embarrassment to walk down King's Parade with him while he discussed, with a wealth of gesture, some rare case His temperament was such that he found official rules and regulations particularly irksome, and the unfortunate officials whose duty it was to administer them sometimes felt the weight of his anger His oratory on such occasions was impressive For a long time I represented 'the Ministry' in his mind and so I, perhaps better than most men, can pay tribute to his selflessness In all the years I knew him he never sought anything for himself, other than recognition of the importance of the work on which he was engaged and proper provision for this It was fortunate that in the latter years of his life, when his clinical skill and wisdom were at their peak, he was given membership of the University, consultant status in the National Health Service, and an in-patient unit of his own I think that he would have agreed that the last ten years were the happiest of his professional life Now it has ended, and we in Cambridge mourn the loss of a man who did so much to maintain the reputation of medicine and the standing of the physician"

Dr Philip leaves a widow two sons, and a daughter

NORMAN DARROCH BEGG

M D Aberd , D P H

Dr Norman Begg, director of the European region of the World Health Organisation, died in London on May 23, after a short illness, at the age of 49 At the closing meeting of the World Health Assembly in Geneva a tribute was paid to his work

He was born of Scottish parentage at Kuling, China, and educated in Aberdeen, where he graduated M B in the University in 1929 He took the D P H in 1932 and joined the fever-hospital service of the London County Council in 1934 at the North-Eastern Fever Hospital A year later he went to Southend-on-Sea as medical superintendent of their fever hospital where he also acted as epidemiologist on the staff of the medical officer of health and was much in demand for domiciliary consultation In 1937 he returned to the L C C service as medical superintendent of the Eastern Fever Hospital at Homerton As with other London fever hospitals, a section was set aside for air-raid casualties The district was heavily bombed on many occasions and Begg faced courageously and with conspicuous success the many demands on his administrative and clinical skill

From the early days of the war he had applied repeatedly to be allowed to join the medical services of the Armed Forces, but he was required to continue his civilian work In 1945, however, when the air-raids on London ceased he was permitted to accept an invitation from the United Nations Relief and Rehabilitation Administration to work in Poland His secondment was in the first place for one year, but it was extended year by year until 1948 when the fever hospitals were transferred to the regional hospital boards Shortly before this Begg had been appointed medical superintendent of the North-Eastern Fever Hospital, but he never took up the post, and in 1948 he resigned from the hospital service to accept an appointment with W H O which had just been established He remained in Poland for some time and was later appointed chief of W H O 's special office in Europe, with responsibility for the reconstruction of the health and hospital services in the war-devastated countries of Europe After the decentralisation of the work of W H O into regions in 1951 he was appointed director of the regional office for Europe, which included several countries in North Africa and the Near East His post was one of the most difficult in public-health administration Most countries in the region are not like those in other parts of the world, preoccupied with the need to obtain outside assistance in developing health services from an existing rudimentary level Each has already reached a high level of development in health work, their future advance cannot be based merely on the lessons of experience elsewhere It was the recognition of this that led him to plan a European programme which differed sharply from the activities in other regions It was characterised by cooperative activities from which the health workers of many countries benefited, rather than assistance which benefited only a particular country It concentrated especially on the interchange and spreading of knowledge and practice within Europe, and the international seminars, which were a prominent

MANAGEMENT OF "IDIOPATHIC" HYPERCALCÆMIA IN INFANCY

THOMAS STAPLETON
D M Oxfd, M R C P
ASSISTANT DIRECTOR, PÆDIATRIC UNIT

W B MACDONALD
M D Melb, M R A C P
LECTURER IN PÆDIATRICS

REGINALD LIGHTWOOD
M D Lond, F R C P
DIRECTOR, PÆDIATRIC UNIT

ST MARY'S HOSPITAL MEDICAL SCHOOL, LONDON

THE purpose of this paper is to record the management of an infant with "idiopathic" hypercalcæmia by means of a diet which was almost free of calcium The results of this trial not only confirm that such treatment may restore the raised serum calcium to a normal level (Creery and Neill 1954, Ferguson and McGowan 1954, Russell et al 1954, Stapleton and Evans 1955, Bonham Carter et al 1955, Macdonald and Stapleton 1955), but also demonstrate the possibility of reversing certain of the cardiovascular and renal changes in the severe grades of the disorder

Case-report

A male infant was born three weeks after the expected date, weighing 5 lb 10 oz Labour was induced, but was uncomplicated His mother had had no added vitamins during her pregnancy There was one sibling, a healthy girl aged 3 years

The infant was breast fed for six weeks From the age of 18 days he received a complement of 1 fluid ounce of reconstituted half cream National dried milk (containing not less than 280 I U vitamin D per dried ounce) to each feed At the age of 6 weeks breast feeding was discontinued and he was fed on half cream National dried milk He progressed well, physically and mentally, until the age of 8 weeks when he weighed 9 lb From this time he failed to thrive, and at the age of 10 weeks he began to vomit His feeding was changed to full cream National dried milk (containing not less than 280 I U vitamin D per dried ounce), then successively to 'Ostermilk' no 2 (containing not less than 320 I U vitamin D per dried ounce), Nestle's Sweetened Condensed Milk (containing no added vitamin D), full cream dairy milk, and half cream National dried milk He received 1 teaspoonful of orange juice per day from the age of 3 months, and for four days only he was given 2 drops of 'Radiostoleum' per day He received no other vitamin supplement Despite these changes in diet, vomiting persisted, and his weight remained about 9 lb He was constipated from the age of 3 months He took water eagerly without vomiting At the age of 3 months he was attempting to raise his head, and was grasping at objects, but from this age he became hypotonic and h neuromuscular development did not progress He wa contented baby in spite of his failure to thrive

On admission to Southend General Hospital, at the age of months, his weight was 8 lb 15 oz "Idiopathic" hyp calcæmia was diagnosed (serum calcium 14 0 mg per 100 ml On Sept 10, 1955, aged 5 months he was transferred to S Mary's Hospital for special study He was alert and co tented, but weighed only 9 lb 1 oz His muscle tone w poor, but the deep reflexes were active His appetite w poor and he was constipated His skeletal measurements a skull circumference were normal (see table) and the anter fontanelle was patent A moderately loud systolic bru which had not been recorded previously, was found T heart was not enlarged His systolic blood pressure when was quiet was 170–185 mm Hg (flush method) Radiologic examination showed no abnormality in the long bones, b in the astragalus and os calcis on each side there were peripher zones of greater density surrounding relatively transluce central cores No centres of ossification were seen in t carpal bones

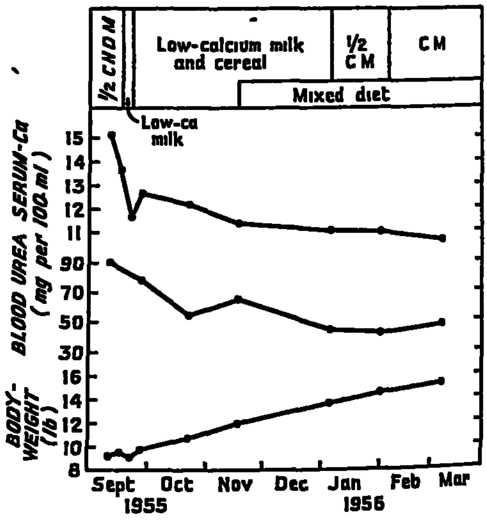

Fig 1—Treatment related to serum-calcium and blood urea levels a body weight Symbols as in table

Serum biochemistry confirmed the diagnosis of hyp calcæmia There was azotæmia and the serum alkalin phosphatase level was low (see table) There was no glyc suria, albuminuria, or amino aciduria Microscopy of t urine showed an occasional pus cell, a slight growth protous was believed to be a contaminant An electr cardiogram was normal

The sudden onset of the illness at an early age the failu to gain weight, hypertension and systolic murmur an azotæmia indicated a moderately severe grade of the disea

CLINICAL AND BIOCHEMICAL PROGRESS WITH CHANGES IN DIET, FROM TIME OF ADMISSION TO ST MARY'S HOSPIT

Date	Age (mos)	Diet	Weight (lb oz)	Length (in)	Skull circ (in)	Cardiac murmur	Systolic blood pressure (mm Hg)	Serum calcium (mg per 100 ml)	Serum phosphorus (mg per 100 ml)	Blood urea (mg per 100 ml)	Serum cholesterol (mg per 100 ml)	Serum alkaline phosphatase (K A units)

Notes and News

CHANGES IN SOCIAL RESPONSIBILITY

In a Cantor lecture to the Royal Society of Arts on May 29 Dr Roger Tredgold pointed out that some people who speak of the decline in social responsibility do so with 'righteous indignation'—a mixture of anger and self-complacency not uncommon in our society—while others are indulging in the tendency to praise the past at the expense of the present. Criticisms of this kind give pleasure to the speaker, and flatter his pride by the implication of his own admirable social responsibility, but their effects on the listener are not pleasant at all: they are accepted very seldom and acted on less.

Admittedly there are no direct statistics and no yardstick, so no final diagnosis of the situation is possible. But, in their patients' interests, doctors are often obliged to recommend some treatment before their diagnosis is final. One may indulge, therefore, in a little speculation.

Social irresponsibility, Dr Tredgold felt, occurs in two forms: (1) in people whose early upbringing is so deficient in affection that adequate social relationships cannot be formed (the antisocial psychopaths—known variously to other authorities) and (2) in those who can respond to environmental influences and in particular to the expectation in the family, at school, and in the various media of communication. The late war, for instance, showed that a changed expectation can awaken and satisfy social responsibility. The individual "has felt loyal, and been heroic." Unfortunately this expectation is now less: we have lost sight of individual responsibilities in our proper desire for individual rights. "'No rights without responsibilities' would be a better slogan than many which have won an election."

On the whole, therefore, Dr Tredgold was compelled to conclude that in this country "the responsibility of each of us for the welfare of each other citizen" is getting less. Among the reasons for this he put "the break-up of many families, the lessened skill and security of both parents and teachers, the lessened influence of the citizen who is responsible on him who is not, and conversely the greater influence of irresponsible and self-centring propaganda by press, wireless, and other means, and so the lack of expectation of responsibility in the community", and finally the misuse of leisure. These conditions, he thought, are increasing in their scope and power, and will do so faster as social irresponsibility increases. There is then a vicious spiral.

Are we, he asked, aware of this? "The majority are unaware and complacent, a minority has some vague sense of it, and is anxious and ill at ease. But this anxiety, tragically, leads to no appropriate action; indeed it does the reverse, for it may well lead, as we have seen, to criticism, anger, and superiority. And this is unlikely to cause anything but stubborn ill will, and a hardening into self-interest, self-righteousness, and perhaps a narrow loyalty to a small group." In international relations the same lack of responsibility towards other people is reflected: national interests are consistently put first, just as within nations the interests of small groups are preferred to the nation's. The truth that "charity begins at home" is often used to mean "charity stops at home."

Among the remedies he proposed Dr Tredgold put first the improvement of the quality of parenthood. "We must try to inculcate the idea that we are no more born good parents than we are born good children. We must recognise that it is a skill and not just 'mother love'; factors which influence development are there to be studied, and a skill is there to improve with practice." Secondly teachers must be selected and trained to be more secure than now, and more skilled: "can anyone feel that the average teacher's value to society is in any way reflected in his or her possible earnings?" Thirdly, the State should not financially penalise parents who want to send their children to public schools where social responsibility is taught. And fourthly, as individuals and as members of professions each must do what he can to influence public opinion, and those who mould it, so as to increase a sense of responsibility where possible—an up-hill task. "We must try to get recognised those trends which decrease responsibility in childhood, adolescence, military service, work, and leisure. But we must also ensure that this recognition does not lead to pontifical criticism." As a final slogan the lecturer suggested "No criticism without construction."

THE RIGHT SORT OF APPEAL

Mental hospitals all over the country are short of nurses, and everywhere efforts are being made to attract suitable men and women to this worth-while profession. The booklet which has lately been issued by a Birmingham hospital management committee is an example of stimulating recruiting technique. *The Story of Mental Nursing and of Rubery Hill and Hollymoor Hospitals* shows the variety of work in a mental hospital today. As the well-chosen illustrations make clear, the hospital itself is a complex organisation run by a mixed team including doctors, nurses, tradesmen, typists, and therapists. It is also backed by the mental health services of the city of Birmingham which offer aftercare to the patient who has returned to his home. The booklet thus shows a community doing its best to deal with a community's problem: it is a persuasive appeal to others to share this responsibility.

FAMILY PLANNING ASSOCIATION

At the annual general meeting of this association on June 2 Sir Russell Brain, P.R.C.P., was elected president in succession to the late Lord Horder. Addressing delegates from more than 200 branches Sir Russell said: "It seems to me that there can be few Associations in existence which have such opportunities of contributing to human happiness as this, and I mean that in two senses, the happiness of the individual in contributing to the security of happy married life, and in the broader sense of human welfare. I believe that we are faced at present, with a crisis in the evolution of the human race, and unless we can solve the population problem the consequences will be really disastrous." Mrs Pandit, the High Commissioner for India, who also spoke, said that in India the problem was not one of propaganda but of machinery and of the need for a simpler contraceptive. Each State now had a long-term programme; though population must go on increasing before this could have any effect, at least a start had been made.

HOME FOR HANDICAPPED WOMEN

The Oxfordshire branch of the British Red Cross Society has opened a home for physically handicapped women, aged 16–40, at Andrew Duncan House, Shiplake, near Henley-on-Thames. Admission is on medical recommendation, but mental defectives or those with fits or incontinence are not accepted. The cost is 5 guineas a week. Full information can be obtained from the County Civilian Welfare Officer, British Red Cross Society, 101, Banbury Road, Oxford.

APPROVED NAMES FOR DRUGS

The British Pharmacopœia Commission has issued the following supplementary list of approved names:

Approved name	*Other names*
Chlorotrianisene	Tri-(p-methoxyphenyl)-chloroethylene Tri-p-anisylchloroethylene TACE
Edetic Acid	Ethylenediamine tetra-acetic acid
*Levorphanol	(−)-3-Hydroxy-N-methylmorphinan Levorphan Dromoran is the tartrate
Mephentermine	N, α, α-Trimethyl-β-phenylethylamine Mephine
Meprobamate	2-Methyl-2-propyl-1,3-propanediol dicarbamate Equanil, Miltown
Mercaptopurine	6-Mercaptopurine Puri-nethol
Methyprylone	3,3-Diethyl-5-methylpiperidine-2,4-dione Noludar
Nitrofurantoin	1-(5-Nitro-2-furfurylideneamino)hydantoin Furadantin
Nystatin	An antibiotic produced by *Streptomyces noursei* Mycostatin
Phensuximide	N-Methyl-α-phenylsuccinimide Milontin
Pyridostigmine	3-Dimethylcarbamoyloxy-1-methylpyridinium Mestinon is the bromide
Sodium Calciumedetate	Calcium chelate of the disodium salt of ethylenediamine tetra-acetic acid

* Replaces levorphan as the approved name.

AMENDMENTS

The approved name methœstrol is withdrawn and the entry under promethœstrol amended as follows:

Promethœstrol	3,4-Di-(4-hydroxy-3-methylphenyl)-hexane Methœstrol

atrioventricular valves (Hjelt et al 1956), it certainly may occur in the absence of hypertension The fall in the blood-pressure in the present case and the disappearance of the murmur in this and in one other of our cases emphasise the value of early treatment Possibly other features of the severe cases are reversible, as well as preventable, by prompt and early treatment

Summary

A case of "idiopathic" hypercalcæmia of infancy was treated with a low-calcium diet

The blood-pressure, which had been raised, reverted to normal and a cardiac murmur disappeared

The advantages of treatment with a low-calcium diet, including a low-calcium cereal, are discussed

Criteria for deciding when to allow the infant to return to a normal diet are suggested

We wish to thank Dr R H Dobbs and his colleagues at Southend General Hospital for allowing us to investigate and treat this case, and Mr I W J Evans who carried out many of the analyses and prepared the charts The blood-urea, serum cholesterol, and alkaline phosphatase estimations were made in the department of chemical pathology, St Mary's Hospital We are grateful to Dr W F J Cuthbertson (Glaxo Laboratories) for especially preparing the low calcium cereal The balance studies would not have been possible without the enthusiastic help of Sister M S Anderson and her staff

TREATMENT OF AMŒBIASIS WITH RESOTREN

L Pfannemueller

M D

SPECIALIST IN INTERNAL AND TROPICAL DISEASES, GERMAN RED CROSS HOSPITAL, PUSAN, KOREA

CLINICAL studies on 'Resotren'* by Halawani et al (1951), Mohr (1953), Chaudhuri et al (1954), Knorr (1954), Sarsam (1954, 1955), and Scheel (1955) cover more than 300 cases The various reports agree that resotren is effective in both intestinal and extra intestinal amœbiasis

Resotren is a chemical combination of chloroquine and iodohydroxyquinoline and, taken by mouth, is poorly absorbed and reaches the lower bowel in considerable concentration Fuhrmann and Koenig (1953), who studied its pharmacology, report that about half of it is gradually broken down in the small intestine, releasing chloroquine and iodohydroxyquinoline, which are then absorbed The remainder passes into the large intestine, where some is also split up, and thus both chloroquine and iodohydroxyquinoline are brought to the site of infection, where they never are present in such amounts when given separately by mouth

I review here 42 cases seen while I was physician to the Mosul and Hillah hospitals in Iraq These cases are summarised as follows

Type	*No of cases*	*Results**	*Remarks*
Uncomplicated amœbic dysentery	5	Clinical cure and negative stools within 8 days in all patients	No relapses, 3 cases previously treated with aureomycin without permanent success
Amœbic hepatitis complicating amœbic dysentery	31	Clinical cure in 30 (1 did not complete course) negative stools in 29	Rapid disappearance of hepatomegaly in [illegible] cases regression of symptoms and liver enlargement within two days 14 in which amœbic hepatitis had developed after treatment elsewhere with aureomycin rapidly responded to resotren
Liver abscess complicating amœbic dysentery	6	Clinical cure and negative stools in all	Acute severe cases all rapidly responded to resotren without surgery 1 case was 'needled' [illegible] 150 ml of chocolate coloured pus In the first two or three days chloroquine was given additionally

* Search for *Entamœba histolytica* in the stools during six months after treatment gave negative results

Clinical Studies

Uncomplicated Amœbic Dysentery

The first 3 cases included in the table were of typical acute uncomplicated amœbic dysentery with bloody diarrhœa and positive stools The first 2 had been treated with aureomycin elsewhere and relapsed, the 2nd patient had a black hairy tongue due to the antibiotic All 3 patients were rapidly cured with resotren, the clinical symptoms disappearing by the third day Neither trophozoites nor cysts could be found in the stools at the end of the course or during the follow up

Cases 4 and 5 were of chronic uncomplicated amœbic dysentery with only cysts in the stool Both patients were cured of their clinical symptoms by the end of the course, cysts were no longer present in the stool, and the stools were negative during the six-month follow up

Amœbic Hepatitis Complicating Amœbic Dysentery

31 cases of amœbic hepatitis were treated with resotren In all the cases amœbæ or cysts were found in the stools, but, in view of the positive clinical signs present in each case, their absence would not have altered our diagnosis The liver was palpable and generally enlarged to three finger-breadths below the costal margin, and pain on pressure was a constant finding

Treatment with resotren produced striking improvement in all the cases, the liver returned to its normal size and the symptoms disappeared, in some cases within four days of the start of treatment In 2 cases cysts were still present in the stools at the end of treatment, 2 other patients were not examined at the end of the course owing to factors outside our control The remaining 27 had negative stools after treatment, 14 of them had previously been treated elsewhere with the broad spectrum antibiotics, aureomycin or oxytetracycline, before they came to this hospital

Liver Abscess Complicating Amœbic Dysentery

6 cases of acute amœbic liver abscess were treated with resotren Results were excellent, the clinical symptoms rapidly disappeared, and the stools became negative both for trophozoites and cysts by the end of the course The temperature returned to normal, usually by the third day of treatment, and radiography before and after treatment confirmed the impressive clinical effect of resotren

DOSAGE

Usually a course of resotren consisted of 40 tablets given as follows

1st day	3 × 2 tablets	= 6
2nd–5th day	4 × 1 tablet	= 16
6th–10th day	3 × 1 tablet	= 15
11th–12th day	3 × 0 5 tablet	= 3
12 days		40

---

* Resotren is a product of Farbenfabriken Bayer A -G, Leverkusen, Germany

PASSION AND CONTROVERSY IN SCIENCE *

MICHAEL POLANYI
M D Budapest D Sc Princeton D Sc Leeds F R S
PROFESSOR OF SOCIAL STUDIES IN THE UNIVERSITY OF MANCHESTER

My title may sound shocking for the first thing you know about science is that it is dispassionate Science is said to describe *facts* which are there whether you like them or not facts derived from the experience of *things* that can be seen and touched Scientific knowledge is therefore regarded as matter-of-fact, impersonal objective in sharp contrast to our moral convictions, religious beliefs, and other persuasions that are charged with emotion

The father of empiricism, John Locke, has said that whatever is not capable of demonstration by experience 'is not unless it be self evident capable to produce knowledge how well grounded and great soever the assurance of faith may be wherewith it is received , but faith it is still and not knowledge , persuasion and not certainty '[1] How then can passion ever participate in producing knowledge ? How can it indeed do aught but adulterate objective demonstration by an admixture of unwarranted persuasion ?

Yet there is on record the overwhelming elation felt by scientists at the moment of discovery, elation of a kind which only a scientist can feel and science alone can evoke in him Kepler testified to it in his *Harmonices Mundi*, published in 1619, in which he announced the discovery of his Third Law,' connecting planetary periods and distances He writes

> nothing holds me I will indulge my sacred fury , I will taunt mankind with the candid confession that I have stolen the golden vases of the Egyptians in order to build of them a tabernacle to my God far indeed from the bounds of Egypt If you forgive me I shall rejoice , if you are angry, I shall bear it the die is cast the book is written whether to be read now or by posterity I care not it may wait a hundred years for its reader if God himself has waited six thousand years for a man to contemplate His work '

We have the image of Archimedes jumping out of his bath to rush through the streets of Syracuse shouting Eureka ! And we have it on record how Louis Pasteur rushed out likewise from his laboratory when he first separated lævo and dextro rotatory tartrates and fervently embraced the laboratory assistant in the corridor

The outbreak of such emotions in the course of discovery is well known but they are not thought to affect the outcome of discovery Science is regarded as objectively established in spite of its passionate origins But in my title I mentioned passions *in* science and I do actually want to show that scientific passions are no mere psychological by-play, but have a logical function which contributes an indispensable element to science They respond to an essential quality in a scientific statement and may accordingly be said to be right or wrong depending on whether we acknowledge or deny the presence of that quality in it

What is this quality ? Passions charge objects with emotions making them repulsive or attractive , positive passions affirm that something is precious The excitement of the scientist making a discovery is an *intellectual* passion, telling that something is *intellectually* precious and, more particularly, that it is *precious to science* And this affirmation forms part of science The words of Kepler which I quoted were not a statement of fact but neither were they merely a report of Kepler's personal feelings They asserted as a valid affirmation of science something else than a fact namely, the scientific interest of certain facts the facts just discovered by Kepler. They affirmed indeed that these facts are of immense scientific interest and will be so regarded so long as knowledge lasts Nor was Kepler deceived in this majestic sentiment The passing centuries have paid their cumulative tribute to his vision, and so I believe, will the centuries yet to come

The function which I attribute here to scientific passion is that of distinguishing between demonstrable facts which are of scientific interest, and those which are not And hence also of serving as a guide in the assessment of what is of higher and what of lesser interest what is great in science and what relatively slight I want to show that this appreciation depends ultimately on a sense of intellectual beauty , that it is an emotional response which can never be dispassionately defined, any more than we can dispassionately define the beauty of a work of art or the excellence of a noble action

It is true that the scientific value of an observation usually increases with its generality But unique facts may also possess profound scientific significance Take Tycho Brahe's discovery of a nova a new fixed star in 1572 or the synthesis of urea by Wohler in 1828 The great scientific value of these discoveries lay in the fact that they fundamentally changed our conception about the nature of things The birth of Tycho's new star proved that the empyrean was subject to change Its occurrence invaded the last area of the universe still reserved to the rule of divine principles and annexed it to the realm of accident and necessity a fit subject of empirical science By this discovery Tycho anticipated Newton's demonstration that the same laws governed the stars in their courses and the swing of a clock's pendulum Similarly, Wohler by his synthesis of urea broke through the barrier between the inanimate and the living He proved that no 'life-force" was required for the production of organic matter, and thus opened the path to biochemistry

Discoveries like those of Tycho or Wohler are valued for the breadth of their implications even though they establish no new general laws They offer something more vague and also more profound namely, a truer understanding of a large domain of experience. Generality is indeed but an aspect of profundity in science and profundity itself as we shall see but an expression of the feeling that we are making a new more intimate contact with reality

* * *

The following case of scientific glory blighted by the later progress of science will illustrate this point In 1914 T W Richards, then professor of chemistry in Harvard, was awarded the Nobel prize for his determination of some atomic weights with an accuracy far surpassing that which had been achieved before His results have never been contested But in 1932 Frederick Soddy could write of this type of measurement that it appears now of as little interest and significance as the determination of the average weight of a collection of bottles some of them full and some of them more or less empty For it had been realised that the value of atomic weights resulted from the accidental proportion in which the constituent isotopes happen to be present in the element as found in Nature A magnitude that had seemed to characterise a deep seated feature of the universe had turned out to have no such bearing Though factually correct it had proved deceptive because—contrary to expectation—it did not correspond to anything substantial in Nature When the exact atomic weight of an element had ceased to be of interest to science, what had seemed important had turned out to be trivial

[1] Locke J Third Letter on Toleration

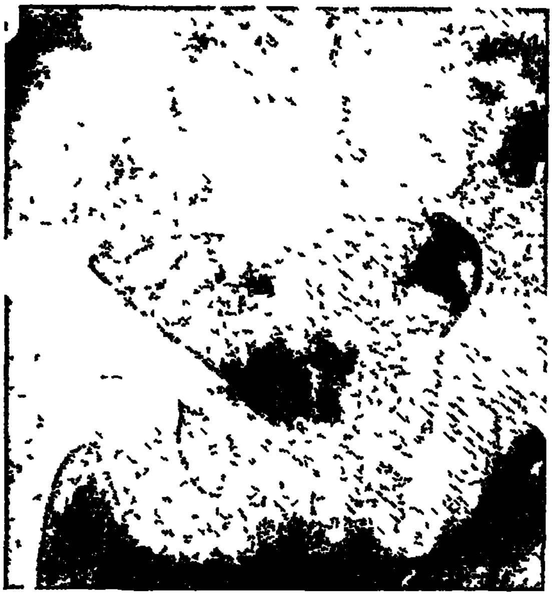

Fig 1—Pelvis (Oct 14, 1954) showing fractures of all pubic rami with gross deformity

Her sternal marrow was normoblastic, with no evidence of carcinoma, myeloma, or leukæmia Her blood contained protein 6 4 g per 100 ml (A G ratio 1 8 1), sodium 320 mg per 100 ml, potassium 15 mg per 100 ml, chloride 610 mg per 100 ml, CO_2 combining power 55 vol %, urea 30 mg per 100 ml, calcium 10 1 mg per 100 ml (average of 8 readings), phosphorus 2 7 mg per 100 ml (average of 8 readings), alkaline phosphatase 28 units, serum bilirubin 0 4 mg per 100 ml, thymol turbidity 2, gold sol test negative, glucose (fasting) 120 mg per 100 ml, and amylase 100 Somogyi units

Glucose tolerance test—The blood sugar level was 90 mg per 100 ml fasting, and at 30 minute intervals after 50 g of glucose 210, 150, 90, and 60 mg per 100 ml, her urine after 30 and 60 minutes contained a trace of sugar, but later specimens contained none

Urine—No albumin, Bence Jones proteoses, red cells, pus cells, or organisms, only occasional traces of sugar, 17 ketosteroids 6 7 mg in 24 hours (average of 3 readings), calcium (on ordinary ward diet) 69 mg in 24 hours (average of 4 readings), and phosphorus 460 mg in 24 hours (average of 4 readings)

Fæcal fat (estimated over a 3 day period after 6 days on a fixed daily intake of 30 g of fat)—Average daily fæcal

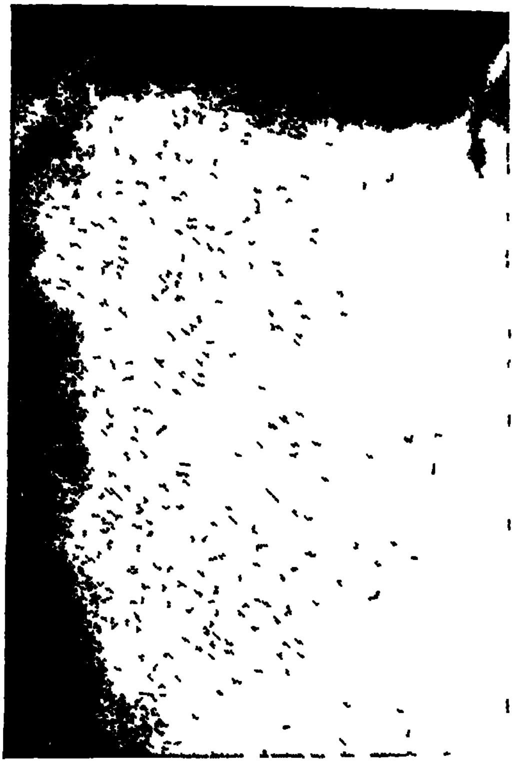

Fig 2—Right 10th, 11th, and 12th ribs (Oct 14, 1954) showing unheal fractures with excessive callus

fat was 18 4 g (only 63% absorption of fat) Of fæcal f 66% was split and 34% unsplit

Test meal—Complete achlorhydria Jejunal secretio contained trypsin and lipase

Radiography of skeleton (figs 1–5)—The pelvis showed striking "squash in" deformity with widely distributed an ill defined patches of decalcification All *four* pubic ra showed unhealed fractures Fifteen ribs were fractured in the lower ribs these fractures were more prominen unhealed, and surrounded by excessive callus Symmetrica false fractures were seen in the lateral borders of both scapul and the lower ends of both fibulæ The long bones showe generalised and somewhat patchy decalcification The vaul of the skull also showed patchy ill defined areas decalcification

Intravenous pyelography showed no renal abnormality

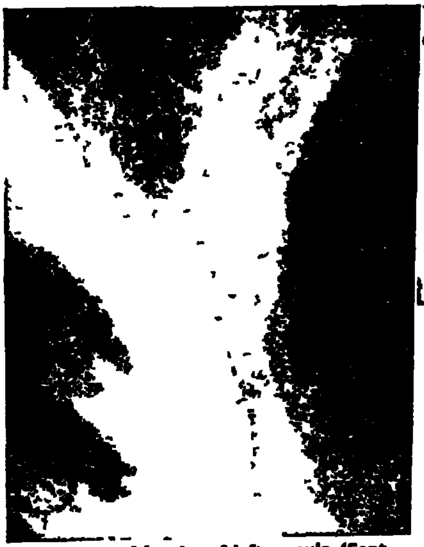

Fig 3—Lateral border of left scapula (Sept 6, 1951) showing Looser s zone

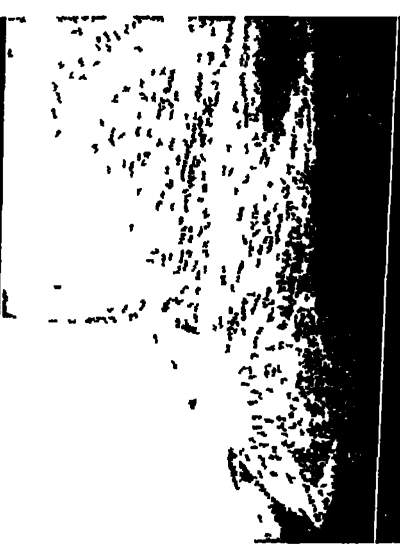

Fig 4—Lower end of left fibula (Oct 14 1954) showing Looser s zone and fracture

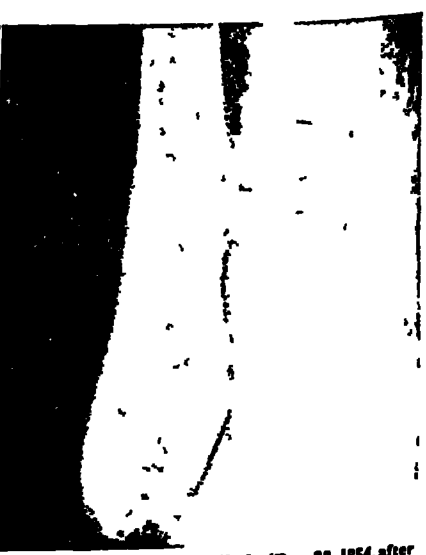

Fig 5—Lower end of right fibula (Dec 29 1954, after six weeks' treatment) showing healing of old Looser's zone and fracture

But this passionate quest seeks no personal possession Intellectual passions are not like appetites, they do not reach out to grab, but set out to enrich the world Yet such a move is also an attack It raises a claim and makes a tremendous demand on other men, for it asks that its gift—its gift to humanity—be accepted by all In order to be satisfied, our intellectual passions must find response This universal intent creates a tension We suffer when a vision of reality to which we have committed ourselves is contemptuously ignored by others For a general unbelief threatens to evoke a similar response in us which would imperil our own convictions Our vision must conquer or die

Like the heuristic passion from which it flows, the *persuasive passion* too finds itself facing a logical gap To the extent to which a discoverer has committed himself to a new vision of reality, he has separated himself from others who still think on the old lines His persuasive passion spurs him now to cross this gap by converting everybody to his way of seeing things, even as his heuristic passion had spurred him to cross the heuristic gap which separated him from discovery

We can now see the great difficulty that may arise in the attempt to persuade others to accept a new idea in science To the extent to which it represents a new way of reasoning, we cannot convince others of it by formal argument, for so long as we argue within their framework we can never induce them to abandon it Demonstration must be supplemented therefore by forms of persuasion which can induce a *conversion* The refusal to enter on the opponent's way of arguing must be justified by making it appear altogether unreasonable

Such comprehensive rejection cannot fail to discredit the opponent He will be made to appear as thoroughly deluded, which in the heat of the battle will easily come to imply that he was a fool, a crank, or a fraud And once we are out to establish such charges we shall readily go on to expose our opponent as a metaphysician, a Jesuit, a Jew, or a Bolshevik, as the case may be, or—speaking from the other side of the Iron Curtain—as an "objectivist," an "idealist," and a "cosmopolitan" In a clash of intellectual passions each side must inevitably attack the opponent's person

* * *

I shall recall here three controversies to illustrate this They occurred in the 19th century and their outcome has had an effective part in developing our present sense of scientific value

The first of these conflicts, though brief, was momentous The quixotic attack of the young Hegel on the empirical method of science and his swift defeat at the hands of the scientists was one of the great formative experiences of modern science In the year 1800 a band of six German astronomers, led by Bode, set out to search for a new planet to fill a gap between Mars and Jupiter in the numerical series of planetary distances discovered by Titius, and known as Bode's law The series is obtained by writing down the number 4, followed by the series $3 + 4, 2\ 3 + 4, 2^2\ 3 + 4, 2^3\ 3 + 4$ &c This gives for the first eight places 4, 7, 10, 16, 28, 52, 100, 196, which can be shown to correspond pretty well to the relative distances of the six planets known in 1800, provided you leave out the fifth number Setting the distance of the Earth arbitrarily at 10 you have the table

Bode's law

	Predicted	*Observed*		*Predicted*	*Observed*
Mercury	4	4	?	28	?
Venus	7	7	Jupiter	52	52
Earth	(10)	(10)	Saturn	100	95
Mars	16	15	Uranus	196	192

The young Hegel poured scorn on an inquiry following up a regularity of numbers which, being meaningless, could only be accidental On the grounds that Nature, shaped by immanent reason, must be governed by a rational sequence of numbers, he postulated that the relative spacing of the planets must conform to the Pythagorean series 1, 2, 3, 4 (2^2), 9(3^2), 8(2^3), 27(3^3)—in which, however, he substituted 16 for 8 This would limit the number of planets to 7, and allow a large gap between the 4th and 5th planets, i e Mars and Jupiter The quest for an eighth planet to fill this gap was therefore nonsensical[3]

However, on Jan 1, 1801, Bode's party of astronomers discovered the small planet Ceres in the region in question Since then over 500 small planets have been found in that neighbourhood,[4] and it may be that these are fragments of a full sized planet that took this place before

Hegel was discomfited and the astronomers triumphed uproariously This was all to the good, for it confirmed a juster sense of scientific value But we should realise that it had little else to support it Whether Bode's law has any rational foundation or has been fulfilled so far by mere coincidence (as Hegel had thought) is still open to question today opinions have changed on the subject repeatedly during the past fifteen years[5] So Hegel may have been right in rejecting the astronomers' grounds for their search for a new planet

Yet I agree that the astronomers were right and Hegel was wrong Why so? Because the astronomers' guess lay within a conceivably scientific system and so it was a kind of guess to which astronomers as scientists are entitled It was a *competent* guess, and—if Bode's law has any truth in it—even a true guess, while Hegel's inference was altogether unscientific, *incompetent* Fortunately Hegel guessed wrong and the astronomers, though their guess was perhaps unjustified, did hit the mark But even if Hegel's guess had proved right and the astronomers' wrong, we would still reject Hegel's vision of reality and cleave to that of the astronomers

In any case, the revulsion of scientists against *Naturphilosophie* was violent and lasting By the middle of the century empiricism ruled unchallenged But unfortunately the empirical method of inquiry—with its associated conceptions of scientific value and of the nature of reality—is far from unambiguous, and consequently conflicting interpretations of it had ever again to fight each other from either side of a logical gap

In his doctoral thesis, presented in 1875 to the university of Utrecht, J H van t'Hoff had put forward the theory that compounds containing an asymmetric carbon atom are optically active In 1877 there appeared a German translation of this work with a commendatory introduction by Wislicenus, a distinguished German chemist and an authority on optical activity This publication evoked a furious attack from Kolbe, another leading German chemist, who had recently published an article called Signs of the Times,[6] in which he castigated the decline of rigorous scientific training among German chemists, a decline which, he said, had led to a renewed sprouting of

"the weeds of a seemingly learned and brilliant but actually trivial and empty Philosophy of Nature, which, after having

---

[3] Hegel Dissertatio philosophica de Orbitis Planetarum (1801) Werke Berlin 1834, vol 16, p 28
In his lectures on the Philosophy of Nature Hegel admitted the presence of Ceres and other asteroids in this gap He still referred to the numbers of the Timaeus but he now declared that the law of the planetary distances was still unknown and that one day the scientists would have to turn to the philosophers to find it Bertrand Beaumont in discussing Hegel's position (*Mind* 1954 63, 246) suggests that the Platonic series could be extended beyond the original seven, but in terms of Greek mathematics this is impossible

[4] Turner H H Astronomical Discovery London 1904, p 23

[5] An attempt to interpret Bode's law rationally by deriving it from a theory of the planetary system was made by C F von Weizsäcker in 1943 (*Z Astrophys* 1944 22 319) But from a later paper it appears that the problem is still in flux (see C F von Weizsäcker, Festschrift der Akademie der Wissenschaften in Göttingen, 1951, p 120)

[6] Kolbe, A W H *J prakt Chem* 1877, 14 268

Case-report

A 21 year old woman, mother of two children aged 21 months and 11 months, was admitted unconscious from another hospital on July 22, 1955 The patient's husband had left her in apparently normal condition at 6 P M the previous day When he returned at 9 P M he found her lying unconscious face down on the floor, a douche can containing a soapy solution and a syringe beside her There was no unequivocal evidence that she had actually used these Before the patient was admitted to hospital at 11 15 P M the same night she vomited several times

On admission the patient was unconscious, with eyes deviated to the left and pupils reacting briskly to light The upper limbs were hypertonic and held in flexion, the lower limbs were flaccid with absent tendon reflexes and extensor plantar responses She was about five months pregnant There was a slightly bloodstained discharge from the vagina, the external os of the uterus was closed Urine obtained by catheter contained a trace of albumin The stomach was washed out, nothing abnormal was found in its contents The next day the temperature had risen to 101 8°F, large doses of penicillin were administered During the day she remained unconscious and exhibited twitchings of the left upper limb Intracerebral hæmorrhage or air embolism following a mechanical attempt to produce abortion was suspected, and the patient was transferred to the Department of Surgical Neurology, Royal Infirmary, Edinburgh

On examination twenty-four hours after she had been found unconscious, the woman was still unconscious but moaned and became restless in response to painful stimuli Only the upper half of the body took part in the restlessness, and such response was elicited only by painful stimuli to the face, upper limbs, and trunk, there was no response to pinching or deep pin pricks applied to the lower limbs There was irregular twitching of both upper limbs, which were intensely hypertonic and were held adducted at the shoulder and flexed at the elbow, while there was obviously flaccid paralysis of the lower limbs with extensor plantar responses and retention of urine There were no signs of meningeal irritation Pupillary reactions were normal, the eyeballs were not deviated, and the eyegrounds were normal Lumbar puncture yielded clear cerebrospinal fluid containing 6 cells per c mm and 260 mg of protein per 100 ml, the colloidal gold curve was normal and the Wassermann reaction negative, the fluid mechanics were normal The cervix uteri now admitted three fingers and products of gestation could be palpated

Course —During the subsequent night the patient had a complete spontaneous abortion and the temperature returned to normal Twelve hours after admission re examination showed a sensory level for painful stimuli on the right side at T2, and on the left side at T4 There was no change in the level of consciousness, irregular twitching in the upper limbs continued, and other findings were unchanged Ascending neuronitis of the Landry type due to apiol poisoning with toxic coma and convulsions, was tentatively diagnosed Efforts to find any published suggestions as to the treatment of this condition were unsuccessful, so symptomatic treatment was applied Breathing remained satisfactory and nursing in the respirator appeared unnecessary

Sixty hours after admission the sensory level had risen to T1 bilaterally Twitching was now observed also in the face, otherwise the neurological condition was unchanged Urinary excretion remained satisfactory, and subsequent specimens of urine contained no albumin Absorption of the tube feeds was normal The patient died eighty four hours after she had been found, without regaining consciousness

After her death, the patient's husband admitted that he had seen "black pills, like 'Beecham's pills'" in the vomited matter A neighbour had cleaned the floor after the patient's removal to hospital, and no pills or container were found in the house

Pathological Findings

Post mortem examination showed no external injuries No abnormality of the *cardiovascular system* was seen on naked eye examination, and in particular there was no evidence of air embolism Microscopically there were several minute foci of myocardial necrosis with early polymorph infiltration The *lungs* were congested with early bronchopneumonic consolidation The *gastro intestinal tract* was healthy The *liver* appeared normal on external examination histologically there was minimal focal necrosis of liver cells The *spleen and pancreas* were normal The *kidneys* were completely normal both on naked eye and on microscopic examination The uterus showed evidence of recent, complete abortion There was no evidence of artificial stripping of the membranes or of other trauma to the uterus, vagina, or external genitalia

The *brain* showed slight generalised swelling with compression of both lateral and third ventricles, but no other gross abnormality The meninges, superficial cortical vessels and arteries forming the circle of Willis were healthy Histologically focal necrotic lesions were scattered throughout the brain In these damaged zones there was necrosis of nerve cells and to a lesser extent of neuroglia There was pallor of staining and vacuolation of ground substance with patches of early polymorph cell infiltration and proliferation of microglia with, in some instances, foam cell production In lesions in white matter the axons were swollen These foci of early necrosis affected grey matter more than white matter and cortex rather than subcortical grey matter They did not appear to follow any special anatomical distribution, nor were they necessarily related to blood vessels, though a causal relationship to small arterioles and capillaries could not be entirely excluded since in some instances there was quite distinct endothelial swelling and hyperplasia The leptomeninges overlying damaged areas of cortex showed scanty infiltration with foam cells and mononuclear cells Apart from the vascular changes already described the blood vessels were normal

In the *spinal cord* the 6th, 7th, and 8th cervical and the 1st thoracic segments were swollen, and during removal of the cord the partly liquefied 7th cervical segment disintegrated so that no material from this segment was available for histological examination Sections from the remaining cervical and from dorsal and lumbar segments of the cord showed foci of necrosis in the anterior grey horns identical with the lesions in the brain No abnormality of white matter, meninges, or blood-vessels was seen

Peripheral nerves —Numerous sections were examined from the ulnar, popliteal, and femoral nerves on each side, but despite staining by various methods, no evidence of peripheral neuritis was found

Biochemical analysis of liver and kidney and of bladder and bowel contents yielded no confirmation of the presence of apiol or an adulterant thereof

The lesions in the central nervous system, liver, and myocardium were either toxic or ischæmic and were not characteristic of any infective condition

Discussion

In this case it was evident that the nervous system was diffusely affected, coma and convulsions pointed to widespread cerebral damage The rising sensory level pointed to damage of the spinal cord, peripheral nerve lesions were also suspected, but their presence was not confirmed by post mortem examination Poisoning with triorthocresyl phosphate from taking an overdose of impure apiol was thought to be the cause of the neurological syndrome It was subsequently established that apiol had been supplied to the deceased woman, but the date of supply and amount of apiol could not be ascertained

One of us had seen similar cases on the Continent where the condition had occurred among pregnant women, intent on abortion, who had taken large doses of apiol preparations or so called "female pills" Most of the patients referred to in Continental reports developed weakness and tingling in the periphery of the lower limbs followed by similar symptoms in the upper limbs Some patients developed the syndrome of ascending myelitis or Landry's paralysis The symptoms began usually one to three weeks after the apiol preparation had been taken, irrespective of whether abortion had occurred

Extensive chemical investigations and subsequent animal experiments (ter Braak and Carillo 1932) proved that apiol itself was not responsible for the neurological illness Like other volatile oils, apiol—if taken in excessive doses—produces severe gastro intestinal irritation for Mendelism on the grounds that "in science there is no place for chance".[14]

There are serious questions still open today concerning the nature of things—at least, I believe them to be open, though the great majority of scientists are, as usual, convinced that the view which they hold is right and they meet any challenge to it with scorn. A notorious example is extrasensory perception. The evidence for it is ignored today by scientists in the hope that it will one day find some trivial explanation. In this they may be right; but I respect those too who think they may be wrong. And no profitable discussion is possible between the two.

Another example. Neurologists today accept almost without exception the assumption that all conscious mental processes can be interpreted as epiphenomena of a chain of material events in the nervous system. Some writers, like Prof K W Kapp, have tried to show that this is logically untenable, and I myself believe he is right. But to my knowledge only one neurologist—namely, Prof J C Eccles—has gone so far as to amend the neurological model of the brain by introducing an influence by which the will intervenes to determine the choice between possible alternative decisions.[15] This suggestion is scornfully ignored by all other neurologists, and indeed it is difficult to argue profitably about it from their point of view.

A similar schism is present today between the ruling school of genetics, which explains evolution as a result of a haphazard sequence of mutations, and writers such as Graham Cannon in England, Dalcq in Belgium, and Vandel and others in France, who consider this explanation inadequate and support the assumption of a harmonious adaptive power controlling the most important innovations in the origin of phyla.

* * *

Some people may listen to these illustrations with impatience for they believe that science provides a procedure for deciding any such issues by systematic and dispassionate empirical investigations. However, if that were clearly the case, there would be no reason to be angry with me. My argument would have no persuasive force, and could be ignored without anger.

At any rate, let me make quite clear what I have urged here. I have said that intellectual passions have an affirmative content; they affirm the scientific value of certain facts, as against any lack of such interest in others. This *selective* function—in the absence of which science could not be defined at all—is closely linked to another function of the same passions in which their cognitive content is supplemented by a conative component. This is their *heuristic* function. The heuristic impulse links our appreciation of scientific value to a vision of reality, which serves as a guide to inquiry. Heuristic passion is also the mainspring of originality—the force which impels us to abandon an accepted framework of interpretation and commit ourselves, by the crossing of a logical gap, to the use of a new framework.

Finally, heuristic passion will often turn (and have to turn) into *persuasive* passion, the mainspring of all fundamental controversy. I am not advocating the outbreak of such passions. I do not like to see a scientist trying to bring an opponent into intellectual contempt, and to silence him in order to gain attention for himself; but I acknowledge that such means of controversy may be tragically inevitable.

I certainly affirm that passion, and controversy moved by passion, must continue in science. And I would add to this my belief that, if this amendment to our conception of science be accepted, it would have to be followed by others which would lead to a fairly comprehensive revision of our philosophy of science.

PÆDIATRIC PHYSICIAN, DUNDEE ROYAL INFIRMARY

WE report here the results of metabolic balance studies on 2 infants with idiopathic hypercalcæmia and the effects of treatment with cortisone. One of these infants was also treated with disodium ethylenediamine-tetracetic acid (E D T A) during the metabolic studies.

Cortisone and corticotrophin have been shown to increase fæcal calcium and to lower a raised serum-calcium level in Cushing's syndrome (Soffer et al 1950), rheumatoid arthritis (Kinsell et al 1950, Moehlig and Steinbach 1954) and sarcoidosis (Shulman et al 1952, Dent et al 1953, Henneman et al 1954). The efficacy of cortisone in lowering the serum calcium level and relieving the symptoms of 4 infants with idiopathic hypercalcæmia has now been reported (Creery and Neill 1954a, Macdonald and Stapleton 1955). This action of cortisone is as little understood as the pathogenesis of idiopathic hypercalcæmia, and the present studies were an attempt to investigate both problems.

Case-reports

Case 1.—A girl, born on Dec 25, 1953 at full term after a normal delivery, weighed 6 lb. Both parents were aged 26 and healthy. The mother had been well during pregnancy and had taken the usual supplements of vitamins. The baby was breast fed till the age of 9 weeks, when the supply failed and she was put on dried milk ('Lactogen,' Nestle). At the age of 6½ months her diet was changed to 2 pints of full cream National dried milk daily. Mixed feeding was started when she was 5 months old. She had been having up to half a teaspoonful of National cod liver oil compound daily (400 I U of vitamin D) between the ages of 1 and 6 months. At the age of 8 months she was admitted to Dundee Royal Infirmary on Aug 23, 1954, under the care of one of us (J T) because for six weeks she had not been taking her feeds well. She had vomited occasionally and three weeks before admission she had vomited all feeds for a week. Scanty stools were passed twice daily.

On admission she weighed 11 lb 5 oz but appeared well nourished. She was small, bright and interested, and slept well. She had prominent epicanthic folds and paresis of both external recti muscles. A systolic murmur of moderate intensity took the place of the first sound all over the precordium; it was maximal at the pulmonary area and was transmitted to the left axilla. No thrill was felt. The blood-pressure at a single reading was 174/110 mm Hg. The history of bottle feeding, loss of appetite, vomiting, and constipation, and the cardiac murmur suggested idiopathic hypercalcæmia.

Investigations.—Electrocardiography showed no prolongation of the P–R interval. The urine was usually acid and contained no protein or sugar and only a few pus cells. Mantoux tests to 1/100 were negative, and radiography of the whole skeleton, heart, and lungs, and iodised oil given by mouth showed no abnormality. Radiographically there was no calcification in the kidneys. The plasma calcium level was 16.8 mg per 100 ml and the blood urea level 135 mg per 100 ml. Other biochemical findings are shown in table I and fig 1.

Treatment and progress.—Two weeks after admission a low calcium diet of breast-milk treated with disodium E D T A

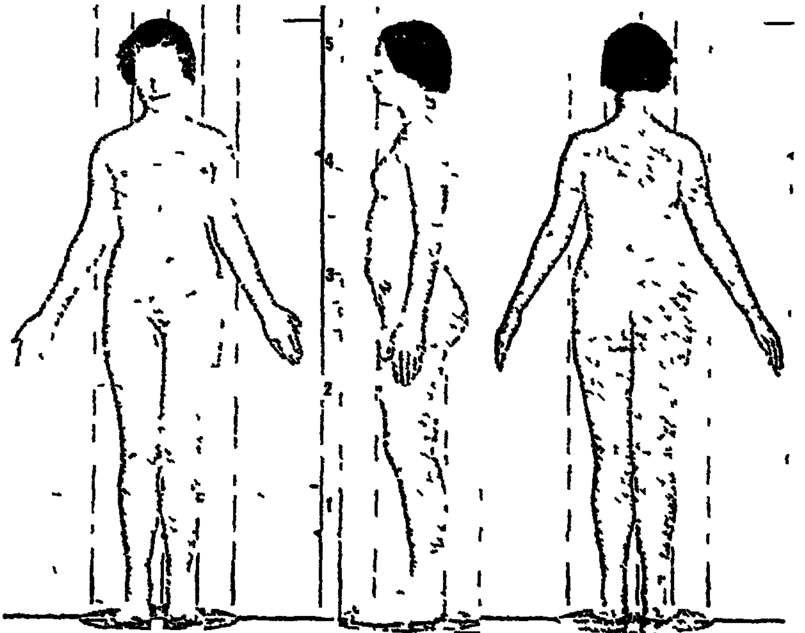

Fig 2—The patient three years after irradiation of her pelvis

Radiotherapy—Three days later the child was transferred to St Bartholomew's Hospital, under the care of Mr I G Williams, and a course of X ray therapy was given to her pelvis A total depth dose of 2150r was given in thirty days by anterior and posterior fields (fig 1) measuring 14 × 12 cm, at 250 kV peak, 60 cm focus skin distance, half value layer 1 75 mm Cu During the course she had an attack of left sided abdominal pain with some muscle guarding This subsided after three days without intervention Her hæmoglobin decreased from 72 to 58% by the end of the treatment, but her white cell count always remained over 5000 per c mm At the end of the treatment the tumour could not be felt per rectum The girl was returned to the Hospital for Sick Children, where her anæmia was corrected by blood transfusion

At a second laparotomy (Mr D I Williams) on Oct 3, 1952, the right ovary, on release from its protective sheath looked healthy and was returned to the pelvis The left ovary, with its sheath, had escaped from the suture to the abdominal wall and had ulcerated into the wall of the pelvic colon, causing a pericolic abscess and fistula The abscess was drained and, to rest the damaged gut while the fistula healed, a transverse colostomy was done This was closed by Mr Twistington Higgins on Nov 26, 1952, when an examination of the child's pelvis revealed no tumour in the sacrococcygeal region

Histology—Dr Martin Bodian reported that the tumour was a neuroblastoma showing very little evidence of differentiation

Follow up—It is now three years since the tumour was treated The patient is 11 years old, weighs 8 st, and is 5 ft 2 in tall She is in good health, her bowel and bladder functions are normal, and there is no clinical evidence of any tumour in the pelvis Her physical development is proceeding naturally (fig 2) She began to menstruate in November, 1954 when she was 10½ years old and now has a regular cycle of twenty eight days

Discussion

Three years after treatment for a pelvic neuroblastoma, with no sign of recurrence of the tumour, the prognosis for life is likely to be good

It remains to be seen what damage has been done by the treatment, in particular damage to the ovaries by the irradiation Since the menarche cannot be established without a functioning ovary, one at least of our patient's ovaries must be virtually intact

The doses of X rays received by the two ovaries differed As can be seen from fig 1, only one ovary was within the beam of the X rays The dose received within a lead sheath of similar dimensions to those used was recently measured, and from these measurements it has been calculated that the left ovary received about 170r during the treatment and the right ovary about 50r

It is known that temporary sterility can be achieved in the adult by 170r in a single dose, and that ovulation ceases after 290r (single dose) The dose received by our patient's left ovary would probably correspond to less than 70r given at one time, and is therefore below the threshold for damage to ovarian function

How much harm has been done to her fertility and what genetic damage has been caused, it is impossible to say at present, but some mutations are almost certain

Summary

A heavy dose of X rays to a malignant tumour was prevented from having a lethal effect on a child's ovaries by fixing lead sheaths round them and by removing the ovaries from the direct beam of X rays

The lead was removed after the course of irradiation, and three years later there was evidence of ovarian function

We are indebted to Mr Twistington Higgins and Mr I G Williams for permission to publish, Dr W M Levitt and Mr D I Williams for help in the management of the patient, Dr Martin Bodian for the histology report, Mr G S Innes for measuring the dose of X rays received, and Mr T C Crichton for constructing the original shells

EUNUCHOIDISM

RESPONSE TO VERY LATE TREATMENT WITH TESTOSTERONE

S G FLAVELL MATTS
M B Birm
RESIDENT MEDICAL OFFICER, ROYAL DEVON AND EXETER HOSPITAL

A BUSINESS man, aged 40, first seen in late 1951, complained of extreme depression, shyness and feeling of inferiority, lack of energy, muscular weakness, lack of interest in life, and absence of all secondary sexual characteristics

He was the youngest of a family of 5 his brother and 3 sisters were all normal and were all married, with children His childhood was normal, with no serious illnesses His left testis had always been present in his scrotum, but his right testis was undescended, and puberty had never occurred He had never had any trace of secondary sexual characteristics, any facial hair, or any evidence of sexual activity

At the age of 20 he had a discharge from his umbilicus, and a patent urachus was diagnosed and removed

At the age of 25 he had consulted an endocrinologist who diagnosed 'Pituitary dyscrasia with cryptorchidism' and treated it at first with '*orchitic substance*" and later with injections of chorionic gonadotrophin ('Antuitrin S') The injections apparently produced effects growth of pubic hair, penile erection for the first time in his life (without discharge) improvement in his facial skin, and increase in the size of his right testis, which could be manipulated into the scrotum temporarily He continued with the injections for twelve months without further effects No secondary sexual characteristics developed, and he became disheartened discontinued treatment, and regressed to his previous condition He was morose, shy, lonely, had no ambition, had very severe feelings of inferiority, and could not mix with other people He also had periodic attacks of extreme depression lasting several days in which he lost all interest in life He had no sexual feelings, was afraid of women, and had no intention of marrying

On examination he was very obese (weight 13 st, height 67 inches) with striking feminine distribution of fat about his lower abdomen, thighs, hips, and breasts (extreme gynæco

Further course.—On Dec 10, 1954, the urine, which had never been quite free from pus cells, contained much pus, and two specimens grew proteus, a further course of streptomycin was given, and the pyuria disappeared On Dec 29, 1954, diarrhœa developed and the boy rapidly became dehydrated. His urine again contained pus and proteus sensitive to streptomycin. Three specimens of stool were free from pathogens The plasma-calcium level was 10·1 mg per 100 ml, but the blood-urea level had risen to 95 mg per 100 ml and the plasma-phosphorus level to 6·4 mg per 100 ml Intravenous fluid and electrolytes followed by a transfusion of 150 ml of blood produced rapid recovery, and by Jan 3, 1955 he was beginning to sit up again and to take solid food, although he was still a little subdued. During the night he became extremely ill and died suddenly and unexpectedly on Jan 4 at the age of 1 year

Necropsy (Dr K. Rhaney) revealed gross foci of calcification in the outer part of the renal medulla, with virtually none in the cortex or in the distal pyramids Large thrombi, possibly of embolic origin, were present in many of the pulmonary arteries within the lungs, these thrombi showed different stages of organisation, and the oldest had clearly been present for a week or more There were no pulmonary infarcts Further lesions revealed by histological examination, were acute bronchiolitis, early bronchopneumonia, and mild enteritis There was no other metastatic calcification The immediate cause of death appeared to be the acute bronchopneumonia in the presence of severe pulmonary arterial occlusion The importance of the primary disease could not be assessed in relation to the other causes of death. Full details of the necropsy will be reported elsewhere (Rhaney and Mitchell 1956)

Methods

A metabolic bed was used during the balance studies Fæces dropped directly into waxed cardboard containers Urine was collected through a plastic appliance (designed by Mr D Munro, L D S, of Dundee Dental Hospital) in the case of the female infant and through Paul's tubing strapped to the penis in the case of the male infant

Significant vomiting took place only once during the balance studies (period IV, case 2), and the estimated loss was subtracted from that day's intake

The diet in case 1 consisted of fresh cow's milk thickened with corn-flour (because of its small content of calcium), and in case 2 of fresh cow's milk in periods

TABLE II—BALANCE FINDINGS IN CASE 1

Period	Therapy	Calcium (mg daily)						Phosphorus (mg daily)					
		Excretion			Diet	Balance	Absorption (%)	Excretion			Diet	Balance	Absorption (%)
		Fæces	Urine	Total				Fæces	Urine	Total			
I (Nov 3–6)	Nil	382	55*	437	899	+462	57·5	168	181	349	648	−299	74

* Excluding loss of not more than 5% of total urine volume

absorbed was 20% less The urinary output of calcium remained large Despite this greater retention of calcium the plasma calcium level remained just over 12 mg per 100 ml For eleven days before and during period IV the dosage of cortisone was halved to 12 5 mg daily, even more calcium was retained, and the plasma calcium level rose to 17 2 mg per 100 ml After a return to the original dosage of cortisone the level again fell Further clinical improvement allowed the introduction of a more mixed diet containing less calcium, and in period V calcium and phosphorus were both in balance under treatment with only 12 5 mg of cortisone daily In comparison with the control period when the calcium and phosphorus intakes were similar, this strikingly different result was clearly due to the increased fæcal output of calcium and phosphorus

The urinary output of calcium remained large throughout periods II–IV despite varying plasma calcium levels but decreased in period V, possibly owing to the virtual lack of absorption of calcium The amount of urinary phosphorus also decreased considerably in period V, again possibly owing to the large amount of fæcal phosphorus

Oral disodium EDTA in case 1 seemed to lower plasma-calcium levels a little on both occasions when it was tried The object was to produce a low calcium diet very simply by adding EDTA powder to milk, because this substance chelates calcium into a soluble, non-ionised, and therefore biologically inactive, compound which is virtually unabsorbed from the gut (Foreman and Trujillo 1954) However, EDTA binds only a tenth of its weight of calcium, and 10 g would have been necessary to produce a calcium free diet on cow's milk, although only about 4 g on breast milk Unfortunately, loose stools developed as a toxic effect whenever the daily intake exceeded 2 g Disodium EDTA was also given subcutaneously (over period II) to combine with the calcium in the body-fluids and thus to reduce the toxic plasma calcium level, since 95% of intravenous calcium EDTA has been shown to be excreted in the urine in twenty four hours (Foreman and Trujillo 1954) The daily dose was 1 g in 100–200 ml of N/5 saline solution, given over four hours The object was to assess its efficacy in treating acute hypercalcæmic episodes No local ill effects appeared The plasma-calcium level fell to normal but rose again the day after the administration was stopped The urinary excretion increased considerably, but not quite to the extent expected from the dosage

Discussion

Incidence

During the two years ending Oct 1, 1955, 15 children with hypercalcæmia were treated in the pædiatric units of Dundee hospitals This condition accounted for 4 6% of all medical admissions of children aged 6–12 months, and ranked fourth in frequency after respiratory infections, feeding difficulties, and otitis media This number represents the approximate incidence of diagnosed cases in a population of 450,000 Idiopathic hypercalcæmia is also a significant cause of death, 4 of these infants died

Ætiology

Theories of causation have to explain not only the hypercalcæmia, with its consequent anorexia and vomiting, but also the spontaneous improvement shown by most of these infants An explanation should be provided too for the apparent increase in incidence in the United Kingdom in the past few years

The ætiological rôle of alkaline medication was suggested by Creery (1953), who noted the clinical resemblance to the "milk and alkali" syndrome of adults (Burnett et al 1949), because a large proportion of the diets of these infants consisted of cow's milk Creery and Neill (1954a), however, conceded that a history of taking alkalis in the form of either magnesium hydroxide or alkaline carminatives was not obtainable in all cases We also have seen hypercalcæmic infants who have not been given any alkali Alkalis cannot therefore be more than a contributory factor

The significance of a large intake of calcium is much more definite, in all the published cases the infants have had either fresh or reconstituted cow's milk They have thus had to contend with intakes of calcium and phosphorus about five times as great as would have been obtained from the same volume of human milk However it is of particular interest that one of our other hypercalcæmic patients was still being breast-fed when the diagnosis was made at the age of 8 months, and only a small amount of cow's milk had been given in milk puddings and with other cereal foods This infant had never been given dried milk but had had one teaspoonful of National cod-liver oil compound (vitamin D 800 I U) daily from the age of $4^{1}/_{2}$ months Cow's milk therefore appears to be a factor in the causation of the syndrome but other factors must exist because idiopathic hypercalcæmia develops in only a very small minority of the many infants who receive a similar intake of cow's milk and alkalis

Hyperparathyroidism, due to parathyroid hyperplasia rather than tumour, was one of several possibilities considered by McCance three years ago (McCance 1954) but is an unlikely explanation in view of the normal plasma-phosphorus level in the absence of severe uræmia, and the tendency to a low plasma-alkaline phosphatase level In addition, the plasma calcium level does not fall after cortisone in hyperparathyroidism (Dent 1956) whereas a striking fall occurred in our cases

Perhaps the most remarkable finding in our own and in previously published studies of the calcium balance of such infants (Creery and Neill 1954a, McCance 1954, Bonham Carter et al 1955) is the high proportion of the dietary calcium that is absorbed—about 60% in some instances This immediately suggests overaction of vitamin D as the probable cause, since this vitamin has the distinctive property of increasing the absorption of calcium from the gut The healthy infant fed on cow's milk without added vitamin D absorbs up to 35% of the calcium ingested (Telfer 1922), if vitamin D is added the absorption of calcium may reach 50% of the intake (Stearns 1931) but is usually less (Jeans et al 1936, Holmes 1945)

Some form of vitamin D has been used as a supplement to the diet in all the cases of idiopathic hypercalcæmia of infants that we have seen, yet in some cases the dosage does not appear to have been excessive Accurate assessment of intake of vitamin D is difficult because so many of the proprietary foods contain it, but, if dried milk fortified with vitamin D, cereals fortified with vitamin D, and the National cod-liver oil compound supplied free are all given to an infant aged 5 months, the total daily intake of vitamin D may easily exceed 2000 I U Such amounts may well be toxic (Jeans and Stearns 1938, Berry et al 1955), and the 2 infants reported here received amounts of vitamin D which were at or near these levels Other infants, however, have developed hypercalcæmia while receiving much less vitamin D, therefore, if vitamin D was the cause of the hypercalcæmia, these babies must have been unduly sensitive to its action (Lowe et al 1954)

The medium in which vitamin D is given may affect the strength of its action, Lewis (1935) reported that calciferol given in milk was several times more potent than when given in corn oil Thus the fortification of milk with vitamin D may be a method of intensifying the vitamin's action (Supplee et al 1936) It has also been

TABLE V—REPRESENTATIVE SOURCES OF VITAMIN D IN THE DIETS OF INFANTS

Food	*Vitamin D content* (I U)
Human milk	5 to 115 per quart
Fresh cow s milk	3 to 50 per quart
Evaporated milk (' Carnation ')	500 per reconstituted quart
* National dried milk	" Not less than ' 1400 per reconstituted quart
* ' Lactogen ' (Nestlé)	1500 per reconstituted quart
* ' Ostermilk (Glaxo)	1600 , ,
* Cow and Gate milk	1600 , , ,
Scott s Midlothian Oat Flour ' (M O F)	600 per oz dry weight
Robinson s Patent Groats '	800 , ,
Farex ' (Glaxo)	1000 , , ,
National cod liver oil compound	Not less than ' 700–800 per teaspoonful
Haliverol ' (Parke Davis & Co)	6000 per gramme

* The vitamin D content of dried milks may in fact be considerably higher than is stated on the label because it is incumbent on the manufacturer to produce a product of not less than the stated level and he has to allow for possible losses in processing or during the period between production and retail sale

done successfully in sarcoidosis with hypercalcæmia (Henneman and Carroll 1955) but we cannot yet confirm its efficacy in idiopathic hypercalcæmia

Prevention

The evidence cited leads us to believe that vitamin D is the most significant factor in the development of hypercalcæmia It is therefore pertinent to consider what amount of vitamin D should be recommended for infants It was conventional pædiatric practice for many years to recommend the addition of 400 I U per day to prevent deficiency, but the official recommendation in the United Kingdom has been 700 I U per day (as fortified cod-liver oil) since 1943, when the British Pædiatric Association advised an increase to ensure an ample margin of safety In the literature there is no general agreement Jeans (1950), Harrison (1954), and others (American Medical Association 1955) agree that 300–400 I U per day is enough to prevent rickets and to allow optimal growth In Sweden 1500 I U daily has been officially recommended (Mellander 1955), and yet 1800 I U daily has been recorded as causing delayed growth (Jeans and Stearns 1938) In the United Kingdom the vitamin-D intake of many infants may be even larger (table V) Although such larger amounts are usually well tolerated a few infants may show toxic effects, as there is wide individual variation in the response to vitamin D (Anning et al 1948, Bicknell and Prescott 1953) We suggest that the spontaneous improvement of idiopathic hypercalcæmia may be due to diminishing consumption of foods fortified with vitamin D in later childhood, as well as to a possible increase in individual tolerance

In the United Kingdom the question may well be posed whether more illness may now be due to vitamin D than to the rickets it is given to prevent As long ago as 1936, Thatcher expressed alarm at the potentialities then existing for the development of vitamin D intoxication in infancy, these have vastly increased in the succeeding twenty years We agree with Creery and Neill (1954b) that there is a need for reassessment of the degree of fortification of all infant foods and we feel that there should be warning labels on potent preparations of vitamin D, since few mothers are aware of the many ways in which their children may receive this vitamin

Summary

Descriptions are given of 2 infants with idiopathic hypercalcæmia, of whom 1 died Balance studies showed a large absorption of calcium This was probably due to overaction of vitamin D, although it is impossible to distinguish between the effects of overdosage and those of hypersensitivity

The symptoms are attributed to the hypercalcæmia, which may also damage the kidneys The plasma-calcium level can be reduced by a low-calcium diet without added vitamin D, and more rapidly by giving cortisone in addition

Cortisone increases the proportion of fæcal to dietary calcium and phosphorus and may also redistribute calcium within the body

Disodium E D T A will also reduce the plasma calcium level but has toxic effects

The considerable fortification of many infant foods in the United Kingdom undoubtedly increases the risk of hypervitaminosis D

We are grateful to Prof J L Henderson for permission to study case 2 Professor Henderson, Prof A C Lendrum, and Prof I G W Hill for criticism of the manuscript , Dr S G F Wilson for help with case 1 , Dr C E Dent for helpful advice , Sister M D Crichton and Sister E A Birnie for supervising the balance studies , and Miss M R Haslock B SC , Miss K MacKay, B SC , and Miss L Constable, B SC for technical assistance Riker Laboratories Ltd provided the E D T A A grant for apparatus was provided (to H G M) through the Advisory Committee on Medical Research (Scotland)

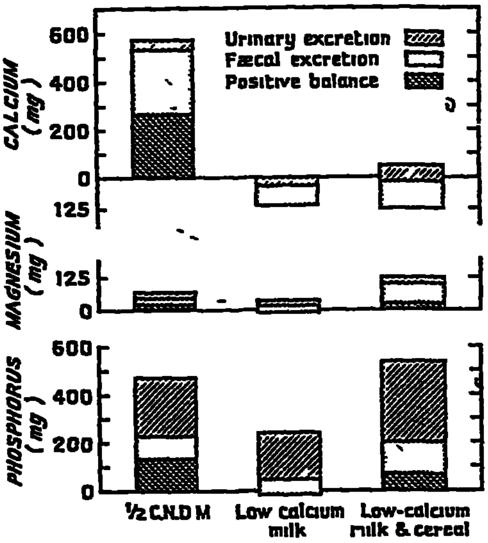

Fig 2—Treatment related to daily calcium, magnesium and phosphorus balances, which are averages of four-day collections Symbols as in table.

Before the low calcium diet was started and when the patient was taking half cream National dried milk (average daily intake of calcium 580 mg vitamin D not less than 600 I U daily) a four day balance study was done (fig 1) The balance was repeated (1) when the patient was taking Locasol,' a low-calcium milk (average daily intake of calcium less than 50 mg , no vitamin D) , and (2) when a low calcium cereal was added to the low-calcium milk (average daily intake of calcium less than 50 mg , no vitamin D) This cereal increased the caloric intake , it also had a high inorganic phosphate and phytate content

The clinical and biochemical progress of the infant is recorded in the table and fig 2 There was a steady weight-gain dating from the change in diet Vomiting ceased abruptly and he became less constipated Within a month the systolic murmur became inaudible and the blood pressure fell

After treatment for two months when he was aged 7 months vegetables cooked in distilled water and egg yolks, were added to the low calcium diet A further six weeks later the use of distilled water in preparing the feeds was discontinued and a milk mixture consisting of whole cow's milk and low-calcium milk in equal amounts was given The range of solid foods was increased, avoiding only those fortified with vitamin D

The child continued to improve skeletal and skull growth progressed at normal rates , muscle tone became normal and activity vigorous At the age of 9 months he was attempting to sit up , his mental development appeared normal , the changes in the tarsal bones shown on previous radiological examination had diminished. At the age of 11 months he weighed 15 lb 4 oz

Discussion

The Balance Studies

The balance studies were carried out (1) before treatment was started , (2) after one week on a low-calcium milk , and (3) after a further three weeks during which time a calcium-free cereal had been added to the diet (fig 1) The balances of calcium, phosphorus, magnesium, sodium, potassium, chloride, and nitrogen were measured over four-day periods Except for the calcium and phosphorus balances, no significant difference was found between the balances in the three periods, those for magnesium, sodium potassium, chloride, and nitrogen being approximately in equilibrium It was felt that these balances not only demonstrated that there was no overt upset in the metabolism of these substances, but also confirmed the accuracy of the collections during the four-day periods

The calcium balance was strongly positive during the active stage of the condition before treatment started It became negative when the infant was on low-calcium milk but there was a slightly greater fæcal excretion when the low-calcium cereal was also being taken

Management

Although some infants with hypercalcæmia recover slowly without special treatment recovery can be accelerated by giving a diet low in calcium or by administering cortisone Thus three aspects of the management call for comment the choice between a low-calcium diet or cortisone to reduce the calcium absorption and hence the serum calcium level , the advantages of a low-calcium cereal in addition to a low calcium milk , and the criteria for deciding when the child can safely return to a normal diet Our conclusions are based on the results in nine cases treated at St Mary's Hospital during the past two years

Low calcium diet or cortisone —The disadvantages of cortisone are that it has other effects than those required, in particular increasing the dangers of intercurrent infections and that short courses of treatment with cortisone are not satisfactory because, on discontinuing the cortisone the serum calcium rebounds to a high level (Macdonald and Stapleton 1955) The merit of the cortisone method of treatment is that it is simple and does not require the use of distilled water for the preparation of the feeds Small doses of cortisone are probably adequate if they are given over long periods (Creery and Neill 1954, Morgan et al 1956) It may sometimes be advisable to give a short course of cortisone at the start of a low-calcium diet if the serum calcium is very high since cortisone may cause a more rapid fall in serum-calcium than diet alone

The disadvantage of the low calcium diet is that the preparation of the low-calcium milk and cereal requires the use of distilled water It is not yet known whether using low-calcium dried milk and cereal, prepared with ordinary tap-water which may contain considerable amounts of calcium, would be satisfactory during the initial stages of treatment The advantage of the low-calcium diet is that so far as is known it is adequate in all other respects and does not have the hazards which are associated with the use of cortisone

Low-calcium cereal —The advantages of adding the low-calcium cereal to the diet of low-calcium milk are that it has a higher caloric value so that weight gain is better (and this may be an important factor in accelerating cure if calcium utilisation improves) that the high phytate and inorganic phosphorus contents may increase the loss of calcium in the fæces by binding calcium in the intestinal secretions (Bonham Carter et al 1955, Macdonald and Stapleton 1955), and that it provides a food suitable for older infants For infants who are entirely bottle-fed, it can be added to the milk in small amounts (up to a drachm per ounce has been found satisfactory)

Duration of treatment —The criteria used to decide when it is wise to return to a normal diet are a return of the serum calcium to normal , a fall in the blood-urea to normal (unless this occurs it is probable that the previous high serum-calcium has led to irreparable kidney damage [Lowe et al 1954, Schlesinger et al 1956]) , a rise in the serum alkaline-phosphatase , and a steady gain in weight None of these criteria is reliable by itself

The disappearance of the cardiac murmur and the lowering of the raised blood-pressure are of great interest, since these signs are usually found only in the more severely affected infants (Lightwood and Stapleton 1953, Lowe et al 1954, Schlesinger et al 1956) Some observers do not consider that the severe and the simple forms of the condition are distinct because their experience includes many cases intermediate between the simple and the severe ones showing only a few of the features of the severe cases (Lightwood 1955, Lightwood et al).

The nature of the cardiac murmur is not clear In some instances it may be due to actual calcification in the

If the initial condition of the patient was very severe, or if the case was of long duration a further course of 20 tablets in four days was given eight days after the first course If an acute liver abscess was present with serious symptoms, chloroquine was given in addition to resotren for the first two or three days

SIDE EFFECTS

Resotren was well tolerated The blood-count erythrocyte-sedimentation rate, and analysis of urine in all the cases showed no deviation from normal during treatment No alteration of the buccal or intestinal flora, such as is seen with the antibiotics, was noted during treatment with resotren The commonest side effect was initial diarrhœa This may not be a disadvantage, for some workers recommend an initial purge to remove the amœbæ from the lacunæ of the bowels If the diarrhœa was severe, the dose was reduced for a few days, and this was sufficient to stop this side effect

Discussion

The liver is involved in more cases of amœbic dysentery than is generally realised 10–20% has been given as the prevalence of amœbic hepatitis, and more than half the cases of chronic amœbic dysentery give abnormal liver-function tests (Mazzitelli 1954) Any treatment of amœbic dysentery which ignores this fact is not sound The development of amœbic hepatitis or liver abscess either during or after treatment of amœbic dysentery with a broad-spectrum antibiotic has already been reported by McHardy and Frye (1954) and Scaffidi and Sangiorgi (1952) The fact that 14 of the present cases had relapsed with hepatic amœbiasis after treatment elsewhere of amœbic dysentery with either aureomycin or oxytetracycline emphasises that treatment of the dysenteric symptoms alone is insufficient

The requisite drug should act both intestinally and extra-intestinally This means that it must be absorbed high in the intestine and concentrate in the liver, yet remain in the lumen of the gut and act against the trophozoites in the lacunæ of the large intestine Resotren seems to be able to do this Clinically it is effective in acute amœbic dysentery, chronic dysentery, and the hepatic manifestations of amœbiasis Its effect on liver abscess is dramatic, and none of the cases reported here required surgery, even though they were severe One case was "needled" to free about 5 oz of pus

Summary

42 cases of amœbiasis, including 31 of hepatitis and 6 of liver abscess, were treated with resotren

All forms of amœbiasis responded to resotren Clinical cure was achieved in all the cases, and at the end of treatment the stools were negative for both cysts and vegetative forms in 40 of the 42 cases

In cases of severe liver abscess chloroquine was given in addition to resotren on the first two or three days

Treatment with broad-spectrum antibiotics does not appear suitable in 14 of the present cases amœbic hepatitis had developed after treatment elsewhere with such antibiotics

OSTEOMALACIA FOLLOWING GASTRECTOMY

L N Pyrah
M Sc, Ch M Leeds, F R C S
PROFESSOR OF UROLOGICAL SURGERY IN THE UNIVERSITY OF LEEDS

Irvine B Smith
F R C S

Although steatorrhœa may follow gastrectomy and steatorrhœa may lead to osteomalacia, in clinical practice osteomalacia must be very rare as a complication of gastrectomy, so the present case is worth recording

Case-report

A married woman, aged 52, attended the General Infirmary at Leeds on April 24, 1954, with recent severe backache Later, as a result of investigations and the discovery of a previous breast biopsy report, she was referred to one of us (L N P) for advice about bilateral adrenalectomy for supposed bone metastases complicating a possible carcinoma of the breast This diagnosis was not accepted, and the patient was readmitted to hospital on Oct 4, 1954, for review and further investigation By this time she had been taking stilbœstrol 5 mg thrice daily for three months

History—Her childhood had been healthy, with no suggestion of rickets, cœliac disease, or other serious illness At the age of 18 she began to have indigestion with epigastric pain and vomiting, from which she obtained partial relief by the use of a suitable diet, olive oil, and alkalis Eight years later she made a rapid recovery from an operation for acute appendicitis with pelvic peritonitis When she was aged 33 (in 1935), a perforated chronic gastric ulcer was sutured A month after this a biopsy specimen of a lump in her left breast was reported to show "chronic mastitis with evidence of considerable epithelial proliferation producing small papillomata in some ducts, but no definite evidence of malignancy" While taking the prescribed diet she remained fairly well for the next five years, but in 1940 severe epigastric pain developed, and a barium meal showed a chronic gastric ulcer with an hour glass deformity On March 11, 1940, Mr E R Flint did a partial gastrectomy with a Polya Moynihan anastomosis, the patient recovered well and was not seen again for seven years When questioned later, she admitted that she usually had two rather loose stools daily In 1947, at the age of 45, she was readmitted to hospital with severe microcytic anæmia (Hb 28%, red cells 2,380,000 per c mm, colour index 0 5) She had complete achlorhydria, and her bowels were loose but not unduly active After treatment with iron and hog's stomach, her Hb increased slowly to 86% At this time she first noticed pain in her left shoulder, and radiography of her cervical spine was reported to show minimal osteo arthritis During the next two years her shoulder pain grew worse, she began to complain of increasing backache, and the anæmia reappeared By 1950, just after the menopause, she had almost continuous severe backache with much tenderness over her vertebral column, she began to drag her right leg, and her husband had to help her into and out of chairs and bed In 1951 her symptoms grew worse, and pain radiated from her back to her right loin and thigh, she had dorsal kyphosis, and radiography of her chest showed several fractured ribs, her anæmia had also recurred In April, 1954, while walking, she was suddenly immobilised by very severe backache and was taken home by ambulance, the pain now radiated round both sides of her trunk and was made worse by coughing

Physical examination in May, 1954, showed a small frail woman, 4 ft 8 in tall and weighing 5 st 6 lb, she had once been 4 ft 11 in tall and had weighed 7 st 2 lb She had pallor, koilonychia, well marked dorsal kyphosis, and tenderness over many ribs and her wrists and ankles, which were not swollen Her breasts showed no evidence of carcinoma Nothing abnormal was found in her abdomen, pelvis, or nervous system

Investigations

Blood examination showed Hb 51%, red cells 3,000,000 per c.mm, colour index 0 85, white cells 7200 per c mm, and erythrocyte sedimentation rate 3 mm in 1st hour (Wintrobe)

Biopsy of right eleventh rib (Oct 12, 1954).—Histologically this was a healing fracture which showed remodelling of well formed bony trabeculæ. The spaces between the trabeculæ contained loose fibrous tissue in which there were some osteoclasts. A few small areas of necrosis were present in the bone. The rib structure on either side of the fracture appeared normal, and no evidence of carcinoma or myelomatosis was seen in the marrow spaces. The appearances were not pathognomonic but were consistent with pre-existing osteomalacia in the fracture area although there was no evidence of bone disease or osteitis fibrosa cystica.

Diagnosis

The radiographic appearance of the skeleton, showing generalised decalcification, deformity of the bony pelvis, and symmetrical false fractures, suggested osteomalacia, particularly since a review of old films showed that pathological fractures of the ribs had been present at least 5½ years before, with evidence of healing. This diagnosis was supported by the history of loss of height, indicating bone softening, and by the raised serum alkaline phosphatase level, normal serum-calcium level, and low urinary excretion of calcium. The bone biopsy added further support, though by the time this biopsy was made, the patient had already spent several weeks in hospital on a good mixed diet, stilbœstrol, and vitamin tablets, and this regime may explain the healing which by then was apparent. The finding of only 63% absorption of fat established the diagnosis of steatorrhœa, but its ætiology was not obvious at first. The absence of a history of cœliac disease was against a diagnosis of idiopathic steatorrhœa. Moreover, the general shape of the chest, which was of the adult type, did not suggest the shrunken under-developed bony thorax seen in osteomalacia secondary to steatorrhœa dating from infancy. The presence of pancreatic enzymes excluded serious disease of the pancreas. The rapid absorption of glucose did not suggest disease of the jejunum as a cause of malabsorption but conformed rather to the typical post-gastrectomy type of curve characterised by a rapid rise of the blood sugar level to a high value with attendant glycosuria, followed by an equally rapid fall even to a subnormal value, which in some cases results in late postprandial hypoglycæmia. Moreover the patient also showed other deficiency phenomena which are now recognised as late complications of gastrectomy: failure to gain weight, recurring severe microcytic anæmia, and a low serum protein level suggesting a negative nitrogen balance. It therefore seems likely that the osteomalacia was caused by steatorrhœa which in turn was attributable to the previous gastrectomy. In our hospital partial gastrectomy became the standard operation for chronic duodenal ulcer in the middle of the war period, probably about 1942; gastrectomy had been the standard operation for chronic gastric ulcer for many years before that, but such cases were less common than those of chronic duodenal ulcer. The fact, therefore, that gastrectomy had been in wide use for the past fourteen years only, may explain why no other cases of this slowly developing syndrome were noted.

Treatment and Progress

On Nov 16, 1954, the patient was placed on a daily dose of calcium lactate gr. 90 and vitamin D 150,000 units and encouraged to take extra fat contained in additional frequent small feeds throughout the day. After a month's treatment most of her backache had disappeared and her legs felt better, though she was still slow to get about. Her serum-alkaline-phosphatase level had risen to a peak of 87 units, indicating active repair of bone. After three months' treatment she could get about just as she wished, felt better in herself than she had for many years, still had a little low backache and aching ankles, and was still taking the same dose of calcium and vitamin D. Her alkaline-phosphatase level had fallen to 18 units suggesting that the bone was almost completely healed. After six months she was hard at work lifting clothes in a cleaner's shop; she was quite free from pain and was surprised to find that she could run and catch a bus. Two months later she began to complain of nausea after her tablets. Although her serum calcium level was only 9 mg. per 100 ml., the dosage was reduced to 50,000 units of vitamin D and gr. 30 of calcium lactate daily; the nausea disappeared, and she has since remained well.

Comments

Osteomalacia

Except in time of war osteomalacia is rare in civilised communities and is hardly ever due to a simple lack of vitamin D (Winston and Pendergrass 1954). It is not only usually due to steatorrhœa but also one of the most significant complications thereof. Steatorrhœa is common after gastrectomy, especially after total resection. Bone changes have been seen in gastrectomised young animals. Such changes are rare in man, presumably because gastrectomy is not usually done in adolescence. A case of osteomalacia seventeen years after gastrectomy was described by Groult (1945). The patient was a nun aged 42, with advanced skeletal changes, including extensive decalcification, codfish vertebræ, heart-shaped deformity of the pelvis, and numerous symmetrical fractures. Five years after her gastrectomy she developed arthritis with swollen painful toes, feet, and ankles. As bone and joint pains increased, kyphosis developed with loss of height, and after twelve years she was driven to bed. There is no mention of her diet or of steatorrhœa, but Groult attributed her disease to malnutrition, hypovitaminosis D, and calcium deficiency resulting from her ascetic life, her previous gastrectomy, and war-time rations. Her disabilities rapidly improved under treatment with calciferol, extra calcium, and ultraviolet light.

The present case strongly suggests that the steatorrhœa which sometimes follows gastrectomy can be bad enough to cause hypovitaminosis D with bone changes. As regards practical management, it is necessary only to implement the recommendations of Brain and Stammers (1951) that gastrectomised patients should take extra fat in frequent small meals, especially if the whole stomach has been removed. Additional calcium, vitamin D, and other fat-soluble vitamins should be given by mouth if the steatorrhœa resists treatment. If gastrectomy has to be done on a child or an adolescent, these particular hazards to general and skeletal development should be remembered.

Summary

A case is described in which steatorrhœa and severe osteomalacia developed fourteen years after partial gastrectomy.

We desire to thank Dr C. E. Dent of University College Hospital, London, for helpful criticism in the preparation of this paper and Mr J. Hainsworth for the photographs.

WE describe here a case in which a patient apparently ingested apiol, in order to procure abortion. Coma and convulsions with flaccid paraplegia ensued, and the patient died. This outcome may have been due to contamination of the apiol with triorthocresyl phosphate. The case is reported since further such cases may arise from the sale, without medical prescription, of contaminated apiol as "female pills."

and toxic effects on liver, kidneys, and heart All apiol preparations which had caused damage to the nervous system of pregnant women were found to contain tri-orthocresyl phosphate Polyneuritis and spinal cord damage was produced in animals which had been fed with triorthocresyl phosphate The neurological signs in these animals did not appear until ten to twenty days after the toxic substance had been ingested

These findings resulted in restrictions on the sale of apiol to the public, and in certain parts of Germany the pharmacist was required to ensure that his supply of apiol contained no triorthocresyl phosphate

Because there have been numerous cases in different European countries, it is unlikely that triorthocresyl phosphate was an accidental admixture in apiol preparations, possibly it was deliberately included without realisation of its dangers Triorthocresyl phosphate is not unlike yellow apiol in appearance and it is a plasticiser Liquid yellow apiol is liable to give a deposit of white crystalline apiol and to become thick and pasty in consistency An addition of triorthocresyl phosphate would serve a twofold purpose it would give added bulk where this was necessary (e g , in filling a capsule without altering the dose of apiol or affecting its appearance) and, both in the capsule and in bulk it would tend to preserve the appearance and consistency of the apiol by preventing precipitation and conversion into a paste

Most women who have had peripheral neuritis as the result of triorthocresyl-phosphate poisoning have recovered One of us (K H) recalls survival of a case of ascending myelopathy with permanent paraplegia, and a death from respiratory failure in a similar syndrome (Neither of these cases was published) Most of the victims of Jamaica-ginger paralysis—a motor neuronitis proven to be due to adulteration of ginger extract with triorthocresyl phosphate (Smith and Elvove 1930, Smith and Lillie 1931, Smith et al 1932, Ahring 1942)—have also recovered Cases of acute poisoning leading to sudden coma and convulsions with severe diffuse cerebral lesions appear to be rare Lowenberg (1938) described such a case, but he described no post-mortem examination of the spinal cord, nor was it known what dose of apiol the patient had taken

The circumstances in which our patient was found suggest that she may have taken the drug more than once, since undigested capsules were found in the vomitus when she was overcome by coma Moderate doses taken earlier than the dose which produced coma might account for the presence of well-developed flaccid paraplegia a few hours after she had brought up still undigested capsules We suggest that moderate doses of the poison produce delayed effects on the peripheral nerves and spinal cord, while large doses cause immediate cerebral damage

This is the first case of damage to the nervous system from ingestion of an apiol preparation that we have seen in twenty years of neurological practice in Edinburgh We have been unable to find any references to this subject in the British literature, and only a few American reports deal with apiol poisoning although there are many accounts of the affection of the nervous system caused by triorthocresyl phosphate as impurity of ginger extract Probably apiol has in the past been used as an abortifacient in this country, but possibly previous preparations did not contain the dangerous impurity

PROTECTION OF OVARIES FROM RADIATION

RICHARD BATTEN
F R C S
LATE REGISTRAR, BIRMINGHAM ACCIDENT HOSPITAL

D E MEREDITH BROWN
M B Lond , D M R
CONSULTANT RADIOTHERAPIST,
BIRMINGHAM REGIONAL HOSPITAL BOARD

THE sensitivity of the gonads to X rays often complicates radiotherapy, especially in the treatment of malignant disease in children In boys it is easy to protect the gonads by shielding the scrotum with lead, as is usually done in radiotherapy departments In girls it is more difficult to protect the ovaries We describe here a method of doing this

Case-report

A girl, aged 8 years, was referred to the Hospital for Sick Children, Great Ormond Street, London, in August, 1952, with twelve months history of intermittent enuresis

On examination her bladder was found to be enlarged to the umbilicus, and per rectum a soft but solid mass was felt, filling the pelvis and fixed to the sacrum There was an anæsthetic area around the anus, but no other abnormality was found She was admitted under the care of Mr Twistington Higgins with a provisional diagnosis of pelvic neuroblastoma

Treatment —Surgical removal of the tumour was planned , but, since this might be incompatible with the child s survival, plans were also made to treat the tumour with X rays Dr W M Levitt pointed out that the dose of X rays necessary to do this would probably sterilise her Therefore since laparotomy was going to be done, it was planned to protect the ovaries by moving them out of the direct beam of X rays and ensheathing them in lead For this purpose, lead 2 mm thick was shaped to resemble the two halves of a walnut shell The ovaries were expected to measure 2 0–3 0 cm long and 1 0–1 5 cm in the greatest width Two complete sets of shells were made one 2 25 × 1 25 cm the other 3 5 × 2 0 cm (internal dimensions) Each pair had a hole for the fallopian tube and broad ligament, and two small holes in each side of the half shells to enable the shells to be secured together and sutured to the abdominal wall Each part was then dipped several times in liquid latex to produce an innocuous coating for the lead

At laparotomy on Aug 15, 1952, Mr Twistington Higgins found that the neoplasm filled the pelvis , it was retroperitoneal, fixed, and very vascular, apparently a typical neuroblastoma The attempt to enucleate the tumour was eventually abandoned, a piece excised for section, and the peritoneal covering repaired The ovaries being unexpectedly large, a pair of shields had to be fashioned on the spot from sheets of lead of the same thickness shaped manually and covered with rubber finger cots The ensheathed ovaries were then sutured together and attached to the anterior parietal peritoneum as high as possible

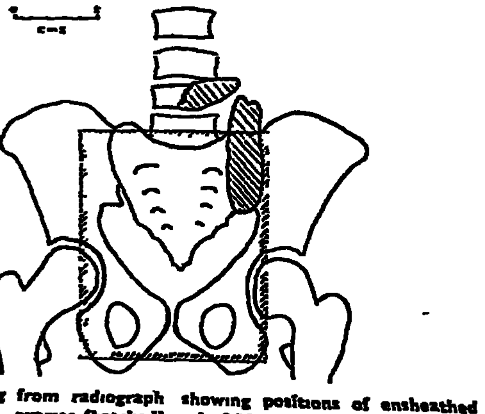

Fig 1—Tracing from radiograph showing positions of ensheathed ovaries (hatched) and of X-ray field
